ANEMONE FULGENS. (Pest-led).—Our correspondent need not be surprised to find a mixture of *Anemones* among what he has procured under the name of *A. fulgens*. The latter is a form of a very variable species placed under the oldest name of *A. hortensis* described by Linnaeus. At least five of the forms have been described by different authors as species. *A. fulgens* has fairly broad, brilliant scarlet or vermilion sepals, with black stamens in the centre. A somewhat similar form is *A. Regina*, with beautiful red sepals, rounded at the ends, but with a yellow zone round the black centre. *A. pavonia* has very numerous, sharply pointed sepals, with a small black centre and is sometimes named *A. fulgens flore pleno*. It has the colour of *A. fulgens*, but the sepals are too narrow and pointed for the true *A. fulgens*. The form with broad, rounded sepals like a Poppy would be the Poppy *Anemone* (*A. coronaria*) or a hybrid of it, for it has been proved that the two hybridise freely. All these forms grow promiscuously together in woods and meadows among the grass and are liable to be mixed when dug up. They should by rights be cultivated and separated before being sold. The red *Anemones* of the Riviera would be the same as the above, for they extend all round the shores of the Mediterranean, from France to Italy, Greece and Asia Minor.

TREES AND SHRUBS.

WISTARIA ATTACKED. (T. N., Bucks.).—The *Wistaria* has undoubtedly been attacked by birds, possibly bill-creepers. This and other plants can be protected by spraying with either paraffin emulsion or quassia and soft soap on a dry day in mid-winter.

PRUNING OF HOLLY HEDGE. (L. G. H.).—The month of May, when new growths are pushing freely, is the best time to cut back and prune a holly hedge. All the cuts or wounds larger than the little finger should be dressed with Stockholm or coal tar, using a small paint brush for the purpose. If the cuts made with the saw are rough, make the surface smooth with a pruning knife before applying the tar. After the hard pruning of a hedge it is generally considered desirable to apply a mulch of old decayed manure.

MOVING A LARGE NEW ZEALAND FLAX. (L. G. H.).—The moving and division of the large plant of *Phormium tenax* may be done now. Not being acquainted with the exact form of growth it is not easy to say into how many

pieces the clump may be divided. It should, however, be possible to divide such a large plant into four pieces. It may be easier, as our correspondent intends to divide it, to lift the plant in sections. Use a digging fork to separate the portions, not a spade as this would cut the roots. There is no reason why any portion should die, as many of the roots will pull out from under the wall with the growths. Water liberally after transplanting and particularly if the weather is at all dry this summer.

THE GREENHOUSE.

TOMATOES ATTACKED. (W. A. P., Fife).—The Tomatoes are attacked by the fungus *Phytophthora cryptogea*. This lives in the soil and flourishes especially when the soil is over-wet and the weather dull and close. Sterilisation of the soil is the best preventive. The tops of the diseased plants may be rooted as cuttings and grown on if there is any shortage of plants.

CYCLAMEN AND CELANDINE. (Kent Bee).—The corms of *Cyclamen* may be grown and flowered successfully for several years. This depends largely on the careful treatment of the plants after flowering. We have seen corms ten, twelve and even fifteen years old carry fifty to one hundred flowers. With age both flowers and leaves are not so large. It is usually a question of quantity at the expense of quality. The eradication of the *Celandine* from beds and borders permanently planted with bulbs is well nigh impossible. The only thing that can be done, short of lifting the bulbs and following the ground, is persistently to dig it out with a small handfork and to use a narrow hoe frequently between the growths of the bulbs so that the *Celandine* has no chance to produce leaves.

MISCELLANEOUS.

CURRENT BUSHES ATTACKED. (W. B., Hauts).—Aphis has caused the blistering of the leaves and spraying with paraffin emulsion will be wise, taking care that the spray reaches the aphides in the blister.

DUCKS AND WATER LILIES. (R. H. L., Durham).—We have not kept the domestic duck with Water Lilies, but have had wild duck, which bred on a lake with a good collection of *Nymphaeas*, and no harm has accrued, so we should have no fears of ordinary ducks. The great enemy of Water Lilies is the water rat, which will often eat the root-stocks in early spring.

FLAGEOLETS. (W. S. G., Braintree).—The Haricot Bean is a variety of *Phaseolus vulgaris*. The flageolet of the French is likewise a form of the same species. The following are the names of several of the flageolets recommended by Vilmorin-Andrieux et Cie., 4, Quai de la Mégisserie, Paris: Flageolet blanc, with long pods, described as of vigorous growth and production; 1. Chevrier; 1. Roi des verts; 1. rouge; 1. très bûtif d'Étampes, very productive; 1. blanc à longue cosse, described as the most vigorous and productive of the flageolets. Practically any French Bean gathered at the correct time, that is when the seeds are formed, but before they start to ripen, are satisfactory as flageolets.

NAMES OF PLANTS.—M. A., Taunton.—1 and 7, *Erica arborea*; 2, *E. lusitanica*; 3, *E. mediterranea alba*; 4, *E. mediterranea*; 5 and 6, Both forms of *E. Veitchii*; 8, *Primula marginata*; 9, *Ornithogalum nutans*.—"Rex."—1, *Viburnum* sp.; 2, *Lonicera* sp. We should like better specimens and more information as to the origin of these two plants.—G. L. Alwick.—*Piptanthus nepalensis*.

IRISES IN THE BORDER.

Irises are an indispensable addition to the herbaceous border. Here they should be planted in bold groups of a dozen or so of one or, at most, two sorts in a group. Even when the flowers are over the swords of green, often of grey-green, serve as a beautiful foil to other plants in bloom.

THE USES OF MATERIAL

I.—RHODODENDRONS AND AZALEAS

“There is a compelling reason in the uses of the plant, for every novelty of colour or form: and our art saves material by more skilful arrangement.”—EMERSON.

INTRODUCTORY.

THE cultivation of plants, trees and shrubs, keeping them in health and vigorous growth, the production of fine, well developed specimens, constitutes the *practice* of gardening. The use of them

in associating them with each other in such a way that each assists the other in forming a pleasing picture, is garden *art*. The production of the purest pigments, or the finest canvas is manufacture; the application of one to the other is art. The production of the finest specimen of plant life is merely its manufacture. It is just a process depending upon certain scientific knowledge, which, if properly applied will inevitably produce the required results. We have none too much of this application of science to cultivation in gardening. There is still too much “rule of thumb” in both the nursery and private establishment. Nevertheless, science in the garden is much more prevalent than art. The reason for this is that scientific knowledge can be acquired, and being applied, leads to the discovery of new truths.

Art is much more a matter of individuality. There may be laws and rules of composition both of colour and form, but their application varies with every circumstance. The path of science is a direct one, clearly defined and its laws are positive

and absolute. No such beaten track exists in the domain of artistic endeavour, in the garden or anywhere else for that matter. “If designing *could* be taught, all the world would learn; as all the world reads—or calculates,” said Ruskin in discussing “Modern Manufacture and Design,” and it can be applied to gardening with

equal force. Thus applied it merely points the moral that the best cultivator is often the worst hand at producing beautiful effects with his material.

And yet the whole aim and end of gardening should be to create such pictures that give a sense of satisfaction and pleasure, even to those who are

not blessed with the sense of knowing *why* they are beautiful, but simply feel that they are. The object of these notes is to indicate broadly how and where certain garden materials may be used to the best advantage, in a sense, pictorially. The details must be left to the individual and this is where the instinctive capacity for creative art comes into play.

It might be assumed from the foregoing that there is nothing akin between growing plants and using them successfully. The inference wrong. The truth is that though the paths to success are different, they are parallel, or indeed, often converge, and travel together. Both are absolutely dependent for their successes on the adherence to nature. Of what avail is it to make your garden picture of materials that will not survive the conditions in which they are placed? What is the use of achieving noble growth in a position in which it can never be appreciated owing to the unsuitability of the surroundings? The only real success in cultivation is reached by the

A FINE PLANT OF RHODODENDRON FALCONERI

discovery of, and adherence to Nature's laws. That, in garden art is only reached by the selection, possibly idealisation, but certainly reproduction of Nature's own effects.

NATURE'S TEACHING.

In applying these principles to Rhododendrons and Azaleas, the first consideration must always be the soil in which Nature grows them. There is an erroneous impression abroad that this is universally peaty. And yet one finds *R. ponticum*, the stock on which hundreds of thousands of the hybrid varieties are grafted, growing under all sorts of conditions and more often than not far removed from peat.

Nevertheless it must be conceded that the whole order Ericaceæ does appear to succeed in peaty soils in preference to others, but the very reason for this indicates why and how it can be grown with equal success in others. This order has almost invariably very fine fibrous roots. Peat, being of a soft open nature, permits the freest possible root action, but there is nothing in its chemical constitution that makes it preferable except, perhaps, that it is lime-free. But this indication of the preference of Rhododendrons, Azaleas, etc., for peat clearly suggests that in choosing the spot for them in the garden it should be one in which the soil is open, free and into which the innumerable fibrous roots will easily penetrate. Failing the existence of this the conditions must be made to suit.

The obvious places in which to find the required conditions are in or near woodland, where the leafy deposits of many years have created them. Or by stream and lake where rising floods and the subsequent recession of the water to its channel

leaves alluvial deposits of a gritty and open nature. And these are the very conditions under which very many of the species are found. An old writer, in describing the conditions most suited to Rhododendrons of certain classes, says: "Cool, loamy or sandy somewhat moist soils." The very root conditions that make them desire an open soil also make it imperative that there should be abundant moisture within reach. One other condition desirable for success with many varieties is protection from intense light and heat of the sun. Lightly shaded positions suit them best. Dense shade is fatal.

The garden Rhododendrons of to-day are nearly as involved so far as parentage is concerned as most other garden plants. This inevitably happens whenever there is a tendency to multiply varieties by hybridising. But there is one point that most of the original species have in common, and that is that they are found growing in near association with a liberal supply of moisture. This applies to such species as *catawbiense*, *ponticum*, *caucasicum*, and others, on which the foundations of the present marvellous collection of garden varieties were well and truly laid about a hundred years ago. At that time, Russell, Loddiges, Smith, Makoy and Waterer were the familiar names in the Rhododendron world.

So much for the indications of where and how they will grow, which, incomplete as it is, will serve for the present purpose, as it is merely a recounting of certain conditions that must be respected.

RHODODENDRONS.

Here is the first picture. Wooded, shadow-obscured lawns sweep down from the house to

the riverside. The slope being to the north-west the shadows have for the major portion of the day been cast towards the water side. Now it is evening and as the sun is low every ripple scintillates a sparkling gem. Just at the fringe of the lawn rises a glowing mass of Rhododendrons. Twenty-five feet high it lifts its utmost branches, and fifty or more it spreads itself right to the edge of the water, and beyond. Sheer to the water level, it drops a crimson curtain, its lower branches dipping in the lightly stirring wind to touch the surface, and cause outward circling ripples, dyed with the reflected colour of overhanging flower to a crimson wash.

Away to the right a smaller group, this time or pink with which mingles a few flowers of white, repeat the note, but in a different colour. Between the two the swards run clear to the water's edge, where, although it is yet early days, the young growths of reeds and rushes just fringe the line where land and water meet. Mingled together the pink and crimson would strike an inharmonious colour note, divided thus, each tells its own story in its own language of colour. Away beyond again are scattered masses, some small, some larger, but all alike creeping outwards to the setting sun and the water. As though jealous lest their magnificence should be wasted, they insist on casting a reflected glow around them.

Rhododendrons are never so beautiful as when they overhang broad sheets of water, be it river, lake or pond, but they are strong. So strong, indeed, that in certain lights they are inclined to give a sense of massiveness that is liable to detract from their beauty if unrelieved. Any considerable stretch of planting should therefore be broken by

SPECIMEN (UNGROUPED) RHODODENDRONS BY THE WATERSIDE.

erect growing trees, such as *Alnus*, *Taxodium distichum* or even the erect growing Willows. The whole art of using material consists in grouping contours as well as colour, and the rounded outlines of *Rhododendron* clumps cry out for the association of vertical lines. A wall of *Rhododendrons* may be striking, but it is not beautiful. Broken, scattered masses, interspersed with some such trees as above, or for a change a golden shower, in the form of *Salix vitellina aurea pendula*, will lose nothing in the way of colour effect, but gain infinitely in satisfying that sense of composition without which no picture is good.

The second picture is of a long woodland vista. Giant trees enclose the vision and direct the eye to the distant landscape. Towering Cedars rise black against the sky and many gnarled and twisted branches of Oaks cut silhouettes against the light behind, while their leafy tops form shadow mysteries around. The vista was cut through dense woodland, and here and there a single tree has been left standing, as though a forest tide had receded and left a giant seaweed stranded.

All along the fringe of woodland are gorgeous masses of carmine, crimson, pink, scarlet, purple, in ever-varying shades of colour, for it is *Rhododendron* time, and this is the place in which they love to grow. Years of falling leaves had left a deposit of humus on the ground, which when the clearing was made, became thoroughly incorporated with the loamy soil beneath. To assist root action a quantity of sandy gravel was mixed in the areas to be planted.

The groups have been so arranged that every advantage has been taken of the positions of trees, light and shade studied in the places allotted to the various colours, even the colour of the tree trunks behind has been considered in association with the placing of colour in front. Sometimes there is a little break in the continuity of the planting scheme, and the warm glow of *Azaleas* takes up the theme, but these are rarely used closely in association with *Rhododendrons*, because the strong orange, flame and yellow shades of *Azaleas* mar the deeper tones of *Rhododendrons*.

Such a place is just where *Rhododendrons* love to grow, and give of their best, because they are happy.

AZALEAS.

There is yet a third picture; again of woodland, but this time of paths winding among the trees, through gently undulating ways. Sometimes these paths pass through dense overhanging leafage, where even in these early days of the summer their shade is pleasantly cool. As a bend in the path is reached the eye is caught by a distant gleam of brighter light, and a second later a perfect riot of colour breaks on the view. Orange, crimson, scarlet, yellow, intense flame and indeed, every shade from pure white to the deepest crimson and purest gold. This is in a clearing in the woodland itself, and is filled with bold plantings of *Azaleas mollis*, *Ghent rustica*, *occidentalis*, and all the glorious hybrids that enrich the garden to-day.

The very shadows through which we pass to reach these open spaces, filled with intense colour, serve but to emphasize and intensify the gorgeousness of the effect. As the eye travels along among the brown tree trunks, blue and purple shadows and all the cool tones such conditions suggest, the distant colour, strikes a note that is something more than floral, and one thinks of the garden of the *Hesperides*, or some jewelled cave of the Arabian Nights. If the woodland were large enough there would be many such paths and many such terminations to them. How much more beautiful the plants themselves are when grown in such conditions can be imagined. How poor the formal shaped bed in a trim lawn, filled with even the best of the same shrubs appears in contrast! G. DILLISTONE.

THE ARRANGEMENT OF MAY-FLOWERING TULIPS

Changes in Taste—Modern Arrangements—Tulips by Themselves—Tulips in Combination with other Flowers.

NOT only does the present generation evince a new taste in the type of Tulip that it grows in its gardens, for corresponding to this its ideas about their arrangement in gardens are as different as they well can be. Once upon a time the Tulip-bed was the primary concern of all

In these notes we are concerned with the May-flowering varieties only. The magnificence and lordly bearing of the Cottages and Darwins have quite taken the shine out of the older "earlies," which once upon a time were so popular for bedding but which have gradually dropped out of favour. The new-comers may conveniently be considered

AT ALDENHAM HOUSE.

who fancied this flower. The position of the varieties in it was a matter of the greatest concern. The earliest plan of how the bulbs were to be planted is to be found in Samuel Gilbert's "Florist's Vade-mecum" (1682), where on page 77 he gives a detailed plan with names of how they should be set. Practically the same plan, as far as I can make out, was adopted by growers until somewhere about the middle of last century, when Groom of Walworth and other famous growers had their beds all carefully arranged so that the tallest plants were always in the centre row, and the roses, *bybloemens* and *bizarres* all carefully placed in order that they could be seen to the best advantage individually and as a whole. In Gilbert's time there were, probably, generally five rows in a bed. In Groom's day there were seven, and all the chief amateurs and traders erected Tulip houses for the protection of the blooms. There is a good picture of one in the *Gardener and Practical Florist* for 1843 on page 203, with details of its construction and dimensions. This is not the way we treat Tulips nowadays. Only a few of the old brigade, like Mr. Bentley, Mr. C. W. Needham and Sir A. D. Hall, have coverings for their flowers, but they are poor things compared with the sumptuous "houses" of the fanciers who lived in the early half of last century. Enough of these ruminations of the past. As the Cheshire proverb says, "I must love you and leave you." Practical politics are what is required. Allowed that the object of acquiring Tulips is garden decoration, what can be said to further this end?

in two ways; that is, when Tulips are used by themselves, and when they are used in combination with other plants.

(a) TULIPS BY THEMSELVES. Under this head first of all we have clumps in borders. An important point with these tall plants is the question of background. Why do Tulips in Mr. A's garden look so much better than in Mr. B's? It very likely is because they have something dark behind them which sets them off. No one grows hedges or builds walls and clothes them with verdure simply for the sake of Tulips, but all the same such things may be a mighty help. In what Bacon would have called prince-like gardens, whose dimensions are reckoned in acres, as, for example, that of Duffryn, near Cardiff, we may have different compartments all hedged round. One of these would make an ideal Tulip garden because the green surrounds are such a good foil to the coloured flowers. It is the same principle, whether it is a whole garden or a single clump. The setting should be considered. I once visited an old castle near Hythe. It had an immense courtyard surrounded on all sides with soft grey stone walls with narrow borders at their base. I thought how lovely great masses of *Pride of Haarlem* would look against them. So it need not always be a green background. The mellow red of the high walls of the large Rose garden at Balls Park would be the very thing for *Oliphant*, or *Duchess von Hohenberg*, or *Erguste*. Any grey-toned lilac or mauve might be used and, the result would be pleasing. Again, as to the size of the clumps, we must, of course, cut our

coat according to our cloth, that is to say, according to the size of the border and the depth of our pockets, but give me as large clumps as possible. I would rather have a few good-sized ones than a multitude of smaller ones. Six is my minimum number. For the maximum it is the algebraical sign "n"—ten, twelve or even more. A still further consideration about clumps is the harmonious blending of one with the other. Philip

(b) TULIPS WITH OTHER PLANTS.—This way of planting Tulips is very popular, although it is not economical, involving as it does the destruction of the carpeting plants or their removal to a nursery bed till they are wanted again. Some plants, it is true, which can be raised from seed every year may be thrown away without their loss being felt, as a fresh batch of seedlings will be coming on. Wallflowers and Forget-me-nots

like Lavender. (5) Tulip *Gesneriana major* (rich glowing crimson) with a groundwork of Arabis (white). (6) Tulip *Avis Kennicott* (rich yellow) mixed with such a Wallflower as *Blood Red* (deep red). (7) Tulip *Golden Bronze* (golden brown) with a good strain of orange Polyanthus. In this combination there is some risk in case the Polyanthus are past their best when the Tulip flowers, but it is so striking and out of the ordinary that it is worth trying. (8) Tulip *William Pitt* (deep red) with one of the variegated leaved Grasses mentioned above. (9) Tulip *Allard Pierson* (crimson maroon) rising from a bed of *Indigo Queen Forget-me-not* (deep blue). (10) Tulip *Oliphant* (silvery grey) with blue *Scilla hispanica*. (11) A late Tulip like *Inglescombe Yellow* planted alternately with a Daffodil like *Sir Watkin* (yellow). Such a bed gives two distinct shows and, if the flower-stalks of the Daffodil employed are removed after the flowers are over, there will be no eyesores when the Tulip is in bloom. (12) Beds of Roses may be thinly planted with cheap late Tulips, which can be cut off at the ground-level when their foliage begins to interfere with the new Rose shoots. If the bulbs can be taken up, so much the better.

The combinations that may be made are endless; but if they are to be a success a little thought is necessary lest we get, instead of pleasure when we see our arrangement bloom, the colour equivalent of a round peg in a square hole.

JOSEPH JACOB.

MAY-FLOWERING TULIPS ARRANGED WITH THE VIVID ORANGE CHEIRANTHUS ALLIONII.

Henry, the father of Matthew Henry the commentator, used to live within a stone's throw of my house. He built a garden wall which still stands. He kept a diary. At the end of one day he wrote "Thank God, no bad language heard to-day." Tulips are like workmen. When ill-assorted they have been known to swear, but whether it is at one another or whether it is really at their planter I hardly know. At any rate, let us try to avoid recriminations by considering before we plant or, better still, before we order the bulbs what will go together. An almost indispensable help is the R.H.S. "Report of the Tulip Nomenclature Committee, 1914-15." Every variety is pigeon-holed, and so if it is consulted it is comparatively easy to avoid pitfalls. Tulips look very well in large beds on lawns. In such positions suitable mixtures are very effective. They may vary from a simple combination of two varieties, such as the tall dark *Moralis* (Darwin) with the dwarf soft pink *Sir Harry* (Cottage) or, say, the rosy *Edmée* (Darwin) and the pale pink *Suzon* (Darwin), to a compound mixture made up of different shades of mauve and pink with just a few brighter colours to set them off. These are examples of how beds of Tulips may be treated if anything but one variety is wanted. It will be noted that in the combinations of two the varieties are of different heights. This variation tends to take away the stiff look that a strict uniformity almost invariably gives. In order to get at the heights and the times of flowering of the various Tulips the R.H.S. Tulip book which I have already referred to will be an invaluable help, as it gives for each the information required.

are cases in point. If the first named are sown in June and the last named in early August, the resulting plants should be about right for planting in October along with the Tulips in their flowering quarters. Attention to the time of sowing and to the time of taking cuttings of such things as *Aubrietias*, which should be taken about mid-July, is important, and must be studied if the best results are to be had. What are the plants most suitable for combining with Tulips? Wallflowers in variety, *Aubrietias* in variety, *Indigo Queen Myosotis*, *White Arabis*, *Polyanthuses* in variety (but only with the earliest of the May-flowerers), *Cerastium tomentosum*, early-flowering *Violas* and probably some of the *gracilis* hybrids, *Cheiranthus Allionii* (if sown in good time), *Centaurea Clementei* (grey foliage) in warm well drained gardens in the South, *Molinia cœrulea variegata* and *Arrhenatherum bulbosum variegatum* (two pretty variegated Grasses), and *Scilla hispanica* (blue, white and pink). The above list includes most of the more ordinary ones which may be used in bedding arrangements. Need I again say that it is very important to have pleasing combinations of colour—some will like harmonies and some contrasts. It is a matter almost entirely of individual taste. The following suggestions will, I hope, serve to put readers on the right track: (1) Tulip *Euterpe* (heliotrope) with pink *Scilla campanulata* (Spanish Squills) underneath. (2) Tulip *Palissa* (deep ruby red) with the orange *Cheiranthus Allionii*. I had this striking combination in my garden last year. (3) Tulip *Moralis* (violet purple) with a grey-leaved carpet plant like *Cerastium tomentosum*. (4) Tulip *Ergaste* (grey mauve) with a pale *Aubrietia*

PRESENT-DAY DAHLIAS

II.—THE DOUBLE-FLOWERED VARIETIES.

THE CACTUS TYPE.

AFTER the introduction of *Jaurezii*, the Cactus Dahlias soon developed into some unique forms of light, loose, artistic flowers with the most delicate colouring. The tendency with regard to this class was for some years to produce flowers of a large size, so large, indeed, that the weak stems could not support the heavy blooms, which were allowed to hang their heads among the foliage and, although grand when supported artificially on the exhibition table, were of little use for garden decoration. On the other hand, some raisers have been keeping steadily in view the greater value of this class with flowers of a more moderate size, produced in greater profusion on stiff stems with flowers thus carried well above the foliage. These varieties include *Burbank*, *Edith Carter*, *Empire*, *Mary Purrier*, *Mrs. C. Foster*, *Mrs. F. Paton*, *Mrs. Landale*, *Richard Box*, *Rose Queen* and *White Ensign*.

THE MINIATURE CACTUS.

This is a class exactly corresponding to the larger Cactus, only that the plants are dwarf and the flowers small and borne on stiff stems, thus rendering them valuable for garden decoration and for cutting. They include *Firefly*, *Gracie*, *Little Fred*, *Modesty*, *Molly*, *Niobe*, *Nord*, *The Bride* and *W. Marshall*.

LARGE DECORATIVE DAHLIAS.

Many intermediate forms known as Decorative have been steadily developed. Although double in form, they are much looser and lighter than the old Show Dahlia. The florets are flatter and not so evenly quilled with still a considerable number of florets closed round the centre. They are thus not so heavy and formal as the Show

sorts, and the flowers are carried well up on stiff stems. A few of the first varieties raised were Constance, Cochineal and Pieta Formosissima. These have all now been discarded for the better varieties as follows: Apricot, Delice, Papa Charmet, Pearl, Porthos, Queen Mary and Yellow King.

CAMELLIA-FLOWERED DAHLIAS.

A great trial of Dahlias was carried on at Wisley last summer jointly between the National Dahlia Society and the Royal Horticultural Society for the purpose of testing and comparing the many new varieties and of ascertaining their usefulness for garden decoration. A Conference was held in connexion with it, when some alterations were made in the classification of the types. One of the changes made was in the Decorative class. There was so much variation in size in this class that it was decided to divide it into Large Decorative and Small or Camellia-flowered Decorative. Many of the latter are so close growing and floriferous that they are exceedingly useful for

massing in large beds. Some of the best varieties are as follows: Crimson Flag, Barlow's Belder, Cheal's White and Reginald Cory.

DOUBLE SHOW AND FANCY DAHLIAS.

Readers would probably like to have a few of the best varieties named, which are as follows: Doreen, Gracchus, John Walker, Miss Ormerod, R. T. Rawlings, W. Garrett and Mrs. Rawlings.

POMPON DAHLIAS.

These are very small double Dahlias with very neat, globular flowers about 1½ ins. to 2 ins. in diameter. They are pretty either for garden decoration or for cutting. Some of the best varieties are as follows: Adelaide, Bacchus, Electra, Glow, Regulus, Nerissa, Ideal and Queen of Whites.

LARGE PÆONY-FLOWERED DAHLIAS.

This is a large class which has somewhat large and loose florets, which are usually somewhat twisted. Most of these varieties are strong,

tall growers, carrying their flowers well above the foliage, are particularly showy in the distance, and are most effective when grouped in masses in front of a dark background. They are also useful for cutting for the decoration of large halls, etc. Some of the best varieties are Aphrodite, Claudia, Gipsy Queen, Lorna, Louise and Mark.

THE MINIATURE PÆONY-FLOWERED DAHLIAS.

The description of this class is exactly the same in form of flower as the Large Pæony, only the flowers and plants are both smaller in size. Some of the best varieties are Chatenay, Baron Hayashi, Lady Betty and Mrs. S. Goldman.

CLEMATIS-FLOWLED DAHLIAS.

These represent yet another interesting break. The centre of the flowers consists of small quilled florets surrounded by wide flat petals, the total effect curiously resembling a Clematis. The best variety at present introduced is Ada Finch.

JOSEPH CHEAL.

A TYPICAL DECORATIVE, LADY DENMAN.

GLOW, A CHARACTERISTIC POMPON DAHLIA.

THE MINIATURE PÆONY VARIETY LADY BETTY.

CHEAL'S WHITE (CAMELLIA-FLOWERED).

THIS YEAR'S CHELSEA SHOW

Some suggestions and a forecast.

THE week that is coming overshadows, from some points of view, every other week in the gardening calendar. It is the week of Chelsea Show. Nor is that all. Chelsea Show is, of set purpose, arranged for a season when flowers are naturally most prodigally displayed, when rock garden and wild garden compete with shrubbery and more formal beds to make a display unrivalled in the cycle of the year.

True it is that the herbaceous border has not yet attained its greatest splendour, but even here glorious Irises and the May-flowering Tulips will be giving of their best, while the Apple orchards with their varying shades of pink and bluish transform the countryside. Some of their purely ornamental cousins will, no doubt, be seen at Chelsea.

One does meet individuals who frankly admit a preference for the relatively small fortnightly meetings at Vincent Square, which, given time, one can examine in detail, to the scenic splendours of the Royal Hospital Gardens which the three days of the Show—could one spare them!—are all too little to appreciate in detail.

Their attitude is understandable, but when all is said the exhibitor at the R.H.S. Hall is severely handicapped, if he wishes to achieve natural

Whatever special business, then, takes Mr. Smith or Mr. Brown to Chelsea, they are both sure to be found in company with one of the innumerable Mr. Robinsons comparing notes on the rock gardens. Visitors from a distance who are "doing" Chelsea for the first time this year will be well advised to see the exhibits in the tents before these become insufferably hot; after all, the outdoor exhibits will wait till they come! This may seem unnecessary, not to say trite, advice, but every year one hears perspiring visitors wishing they had "seen the tents first."

Exhibits at Chelsea may be roughly divided into two classes, those set up to show suitable arrangement of garden space and those intended only to display plants for sale. Exhibits in the first class are mainly but not entirely outdoors, and of the latter group 90 per cent. or more will be found in the tents. Since the model gardens are the main attraction, it has been thought well to supplement, as it were, in this issue the lessons they inculcate by articles on the arrangement of two typical races of spring-flowering plants, namely, Rhododendrons (including Azaleas), and May-flowering Tulips.

At the time of going to press it is still uncertain just how this season's exhibition will compare with those of previous years. The lateness of

There are mentioned below a few of the many features which will repay looking for, but the wise folk at Chelsea are they who, knowing the particular families or classes of plants which they wish to see and compare, study the official guide to the Show and inspect, first of all, the different exhibits in which they are specially interested. Afterwards they may enjoy the gorgeous banks of Orchids—supposing these not to be the flowers of special interest—and inspect the exhibition in general.

If a reliable census could be taken, it would be interesting to know how many visitors see the whole Show. To interpret "see" in a very strict sense might rule out everyone; but, to put the conundrum in another form, one wonders what percentage of those passing the turnstiles file past all the exhibits or even all the exhibits in the tents. It is astonishing how easy it is to think one "has done it all" when, as a fact, one has missed "chunks." Let us then reiterate that to be sure of not missing what one especially wanted to see one should carefully consult the official guide before beginning one's peregrinations.

It is hardly necessary to advise visitors to inspect the rock and formal gardens, but we understand that Messrs. Wallace of Tunbridge Wells are this year attempting something new. Instead of the rocky moorland scene so typical of rock gardens at Chelsea, they will depict a stream running through woodland and in its passage cutting its way through rocky strata. Adjoining this the firm will show a simple formal garden, and the whole arrangement should be particularly interesting and helpful to many garden makers in hilly wooded Surrey, for instance.

Something novel in formal gardens, at any rate as shown here, is promised by Mr. Klinkert of Richmond. In this garden there is to be no masonry of any description. Its place will be taken by the topiary, for which Mr. Klinkert's nurseries are famous.

For those who like blue gardens, and there are many who do, Messrs. Gaze's formal garden in tones of blue and grey will make appeal. The same firm will also have a rock and water garden on an ambitious scale, as well as a model hard tennis court.

Messrs. Cheal are again laying out a formal garden which will doubtless maintain their reputation. We understand that it illustrates the effective use of dry walling, while included in the scheme are Lily pools, shrubberies and herbaceous borders, with a pergola and summerhouse, and an avenue of topiary. An ambitious programme!

Of the exhibits within the tents no section is of greater general interest than that comprising the hardy fruit exhibits. Messrs. Rivers of Sawbridgeworth are hopeful of staging an exhibit of Early Rivers Plums, Duke of York Peaches and Cardinal Nectarines in pots, but the late season is rendering it difficult to get the needful finish in time. Messrs. Bunyard, on the other hand, always famous for their excellent fruit storing, are relying on an exhibit of late-ripening culinary and dessert Apples which should be of great interest to the private grower. Messrs. Laxtons, again, are staging Strawberries, including The Duke (which Messrs. Laxtons consider the finest Strawberry ever raised), Sir Douglas Haig, Marshal Foch and Lord Beatty.

Turning now to the floral exhibits, there should be an excellent display of the Queen of Flowers. Messrs. Frank Cant and Co. will stage some of their best novelties, including Mrs. Alfred West, a new Hybrid Tea Rose which they are distributing

THE NEW SALMON PINK PERPETUAL CARNATION EILEEN LOW.

effects, by want of time on the one hand and want of space on the other. The overwhelming attraction at Chelsea is undoubtedly afforded by the open-air exhibits of rock and formal gardens. Imperfect though these admittedly are—it is impossible, for instance, in the time at disposal to conjure adequate backgrounds—they convey to the eye of the layman ideas of form and of construction which he could hardly appreciate in any other way.

the spring has undoubtedly caused great anxiety to many exhibitors, but the recent change in the weather will, no doubt, do much to assist growers. As far as one can see and hear the annuals and Roses will be, if possible, better than usual, but it is probably too much to hope that the Irises, for example, will be as good as they were last year. Fruit, too, never overplentiful at this Show, will probably be shorter even than usual.

in June. This is exceptionally beautiful in the bud state when the shrimp pink blossoms are edged and suffused with coppery apricot and orange. Several other novelties not yet in commerce will also repay inspection, as well as the two Wichuraiana varieties—Snowflake and Yvonne—which in 1921 and 1920 obtained gold medals

Many visitors go to Chelsea solely to see the Irises. Despite the backward season, there will probably be numbers there as usual. Messrs. Wallace, at any rate, have made certain of theirs by cultivating them in pots. Those to be shown include some of the most recent Newlands seedlings, including Ann Page, Miranda and Regan, as

Herbertii—as they are often called. Mr. Herbert, like Mr. Douglas, never stages spectacular displays at these shows, but his flowers have a form, colouring and finish which make them fit for any floral company. They might be used to decorate the dinner-table of the most fastidious, which is more than can be said of most perfectly hardy flowers. Visitors should not miss this exhibit.

The Hardy Plant exhibits will no doubt be extensive, but the uncertainty of weather conditions makes a forecast impossible. Messrs. Blackmore and Langdon, however, expect to stage their super-excellent Delphiniums, including such varieties as W. T. Ware, Mrs. Townley Parker, Mrs. A. J. Watson and Mrs. Shirley. Numerous firms, including Messrs. Carter Page and Co. and Messrs. Cheals' will be exhibiting Alpines on staging. There will be many hardy Primulas; but those interested in these flowers should not on any account miss the exhibit of uncommon ones by Mr. MacWatt.

May-flowering Tulips will be largely shown by Messrs. Barr and Sons, who, determined not to "miss" the Show, have late as well as early-planted bulbs upon which to draw. This firm will also be exhibiting herbaceous plants.

Rhododendrons and Azaleas should be quite well represented. Messrs. Wallace are exhibiting the new "Kersbergen" Mollis Azaleas, of which several have recently received awards, also some of the best of the hardy Ghent varieties. Their Rhododendrons will include Pink Pearl, the new Hugo de Vries, and the always remarkable Doncaster, with other first rate sorts.

Dahlias will, even thus early, be something of a feature. They will be exhibited by, among others, Messrs. Cheal and Messrs. Carter Page.

Of greenhouse plants, particularly cool greenhouse plants, there will, as usual, be a fine display, which will, incidentally, demonstrate the ever-increasing ascendancy of hardy and half hardy annuals for conservatory decoration at this season. Messrs. Sutton and Sons will have a large informal group in a large tent adjoining the Embankment entrance. Their annuals will include Clarkias, Schizanthus, Nemesia, Phlox Drummondii, Mignonette, Godetia, Nemophila, Lavatera, Dimorphotheca, Love-in-a Mist (Nigella), Salpiglossis, etc., while they will have masses of other plants raised from seed, including pink and blue Cineraria stellata, Gloxinias, Begonias, Calceolarias and Streptocarpuses. Messrs. Sutton's last year won the Sherwood Cup for the most meritorious exhibit and their display is sure to be in the first flight this year.

Messrs. Carters always stage greenhouse flowers well at Chelsea. Their exhibit this year will include Calceolarias, Cinerarias, Gloxinias, Streptocarpuses, Clarkias, Petunias, Schizanthus and Spanish Irises, the whole edged with a broad strip of turf grown from their well known grass seeds.

Messrs. Blackmore and Langdon will stage their magnificent double Begonias, also hanging Begonias and Gloxinias. Their double Begonias will include such grand sorts as Mrs. J. Brunton, Queen of the Belgians, Nurse Cavell, Sir J. Wilson, Peace, Grand Monarch, Mrs. W. Cuthbertson, Mrs. T. Crawford, Mrs. J. Davidson and Lord Methuen.

Although old-fashioned in one respect it is only recently that garden lovers have fully realised how useful for both garden and conservatory Australian plants can be. Many of them, such as the Acacias (Mimosas or Wattles as the Australians call them), are hardy outside in sheltered positions, while the whole family are excellent for the cold, unheated conservatory, where they last a long while in flower. Messrs. Stuart Low are exhibiting a group which will consist of Acacias, Metrosideros (Callistemon), Eriostemons, Aotus, Leptospermums, Boronias, etc.

WICHURAIANA ROSE YVONNE WITH PINK SWEET-SCENTED BLOSSOM.

from the National Rose Society. Of the older varieties special mention should be made of the beautiful single Mrs. C. E. Salmon. Of a soft salmon pink, with orange suffusion and yellow base, it is especially charming for table decoration.

Mr. Elisha Hicks hopes to make a fine display with specimen climbers, dwarf Polyanthas, including the new varieties Lady Reading, Red Ellen Poulsen, Coral Cluster and White Orleans, and standard varieties in other sections, such as Premier, Columbia, Mme. Butterfly, Climbing Lady Hillingdon, etc.

In addition to the Strawberries already mentioned, Messrs. Laxtons are again exhibiting that charming single Polyantha Laxton's Pink Delight, which they exhibited so charmingly at last year's Holland House Show.

Messrs. Paul and Son (Cheshunt), Limited, will have an exhibit chiefly remarkable for fine weeping standards, pillar Roses and climbers. Noteworthy among these will be the novelty Perpetual Lemon Pillar, but many of the newer varieties of bush Roses will be included.

Messrs. Benjamin R. Cant and Sons will have their usual display of standard varieties and novelties. Among the latter may be mentioned the cream-white Phoebe (gold medal); the golden yellow Sovereign, with beautiful coppery tints in the bud state; the large and handsome Rev. F. Page Roberts, also a gold medal Rose, with flowers of the shade of that old favourite, Maréchal Niel and Mrs. Oakley Fisher, with most of the characteristics of the "Irish" singles, but flowers of the golden orange hue of Lady Hillingdon.

Messrs. Wm. Paul and Son, the Waltham Cross firm, will stage a group of Roses—"weepers," pillars, standards and dwarfs—many sorts being of their own raising, including Paul's Scarlet Climber and Ophelia, and their novelty for 1922—Gloria.

well as a collection of the Bliss varieties, among which Dominion, Dimity, Dusky Maid, Glitter, Tom Tit and Azure are especially noteworthy. Messrs. Barr and Sons will also be among those exhibiting these wonderful flowers.

With regard to Pinks and Carnations, we are on surer ground. Messrs. Allwood are making every endeavour to eclipse all previous displays they have staged in these gardens—not an easy feat by any means. Flanking their great group of Perpetual Carnations but separated from it by walks will be Allwoodii displayed on rockwork, including the new varieties Marion, Maud, Eleanor and Hugh. They are also showing a circular bed filled with specimen plants of Allwoodii, some of them half a yard across.

Messrs. Stuart Low and Co. will, as usual, show their perpetual-flowering Carnations, including the disease-resisting White Pearl and a new seedling from their well known variety Eileen, which, a shade darker in colour than the American variety Laddie, and called Eileen Low, is expected ultimately to prove a profitable market sort as it is exceedingly prolific. Other novelties will be the glowing cerise Reginald Cory (not yet submitted for award), Mrs. R. Gerrish (apricot), Sheila Greer (said to be an improved Fire Glow), Lord Lambourne (a very intensely coloured red) and Mrs. Myles Kennedy (said to be the sweetest smelling of all Carnations).

Mr. James Douglas will exhibit his Border Carnations and Cloves, of which it may be said that year by year the Borders grow stouter of footstalk and more robust of habit, while season by season the colour range of the Cloves grows wider.

Mention has already been made of those free-flowering hybrid Pinks the Allwoodii. Readers of THE GARDEN seem often to confuse these with Mr. Herbert's Carnation-like Pinks—Dianthus

Daffodils and Saxifrages at the Royal Horticultural Society's Hall

THE entry on the Fellows' passes of the R.H.S. for May 9 and 10 led many to expect to see Saxifrages in the ascendancy, but it was to a great extent, a Daffodil Show—such are the tricks our climate plays those who attempt to forecast the seasons and their floral offerings. But it was a very beautiful Show, and while Daffodils were in the ascendancy, there was a sufficient variety of other flowers to interest all tastes.

Messrs. Barr and Sons made history by winning the coveted gold medal at three successive meetings with the same flower. Although their large exhibit of Daffodils was not quite of the super-excellent quality of a fortnight back, it was a truly wonderful exhibit. Quantity and quality were combined with great variety and interest. As in most other instances the collection was noteworthy for the excellence of the many varieties possessing vivid coronas. Of these Nysa, Cœur de Lion, Angela, Red Gauntlet, Suzette and Prince Fushimi may be named. The Poeticus sorts were also admirable, and so were such large trumpets as Olympia, G. P. Haydon and Alope.

Not far from the above Messrs. J. R. Pearson and Sons had a magnificent collection which, with memories of the splendid display they made at the Spring Bull Show, made many Daffodil lovers wish the journey from Lowdham were shorter, so that we might see such beautiful blooms more often. This exhibit was said to be solely from home-grown bulbs, and it demonstrated clearly that with Daffodils the results are fully equal to any from the Continent. Of the many sorts on view we selected Nannie Nunn, Gipsy Queen, Croesus, Lucifer and Marshlight as being particularly brilliant, while such Poeticus varieties as Thelma, Acme, Firetail and Virgil were all that could be desired.

The decorative value of Daffodils of all types in skilful hands was splendidly illustrated in Messrs. Suttons' exhibit. Besides massing such sorts as Tritoma, Red Lady, Memento, Whitewell and Horizon, they had fascinating stands of mixed sorts which showed that it is not necessary to grow large quantities of separate varieties to be able to have attractive decorations. The Donard Nursery Company, on the other side of the entrance, aimed at a collection of the best sorts, and in this they succeeded admirably.

It was such as Cossack, Firetail, Flinstone, Crimson Braid and Curlew that, by reason of the brilliancy of their coronas, demanded admiration in Mr. W. B. Cranfield's collection, though there were many others worthy of attention. In an extensive contribution by Messrs. Ryder and Son, we noted many of the Tazetta section, including some promising seedlings.

The newest in a smaller collection by Messrs. F. H. Chapman seemed to be Orgy, which is a suggestive name in view of the orange shading on the broad corona. Messrs. Bath had a fine exhibit which included Firetail, Matchless and Unique in excellent form. On the Anglesey Growers' exhibit noteworthy varieties included Vixen, Lanten, Jingle, Jovial and Jester.

Although Saxifrages were not in sufficient numbers to make a great show, the R.H.S. brought from Wisley a comprehensive collection of the different types. Besides such showy sorts as Wenlock, Best of All and Pink Beauty, which are exceedingly decorative, there were specimens of such large-leaved sorts as *S. peltata*, which is an admirable plant for the bog garden, and *S. tellimoides*, with *S. lingulata* and its relatives,

Bellardii and *lantoscana*. Among general collections of alpine ones could pick out other good Saxifrages, Messrs. Waterer Sons and Crisp included *Wallacei*, *sanguinea superba*, *Diane* and affinis.

Gazania montana, which has narrower leaves than *G. splendens*, and bears sulphur yellow flowers, was interesting in Mr. M. Pritchard's collection, where the quaint *Podophyllum Emodi majus* was also to be seen.

The Blue Gentians were finely shown by Mr. Clarence Elliott, who also had a few plants of the rare *Sisyrinchium filifolium* and the tiny yellow *Viola biflora*; while Messrs. Ladhams, Limited, specialised in their brilliant bedding Daisy, Ball of Fire.

Next to an admirable collection of Lilies by Mr. J. C. Allgrove, it was the branches of Flowering Crabs in such exhibits as those by Mr. R. C. Notcutt and Messrs. J. Cheal and Sons that attracted attention among the general shrubs, though there were also many desirable double-flowered Cherries to be seen, and Messrs. Wallace and Co. again showed a number of their gloriously beautiful *Kersbergen* Azaleas with the handsome *Rhododendron Hugo de Vries*.

The less hardy *Rhododendrons* were the subject of an interesting exhibit by Dame Alice Godman, South Lodge, Horsham. The most beautiful was an unnamed seedling of vivid pink colouring, though the most perfect truss was the large white *Aucklandii* hybrid. The yellow *R. campylocarpum* and *Luscombe splendens* were also admirable. In Messrs. Gill's collection there was a grand plant of the large-flowered *R. Nuttallii*.

Roses and Carnations continue to be shown in great beauty, and Mr. James Douglas had a selection of his famous *Annulatas*. The variety he selected as one of the very best was Anthony, a fine yellow self, though we liked the wonderful colour of Brilliance, in which the bright cerise was set off by the mealy leaves.

The only exhibit of fruit was a collection of late Apples by Sir Montague Turner, Bedford's,

Havering, Romford. The dessert sorts included Duke of Devonshire and Scarlet Nonpariel, while Annie Elizabeth, Laue's Prince Albert and Newton Wonder of the culinary varieties were also plump and of good quality.

From the Chalk Hill Nurseries came an exhibit of excellent Pansies. These were grouped on the ground and attracted considerable attention.

NEW AND RARE PLANTS.

Aubrietia Glory of the Garden.—A very showy and floriferous variety which may be said to be

MYRIAD GOLDEN BELLS OF SOPHORA TETRAPTERA.

AN ADDITION TO FLOWERING APPLES—PYRUS ELEIYI.

an improved Dr. Mules, and would no doubt be even more effective in the garden than it was indoors. Shown by Mrs. Lloyd Edwards.

Azalea Korang Yuki.—This is apparently the native name of the Azalea Kämpferi variety—one of the many forms of this variable species, which have become known as Kurume Azaleas. It is a beautiful little bush bearing many smallish salmon-vermilion flowers. Award of merit to Mr. R. C. Notcutt.

Marguerite Golden Mrs. F. W. Sander.—This is a pale golden sport from the well known double white Marguerite and is recommended for window boxes and for summer bedding. It is a very floriferous plant. Shown by Messrs. Sander and Son.

Erinacea pungens.—Most alpine gardeners find some difficulty in inducing the "Hedgehog Broom" to flower at all freely, but Mr. Prichard was able to show a rounded bush quite 20ins. across and densely furnished with lilac, pea-shaped flowers. It was introduced from Spain in 1759, but is still a rare shrub in gardens. Award of merit and cultural commendation to Mr. M. Prichard.

Narcissus Firetail.—This well known and "best of all Barrii" varieties already had received an award of merit and now gains the highest award. It was splendidly shown. The flowers were all very large, of beautiful form and the dark orange coronas were almost blood red at the rims. First-class certificate to Messrs. F. H. Chapman, Limited, and the Anglesey Bulb Growers' Association.

Narcissus Pelican.—A very handsome Barrii bloom of large size and possessing plenty of substance. The perianth is primrose coloured and the cup-shaped corona is rich orange yellow. Award of merit to the Anglesey Bulb Growers' Association.

Narcissus Sea-Shell.—A chaste and beautiful Leedsii bloom. The perianth is white and the large, widely open corona is sulphur yellow deepening to deep primrose at the margins. Award of merit to Mr. W. B. Cranfield.

Narcissus Silver Salver.—The most distinct Leedsii blooms in the Show. Except for the suggestion of pale green in the very centre of the flowers they are pure white, and so it might well be termed a white Poeticus Narcissus. Award of merit to Messrs. F. H. Chapman, Limited.

Narcissus White Coral.—A Leedsii bloom in which the corona is nearly equal to the perianth. It is of milk white colour and is a very charming flower. Award of merit to Mr. W. B. Cranfield.

Primula fasciculata.—A pretty little Primula somewhat like a paler Primula rosea in the early spring that has slightly separated petals. The plants, which were only a few inches high, make little tufts of shining green spatulate leaves on rather long, fleshy stalks. The bright rosy mauve flowers are rather variable in colour and have a small yellow eye. Award of merit to the R.H.S.

Prostanthera rotundifolia.—This is one of the Australian Mint Bushes or Mint Trees, so called because they have resinous glands which are usually strongly scented. It is a tender, elegant little erect shrub which bears small green leaves on rather long stems. The purplish-mauve flowers are uncommon and quite pretty. Shown by Messrs. R. Veitch and Sons.

Pyrus Eleyi.—A seedling Crab which might be termed a glorified Pyrus Malus purpurea. The flowers are larger and brighter in colour than that well known spring-flowering little tree, and it also possesses the attractive purplish tinge to the young foliage. Raised by Charles Eley, Esq.; exhibited by Mr. R. C. Notcutt; award of merit.

Rhododendron sino-grande.—As the name implies, this is a Chinese form of R. grande, though in some particulars it might be termed a glorified R. Falconeri, which is, by the way, a very variable species. Even out of flower it is a handsome shrub, as the lustrous green foliage is very large and

silvery underneath. The big truss bore many white, veined, bell-shaped flowers on long woolly stalks. Unfortunately it is not a hardy plant, except in very favoured places. Award of merit to Dame Alice Godman.

Rhododendron William Watson.—This exquisite hybrid between R. Ascot Brilliant and R. Uplandii was not put forward for the award which, if presented, it must have received. The colouring is very remarkable, the major portion of the flower being blush, but the points of the petals are of deep reddish pink shade, thus affording a striking contrast. It has excellent foliage and is said to have proved hardy in several not especially favoured localities. Shown by Messrs. R. Gill and Sons.

Rose White Ophelia.—There can be no question but that this is a sport from the valuable Ophelia Rose, for it is identical in every way except that it is very much paler in colour. Though we should scarcely term it a White Ophelia, it is a chaste and beautiful bloom. Award of merit to Mr. E. J. Hicks.

Sophora tetraptera.—A glorious branch of this half hardy shrub, densely furnished with its pea-shaped deep golden flowers, was shown. It is a native of New Zealand, and except in the very warmest parts of this country must be given the protection of a south or west wall. Occasionally the handsome flowers are succeeded by curious necklace-like seed pods. Cultural commendation to Messrs. R. Veitch and Sons.

CORRESPONDENCE

THE TALLER CAMPANULAS.

MISS JEKYLE'S interesting article upon the taller Campanulas is a most useful one for lovers of hardy plants. Spetchley Park, famous for the wonderful race of hybrid Primroses, is also the home of improved developments of many of our hardy plants. Mrs. Berkeley is a born hybridist, and her unerring selection of the best forms has always filled me with admiration. Campanula lactiflora type is rather washed out in colour and is said to have been named from its resemblance to the bluish hue of London milk. Mrs. Berkeley has for some score or so of years selected and grown on her seedling Campanula lactiflora until she has a fine race of stiff-stemmed plants which stand of themselves, unless an unusually heavy rainstorm sweeps over the garden when they are in full flower. She grows pure white forms some 8ft. in height but, the pride of the species is the grand erect deep-coloured variety which is often 10ft. high, with large open-mouthed bells of rich purple, and seen in a mass as grown at Spetchley it is a glorious sight not easily forgotten. Campanula lactiflora used to grow exceptionally well at Edge Hall, and in one corner of the garden the tallest of the plants were well up to 12ft. or 13ft.

At Warley I have some plants with Soldanella-like flowers, but this is not an uncommon occurrence. — E. WILLMOTT.

LONICERA NITIDA.

UNDER the heading "A Valuable Evergreen," Mr. H. C. Wood asks for the experience of amateurs with this shrub (page 218). Our experience here is that, in view of the vast number of better things it is not worth the ample space which it claims. The foliage, certainly, is neat, but the flowers are so inconspicuous as to be negligible; the berries, however, are a very pretty, translucent anethyst purple, but they are so small as to require to be produced more abundantly than has ever happened here to be of much account. On page 219, Mr. E. Shoosmith writes disparagingly of Oleanas as "never very beautiful." This is a singular verdict upon a genus containing such charming evergreen shrubs as O.O. macrodonta, nummularifolia, nitida, illicifolia and semidentata. It is true that these prosper only in mild districts, but O. Haastii is much hardier and makes a fine

show when sheeted with chalk-white blossom in August.—HERBERT MAXWELL, *Monreith*.

THE SINGLE ARABIS.

THE old white Arabis, A. albidia, is too rampant a grower to be useful near plants with any

A DRY WALL CLOTHED WITH ARABIS.

pretensions to being choice, but it has its uses, none the less. It seems nowadays largely to have been ousted by the even more rampant double variety, which is certainly more lasting, but is otherwise less desirable. For smothering clinker-built banks or unsightly retaining walls it is truly excellent, but it should not, of course, be largely used where the wall material has any intrinsic beauty. The picture, I think, well illustrates its "hiding up" potentialities.

There is now a fashion to run down the whole Arabis family, but A. ambretioides is a lovely and not at all rampant plant and some of the still smaller forms, such as A. Sturii, are favourites of some who know Alpines really well.—E. N. Q.

MONOTONY IN GARDENS.

THIS is a subject that has been written about to any extent, and I am afraid that the people who need teaching how to get some variety into their gardens are those who never see a gardening paper. I find that though my pupils all seem to have gardens at home, they are all unacquainted with the majority of my plants. I think that outspoken criticism of dull gardens, if done tactfully, is the only way to rouse general amateur gardeners to a sense of the appalling dullness of their own gardens. This powder, if followed by the jam of promised seedlings and cuttings, is swallowed quite calmly. It is also a good plan to exchange small plants with friends living at a distance, as every neighbourhood seems to favour some particular group of plants. Even cottage gardens vary in different parts of England. This is, I know, partly a matter of soil and climate, but not entirely. The *Chœranthus* family is very long-suffering, and yet how often does one see any member except the double or single *C. Cheiri*? I wonder if any readers of THE GARDEN can tell me where to get the green winter-flowering Hellebore. I had so much of it in Hampshire that I was careless of it and only brought away one small piece, which was destroyed while I was away in the summer. Now I am miserable not to be able to find it again anywhere. It is one of those January-flowering treasures that are apt to be forgotten at planting-time, as one does not miss it until winter comes. Very few gardens seem to have it, but I saw quantities of it in Shakespeare's garden at New Place. Another wild plant which I always found very useful to fill up in poor positions under trees is the variegated *Bitouy* and that I have also lost.—ETHEL CASE, *Saanage*.

AN INVALUABLE TREE.

TO lovers of flowering shrubs I would say, plant *Prunus Magellanica* (that was the name it was given when I bought it some years ago). It has already blossomed twice this year, and my gardener tells me it will bloom again at mid-summer. Branches of it keep fresh in vases for so long, and I tell him to layer it and propagate it in every possible way, for it is so gay in black winter months.—F. L., *County Dublin*.

Our correspondent's tree is doubtless *Prunus microlepis*, generally known in gardens as *Prunus Miqueliana*, though from *P. Miqueliana* (*Maximowii*), it is quite distinct. It is sometimes considered a form of *P. subhirtella*, to which it is, in any case, closely related. Lady Moore referred to this beautiful tree in our issue of February 11, 1922, page 64, and it was illustrated in THE GARDEN last autumn as *P. subhirtella autumnalis* (October 8, 1921, page 502).—ED.]

NARCISSUS DEFORMITY.

I WONDER if any of your readers have had the same experience with *Bernardino* Narcissus this year as I have. I have about fifty of this variety, and nearly every bloom which has opened has been deformed and a great many buds have been "blind." I believe one of the parents of *Bernardino* is *Lulworth*, which is very apt to be deformed and have eight petals.—H. G. HAWKER, *Ivy Bridge, S. Devon*.

THE DAFFODIL SEASON OF 1922.

SURELY this has been the strangest Daffodil season on record. In February I said to my head man: "It is going to be an early season; the growth is so forward that nothing can now keep it back." I ought to have known better, and to have called to mind past Aprils, such as the one when Mr. Engleheart's Daffodils were all buried under about a foot of snow; that is,

all but one King Alfred, which was very tall and was tied to a stick! Also, another season when a heavy snowstorm was falling as we left the Birmingham Show about April 25. To return to the present season. We kept thinking that the weather would certainly change, but if the wind did get out of the east for a few hours it was soon back again. We hoped to exhibit in London on April 10; there were then about four or five varieties of early trumpets in bloom and that was all. "Well, we will get to Birmingham on April 20 and London April 25." The best laid schemes of mice and men, etc. Some fifteen nights of frost in succession acted like cold storage, and we had to attend both these meetings without any flowers. At long last as I write (May 6) we have cut a very good lot of blooms for Vincent Square, May 9, in spite of more frosts and two or three gales. I said to one of my friends some years ago that a Daffodil grower's year was "eleven months of waiting and one month's pain."

Does not this season verify the above? The wonder is that after all this frost, hail, wind and other bad forms of weather many of the Daffodils have come to perfection and even above their average in size and form, while some of the earliest trumpets are still flowers of a sort after enduring

nearly twenty frosts and having been out for quite a month. A curious thing is the effect which this retarding season has had upon the relative blooming periods; early, late and midseason have all been out together. To show this I give a list of the varieties cut for market by my firm on May 4, and all these were fresh flowers in really good condition: Mrs. Langtry, Argent, Emperor, P. R. Barr, Empress, Horsfieldii, Lucifer, Frank Miles, Minnie Hume, Florence Pearson, Fairy Queen, Giant Leedsii in variety, Evangeline, Lulworth, Autocrat, Mme. de Graaff, Amazon, John Bain and Poeticus precox grandiflorus. It is not often that *Horsfieldii*, Mme. de Graaff and Lulworth can be cut in good condition on the same day. A very early and a very late season seem to have much the same effect upon the relative times of flowering; the one rushes all out together, the other keeps all back to one date.

Well, I suppose we poor Daffodil enthusiasts—maniacs some of our kind friends and relations call us—will go on growing and worshipping at the shrine of our queen of spring flowers as long as we are able to get about at all, in spite of bad weather and all the other troubles which beset us, always looking and hoping for that perfect April which never, never comes.—J. DUNCAN PEARSON, *Lowdham, Notts*.

GARDENING OF THE WEEK

FOR SOUTHERN GARDENS.

The Kitchen Garden.

Salads.—To maintain a constant supply of Lettuce, Radishes, etc., during the early part of the season it is absolutely necessary to have the aid of some cold frames, but from the present time all hardy salads may be raised outside. The place devoted to them at the commencement of the season should be a warm border and the soil made as light as possible. If light skeleton frames can be arranged for so that a covering may be given at night, so much the better, or shelter may be obtained by spacing the early rows of Peas and Broad Beans so that a row of salads may be grown between them. On light soils during the hottest weather it will be found best to sow Lettuce seeds thinly where they can grow to maturity, and avoid possible losses from pricking out when the weather is dry and unfavourable for such seedlings to become re-established.

Thinning out of Carrots, Parsnips, Onions, etc., should be proceeded with as each successive sowing becomes sufficiently strong, choosing showery weather for such work if possible. No hard and fast rule can be given respecting such work, as it is entirely a matter of thinning to suit each grower's requirements.

Marrows may now be planted on beds prepared as advised a few weeks earlier. Where a couple of frames can be spared several weeks will be gained by placing them over the plants on the bed for a month or so. Marrows will also do quite well on the level ground. One of the best crops I have ever seen was grown in this manner by a small farmer in Monmouthshire who marketed considerably over two thousand fruits during the season. It is always advisable to keep a few Marrow plants in reserve until June is in, for one cold night may spoil all early plants.

The Flower Garden.

Liliums that have been given a start in pots previous to planting out in the herbaceous border or other positions may now be placed in their flowering quarters. Where the soil is of an unsuitable character it should be replaced with a compost of fibrous loam, peat and leaf-soil, taking care that the drainage of the position is in good order.

Staking.—The staking of many border plants will demand attention at frequent intervals and such work should be carried out with the least possible display of supports so long as there is sufficient to hold or train the plants as desired. Anything approaching making besoms or faggots of the various plants should be carefully avoided, and if a few stray shoots are left untied no very serious crime is committed. A far greater one is to make each plant or shoot to have the appearance of "standing at attention."

Planting.—Three good plants which may be got into their flowering quarters as soon as convenient after this date are *Cannas*, *Calceolarias* and *Salvia patens*. The first named is an excellent plant, and may be used in a bed or as relief plants among dwarfier plants. In a streamside or woodland bed they are fine with Tiger Lilies. *Ampelxicaulis* is, I think, the best of the *Calceolarias*, and as a bush or standard can be effectively used with other plants. It associates well with *Heliotropes*, *Streptosolen Jamesonii* and *Salvia patens*, and should it be planted where an edging is required, one with a silver-grey tone is pleasing. *Salvia patens* is one of the most effective blue bedding or border plants we have, being equally at home in the mixed border as in a formal bedding arrangement. Its lovely rich tone will be seen to greater advantage if the plants in its immediate vicinity have a somewhat quiet colouring.

Fruit Under Glass.

Inarching Vines.—This operation may be performed when the plants are resting or when in active growth, and the latter is certainly the safest, and is a very good way of introducing new blood into a permanent viney. It is the union of two growing shoots of about equal thickness, and is carried out by cutting away a portion of the stock and scion at the proposed place of union for a length of about 3 ins. until they fit into each other perfectly, in which position they should be securely bound and kept so until the union is thoroughly secure. The scion should then be gradually severed from its own root and the stock Vine not allowed to make much growth but forced rather to concentrate all energy upon the scion.

H. TURNER

(Gardener to the Duke of Northumberland),
Abby Park Gardens, Guildford.

FOR NORTHERN GARDENS.

The Kitchen Garden.

Brussels Sprouts.—Plant out the main batch of these which have been raised in frames. Allow 3 ft. between the rows and 2 ft. between the plants in the row, as when given generous treatment a wide spread of foliage results. Brussels Sprouts enjoy a lengthy season of growth. The soil between the rows should be cultivated freely before finally earthing up.

Asparagus will now be pushing up strong heads as the warmth increases. Keep the beds clear of weeds and encourage weak plantations by sprinkling a quick-acting fertiliser through the bed. Soot is also a commendable stimulant. Beds that were planted during this spring should be given a light mulch of half-rotted horse manure so as to prevent evaporation during hot weather. Thin seed-beds, as it is essential that no overcrowding take place. Stir the soil between the lines with a hand cultivator and water freely.

SOME EARLY BROOMS and other THINGS

FULL as your spring garden may be with fragrant flowers, I do not think there is anything of its time whose perfume is so all-pervading as *Cytisus præcox*. Sun and heat it wants, of course (what Broom does not?), and these we have had this year, in May's first week, just in time for this lovely shrub to give us of its sweetness with unusual prodigality. *C. præcox* has inherited the rich fragrance of one of its parents, *C. purgans* of the Auvergne, and the grace of the other, *C. albus*. The latter need not be extolled here, but I think some of us might extend a little more appreciation towards the former and for these reasons. It is a close-habited, neat little bush 3ft. to 4ft. tall, hardy, easily grown and one of the earliest of its race to flower. It enjoys a really hot place. Give it that and it will be a flaming mound of rich golden-yellow in April, or earlier; it will remain in flower a long time and be indescribably fragrant all the while.

C. Ardoini is a rock garden gem that will insist on being given its due recognition by the brilliance of its yellow beauty and freedom of blossom. It was this shrublet and the white Broom which gave us the charming hybrid, *C. kewensis*, an elegant, prostrate Broom which bears its clusters of ivory blossom about the same time as the above. There is something peculiarly refined about *C. kewensis*. Another good dwarf Broom which has this year, at any rate, made good its claim to be counted among the earliest is *C. decumbens*. It is very prostrate with a distinctive silky foliage and copious spikes of large yellow flowers.

Cytisus mouspessulanus (*candicans*) is a member of this clan which ought to be more widely grown,

for while it is quite hardy, it has all the good points of *C. fragrans*, to which it bears a very close resemblance. This graceful, leafy shrub grows to a height of about 6ft., but it begins to flower when scarcely out of the seedling stage and increases in beauty year by year. The first blooms usually appear in April, the shrubs attaining their full prolificacy at the end of May, but a succession of flowers is maintained pretty well right on to autumn. *C. mouspessulanus* is not long lived, but it comes so easily from seed sown in the open and grows so fast that it is an easy matter to maintain a stock and to grow it in large groups. Like most others, this species enjoys a light, warm, stony soil and an open situation, but it does not object to thin shade.

Writing of the days before the Azaleas (save the Japanese kinds in the rock garden) have begun to overwhelm all else about them with their colour and scent, those spring-flowering *Berberises* which are most notable for their blossom rather than their fruit are always conspicuous. The respective

splendours of those two rivals, *B. Darwinii* and *stenophylla*, defy comparison, though one is not forgetful of the fact that there are good, better and best forms among both. So to the lesser lights, to *empetrifolia*, an attractive little shrublet which (with *Darwinii*) gave us *stenophylla*, and on to the many hybrids of the last named, many of which are well worth attention. Then there is *B. buxifolia* (*dulcis*) with its dwarf variety, *nana*, both well known, but none the less estimable on account of their compact growth, deep green, glossy foliage, and the large and early flowers. *B. s. Irwinii* might be described as a diminutive *Darwinii*, and with that recommendation one need not say any more. It is an ideal, early-blooming, rock garden shrub. Yet another of this inexhaustible family to which is due at least a passing notice is *B. pruinosa*, whose arching wands are so prettily hung with their fine yellow globes (and as often as not the glaucous last year's fruit) throughout the middle period of spring. *Camellia Donckelaarii*, which has been

flowering since early April, is still (four weeks later) a conspicuous object in the woodland, the large crimson-scarlet rosettes having an admirable background in the rich green of the foliage. Near this shrub a stripling *Magnolia conspicua*, var. *superba*, is bearing one of its wonderful blooms at the tip of almost every twig and, in striking contrast to the rather stiff and naked Yulan, the long, arching wands of *Exochorda grandiflora* sweep towards the path in a cascade of purest white and soft grass-green foliage. Though as leafless as in the dead of winter, a Judas Tree (*Cercis Siliqua-strum*) is here beginning to blush redder day by day with the rose-purple blossoming spurs which are opening on twig and branch.

THE UNCOMMON DEEP GOLDEN BROOM, *CYTISUS PURGANS*

Pyrus (*Malus*) *floribunda* rises like a little cloud of pink beyond a group of double Gorse which adorns a distant bank, while in the middle distance, lighting up the shade of woodland trees, is a grouping of *Fuphorbias*, most striking of which is *E. polychroma* with heads of brilliant yellow.

* The winter-spring Heaths having come nearly to an end with *Erica mediterranea*, var. *superba*, thus keeping the "good wine" to the last, there might be a break in the succession of these delightful plants until the summer bloomers begin. But *E. australis* fills the gap at this stage and none could do it better. For few, indeed, are the taller species or varieties of this fascinating race which can rival *E. australis* in colour, foliage and distinction. *Bryanthus empetrifomis* is also at

its best at this intermediary period. As for the Azaleas, one does not enter their territory without hesitation, but a passing notice must be made of one or two of the very first to flower. Among these I have an affection for the old *A. amœna*, even if its crimson is a little keen. It is so lavish with its blossoms, so undisturbed by unkindly weather, and after all the hybridist owes it much.

The familiar *pontica* is widely grown in woodland for the sake of its perfume and early blooming. *A. ledifolia* var. *narcissiflora* is another that comes among the forerunners of its kind, and surpassingly lovely it is with its double lilac, very fragrant flowers. The evergreen *A. ledifolia*, sometimes blooming in early April, and like a pure white *indica*, is as trustworthy as it is good. Very

fresh and delicate is *A. Vaseyi* in a waxen pink and white, and this year *Rhododendron punctatum* (*minus*) in a cool blush, and very delightful on its shady bank amid creeping Ivy and unfolding Ferns, has been just in time to take up the tale where *R. racemosum* left off.

North Wales.

A. T. JOHNSON.

NOTES FROM GLASNEVIN

BY LADY MOORE.

THAT remarkable hardy bog plant, *LYSICHTUM CAMISCHATCENSE*, gives to the bog garden in the month of April a glow of very welcome colour. Its bold rich yellow Arum-like flowers, which are often 18 ins. in height, remain fresh for two or three weeks. The sheath or spathe then falls back, showing the long spadix covered with tiny cream-coloured flowers, the spiral arrangement being clearly seen. Later the leaves push through. Of a beautiful bright green marked with a darker shade, they are very large, about 3 ft. long and 1 ft. across. The large succulent roots go deep into the bog. It seeds freely here all round the parent plant. In North-west Canada it is called the Skunk Cabbage. It fills the marshes and stretches for miles along the lake shores.

The early-flowering *OURISIA MACROPHYLLA* is a native of New Zealand, where it grows in damp mountainous localities. Its evergreen leaves are pointed oval in shape, 3 ins. long, deeply veined, produced from creeping stems. The pink buds appear about the end of March; the flowers are white with yellow hairy centres and dark brown veining. They are three-quarters of an inch across, borne in whorls on strong dark stems which grow to a foot or more in height. A fine plant here grows on a rocky bank facing north and has spread into a thick tuft. The soil is half peat and half loam. It is well drained, but remains moist during the summer. This plant dislikes sun. It comes very freely from seed. *Ourisia coccinea* is often seen in gardens. Its bright scarlet tubular flowers make a great show, but for distinction and charm it cannot compare with *O. macrophylla*.

LATHREA CLANDESTINA is remarkable and interesting in that it is a parasite, growing on the roots of trees, its favourite hosts being the Willow and Poplar. A plant established on the roots of a deciduous Cypress has been recorded. It has thick, fleshy, scaly white rhizomes; its stems are nearly buried in the earth. The flower-buds are produced in thick spongy masses, which open into greyish violet-coloured flowers with a dark purple lip. They are 2 ins. long, erect and very numerous. The plant in this garden was established on the roots of a Willow on a grass bank beside the river. It is now (April 24) in full flower, and the effect is like that of a mass of purple Crocus. It evidently seeds freely, as it has extended 10 ft. on each side of the Willow beyond the original plant. It likes a damp soil. At Mt. Usher, Co. Wicklow, Mr. Walpole's well known garden, I have seen it a solid square yard of purple flowers, on the roots of a Willow beside a little stream, unshaded by grass—where one could see these curious supercilious-looking flowers to great advantage. It is common in hedge banks in the Pyrenees and in the South of France; it is also found in Belgium, Spain and Italy. It is much more attractive than our anemic English *Orthwort*, *L. Squamaria*.

THE ADMIRABLE WEEPING BROOM, *CYTISUS KEWENSIS*.

THE WHITE PORTUGAL BROOM, *CYTISUS ALBUS*.

THE HOLLYHOCK

Its uses in every style of garden, methods of propagation, and ways of avoiding and overcoming disease.

THOUGH the double Hollyhock of to-day is a different flower to the double varieties in vogue, say, in Parkinson's time, inasmuch as its beauty is greatly enhanced by a very noticeable ring of guard petals, yet everyone agrees in considering it an old-fashioned flower. It would be interesting to know just what it is that makes a flower seem old-fashioned. Is it perhaps a certain primness of growth and finish of flower such as were dear to the heart of the old florist? The symmetrical bush and regular flower of the double Peony, for instance, is eminently old-fashioned. With the more truly beautiful single Peonies, which possess more of grace and less of form, much of the old-fashioned feeling is lost. So is it with the Hollyhock. The stiff spires of the double sorts, with their individually perfect blossoms so regularly arranged on the spike, have a quaint artificiality which stamps them as old-fashioned; but the equally, if not more beautiful, single-flowered, fig-leaved and Allegheny strains are especially when well grown and bushy, not old-fashioned at all—are, in fact, as modern in feeling as their cousins, the Lavateras, Sidalceas and Mallows.

Ancient or modern, there is no garden larger than a backyard which might not well be adorned with double Hollyhocks, and the old or new style of the garden may equally be upheld by them according to their arrangement. If the setting is old-fashioned in character, the Hollyhocks should be planted in serried ranks even as they were planted centuries ago. Plant them, however, in bold and somewhat irregular groups at the back of the herbaceous border with one or, at most, two colours in a group, and they are, at once, as modern in conception as is the system of boldly grouping plants in balanced, but informal array.

There is a wide variety of plants suitable for the herbaceous border, but those who design such borders are well aware of many wants among herbaceous plants still very imperfectly filled, if filled at all. There is, for instance, small alternative to the use of Hollyhocks in the back row of the border. We have, it is true, golden perennial Sunflowers of sorts, Mulleins in creamy white and soft yellow and some of the tallest Delphiniums in shades of blue and purple, Tree Lupins again in white and soft yellow and then, without Hollyhocks, we are finished.

Very fortunate is it, then, that the Hollyhock has a wide range of colouring and that its shades are such that they harmonise not only with other shades of this flower, but with other hardy flowers, so that in a border with a wide colour range they may be employed throughout and so assist in emphasising the essential unity of the whole. The maroon shades may be used in combination with the salmon-pinks to make a striking group, or if employed in a section of the border where yellow-pink tones prevail, they provide a delightful foil to these. Crimson and soft yellow Hollyhocks and azure blue flowers of some sort—what a combination! or the crimsons may be Hollyhocks and some soft yellow foreground planting be introduced. Again, crimson and rose Hollyhocks may be used together satisfactorily in those sections of the border where mallow-pink is a feature; or, on occasion, the pure white may replace the crimson in the combination. If the single-flowered forms are used even more subtle combinations may be employed, since the flowers themselves usually contain a combination of shades.

Hollyhocks may be propagated from cuttings of the shoots produced at the base of the plant, and years ago, before the advent of the dread fungus, always were so propagated. Named

A CREAM-PINK SINGLE HOLLYHOCK.

varieties may still be purchased from Messrs. Vert, the firm who to-day carry on the Saffron Walden business started by the famous Chater; but most people are content to raise theirs from seed, or to buy plants so raised. If seeds in separate colours are procured from a reputable firm, they will be found to come true to colour and wonderfully close to type. They have, moreover, a vigour which vegetatively propagated stock cannot rival. This is no small merit, since height is one of the Hollyhock's principal attributes, and resistance to disease is vital.

The present is an excellent season at which to sow the seeds in drills in a cold frame or even outdoors. The ground should be moderately

rich without being gross—the Hollyhock is not a rank feeder like the Pentstemon. The seeds are large and not cheap to buy, so should be sown thinly. The plantlets should not be coddled, but should, when large enough, be carefully pricked out in nursery rows at least a foot apart. Given good culture, they should be large enough to be moved into their permanent stations this autumn.

Reference has been made to the Hollyhock fungus, or "rust," as it is sometimes called. This unquestionably is often transmitted with the seed, so that seed from infested plants should never be sown. Spraying with Bordeaux or Burgundy mixture is valuable, especially as a preventive; but the special powder offered by Messrs. Vert is easier to apply and certainly not less effective. Plants are like animals in this, that each race seems to obtain, with time, a certain immunity from, or resistance to, a particular disease. Certainly the Hollyhock disease is to-day an innocuous complaint compared to what it was years ago, when it practically drove the Hollyhock out of cultivation. It might before now have been stamped out had not it affected our wild Mallows Diseases which attack wildings are, of course, difficult of control. The Hollyhock is not, unless propagated, a long-lived plant—at least, old roots lose much of the stately port which is so much admired—so that batches of seedlings for replacement purposes should be raised at any rate every second year; but it is probably better to raise half the quantity each year so that casual gaps may be filled without trouble.

PRIMROSES

THE inspiring account of Mrs. Berkeley's splendid strain of coloured Primroses arouses a combination of the sentiments of encouragement and regret in the mind of a fellow worker among these inestimable spring flowers; encouragement, for the assurance, already well proved, of the sure reward of many years' careful selection, and regret that one cannot do a great deal more. For, unless one can be wisely content, as is the owner of the Spetchley Primroses, to grow all the colours together, one cannot repress the desire to take each good colouring separately and work along with it till one has got to the best in that particular colour, or to something so near the best that all the varying blooms shall be good in themselves and go well together. The sentiment of regret includes the fact that I have not four or five quite separate gardens, of which one would be on a good loam and one on chalk and one in naturally cool woodland; whereas my sole garden is on a dry, hungry sand, with a hundred feet of sand and rock under it and above any natural water; so that Primrose growing is a constant fight against natural conditions and a constant expense for yearly manuring. There are some charming forms that I cannot grow at all, the old double ones, white, pale yellow, pale lilac and crimson; they simply die out, for they are only contented in a good loam such as is also the delight of Auriculas. These too are denied me to my unending regret, for both to sight and scent, and indeed in all their ways, they are to me some of the most joy and thankfulness-giving flowers. I can never sufficiently praise and enjoy the adorable way in which the colour and texture of the flower surfaces work together to form their miracle of beauty and delight.

The large garden Cowslips are fine things of delicious scent, but they are dangerous to have in a garden with other Primroses. The Cowslip influence is so strong and carries so readily that it they are anywhere near it is difficult to keep the Primroses true. GERTRUDE JEKYLL.

SOME ALPINE PINKS

THE veriest tyro with a small rockery will usually cultivate a number of more or less suitable varieties of *Dianthus* upon it. Many of the sorts frequently seen upon such rockeries are mongrel forms owning probably a certain amount of Cheddar Pink "blood." The Cheddar Pink (*D. cæsius*) is assuredly an easy and worthy plant for the rock garden, though perhaps the form *D. c. arvensis*, much more compact in habit and shorter of stalk, will appeal more strongly to the real alpine enthusiast.

The limestone-loving *Dianthus alpinus* is not easily persuaded to give of its best in Britain; still, even as it grows here, it is a singularly beautiful plant with rich green, broad, blunted-ended foliage and flowers of such regularity and roundness as would suit the lover of florist's flowers. There are numerous varieties, but it is doubtful whether any excel in beauty the typical plant.

Dianthus callizonus is, many would say, even more beautiful than *D. alpinus*. It is lighter in colouring with a darker zone sprinkled with white spots. Both *D. D. alpinus* and *callizonus* and the hybrid between them (*D. cal-alpinus*) like abundant sunshine in well drained soil. The ravages of slugs and snails must be guarded against. The hybrid is roughly intermediate between the two species, which cross very readily.

Dianthus neglectus is also a sun-lover, but does not appreciate calcareous soil and succeeds best of all in the rocky cliff. This is a variable treasure, but at its best the cherry-red blossoms with a buff reverse are among the most vivid things in the June rock garden. *D. D. alpinus* and *callizonus* do best in the moraine, but the same cannot be said of *D. neglectus*, though it may be established there.

Dianthus sylvestris, so called as Farrer pithily puts it, "because it is never found in woods," should more properly be known as *D. inodorus*. It is a more variable plant than even *D. neglectus* with clear pink blossoms, sometimes round and smooth edged, anon starry and toothed. *Dianthus frigidus* of gardens is, according to Farrer, but a form of this species, but it is for garden purposes sufficiently distinct, with large blossoms on quite short stalks.

Dianthus superbus, with blue, deeply fringed flowers on rather weak foot-tall stems is a sub-alpine species which likes a western exposure. Its scent is truly delightful.

The Maiden Pink, *D. deltooides*, needs little description. It will seed itself and flourish almost anywhere—even in the gravel of the garden path. The best forms of this rather variable plant are, however, both beautiful and striking, and it flowers when many alpinists are over. This is interesting as a native species. Botanically *D. graniticus* is quite distinct from this, but from a garden

standpoint they are much alike. The cluster-headed Pinks, though many of them true alpinists, are hardly beautiful. They resemble too much a singularly ill-grown Sweet William. *D. Carthusianorum* may be taken as the type; it has several varieties. Then there are *D. cruentus*, even taller and weedier, but with paler crimson flowers; *D. atrorubens*, dwarfier in habit and with larger and more showy flower-heads, and a host more, all inferior to a good strain of the Maiden Pink, for instance.

Three tiny forms for the moraine shall conclude this brief note. These are *D. D. microlepis* (*pumilus*), *Freyui* and *glacialis*. The two former

can hardly be separated, as they are much alike and both variable. In both the flowers are carried quite close to the spreading, tufted, rather glaucous foliage. *D. glacialis* differs in having rather larger tufts of greener foliage with relatively smaller blossoms.

Much of the want of vigour often attributed to the choicer alpine Pinks has come about by over division. They should, whenever possible, be raised from seed, but in saving one's own seed steps must usually be taken to prevent cross-pollination if the different species are required true. Collected seed of many sorts is cheap and, of course, reliable.

WALLFLOWERS IN THE SPRING GARDEN

BY GERTRUDE JEKYLE, V.M.H.

THOSE who live on chalky soils should remember that they would do well to give special attention to the Wallflower and all its tribe. Plants of the order Cruciferae will thrive in any good

Those who are on a suitable soil and who are able to give a separate place to a garden of spring flowers, will have the opportunity of growing Wallflowers to the very best advantage.

They are splendid in long drifts as a groundwork to Tulips of accompanying or contrasting colours—Tulips of scarlet and deep orange with the blood-red colourings, pink Tulips with ivory white, leading to white Tulips rising from sheets of Forget-me-not and Aubrietia. Then tall yellow Wallflowers, largely intergrouped with the tall *Doronicum*, with yellow Tulips in front and a bold backing of the plaited-leaved *Veratrum* and the larger fern-like leaves of Sweet Cicely; and these running into clumps of Solomon's Seal, with corresponding dwarf yellow Wallflowers to the front. There are now splendid colourings of rich, deep orange that tone grandly into the mahogany browns, and form the finest possible setting for Tulips of near colours.

Many as are the good new forms of the sweet and welcome Wallflower, there is one class of colouring that has as yet escaped the bettering of which it is undoubtedly capable at the hands of the selecting seed grower. The old purple Wallflower is already a valuable plant, but the redder forms that have evidently been derived from it seem to have exclusively absorbed the energies of the grower, to the entire neglect of the really good cool purple that is so badly wanted—a purple inclining towards blue rather than towards red. We want such a purple to go with Tulips *Ergaste* and *Rev. Ewbank* and the old tall double, *Bleu Celeste*. It would also be a lovely thing in combination with white Tulips

and double *Narcissus poeticus*, with a ground covering of *Aubrietia* and white *Primroses*. Any influential seed house that would promote the growing of such a good purple Wallflower would be doing a signal service to horticulture and could hardly fail of finding the just reward that awaits the production of something that is really wanted.

SOME TYPICAL WALLFLOWERS.

oam, but do specially well on chalk and are never happy or really vigorous in places where the soil is light or sandy. It is easy to remember this by thinking of the natural habitat of the wild Wallflower; the joints and crevices in the masonry of old walls and ancient ruined buildings, where it is most usually found, the roots feeding on the relics of the old mortar.

THE GREAT SPRING SHOW AT CHELSEA

As Seen by THE GARDEN'S Special Staff of Disinterested Correspondents.

GARDENING in its different aspects is a profession, a science, an art and a hobby. Results, good or bad, every gardener obtains, and results rather than events absorb the average gardener's interest. Events in the world of horticulture may be summed up in two words—flower shows—and the average amateur gardener or, as we should prefer to call him, the enthusiastic garden hobbyist takes little interest in ordinary flower shows. If he subscribes to and takes an interest in the local horticultural society, he usually does so rather as a duty to his neighbours than for any particular pleasure the show affords him.

The fortnightly meetings of the Royal Horticultural Society with their ever-flowing stream of new introductions probably interest him—directly if he live within easy reach of London, indirectly through the columns of *THE GARDEN* if his work lie further away. The summer shows usually held hitherto at Holland House he has regarded as glorified—much glorified—"fortnightlies." "Chelsea," however, as the spring show is universally, one had almost written affectionately, called, is *the* event of the gardening year. It is in many ways entirely different to the fortnightly meetings. There are, of course, plants put up for award at Chelsea, but they form but a very small part of the attraction of the show.

By far the greater number of visitors to the Hospital Gardens are there, primarily at all events, to gather ideas as to garden arrangement. It may be urged that if this be so it is rather remarkable that the garden designs displayed in their special tent are not more largely visited.

For this, however, there are at least two reasons. In the first place, not everyone in search of ideas as to garden arrangement wants his garden re-designed. He may be in search of colour effect for a particular border or he may think, for instance, of introducing or adding a rock garden. In neither case will he feel the want of a comprehensive garden plan. Secondly, not everyone has the ability to visualise a garden even from the best drawn plan. Thus it comes about that while the garden designs are comparatively neglected, the various model gardens, built of the proper materials and aglow with pleasing colour, are so thronged that it is hardly possible to get that comprehensive view which alone can do them justice.

The area devoted to such model gardens, for though to a large scale—some even "life size"—models they are, is this year larger than ever, so that one wonders where all the business can spring from that can justify such great expenditure. They undoubtedly get more numerous and more ornate season by season.

The various features of the show will be found reported upon very fully and candidly in the following reports, but there is one other matter to which special attention may well be drawn. Several extraordinarily fine

than will comfortably keep them frost free. They will in winter be better in a pit or frame with heat available than in a greenhouse.

MODEL GARDENS.

The spectacular outdoor exhibits at Chelsea have hitherto resolved themselves into two classes—gardens formally treated and rock gardens. No such arbitrary division is possible this year. The rock gardens are there as usual, and a very good and representative lot they are, but the remaining exhibits represent almost every style of gardening and sometimes two or three styles merged into one exhibit.

A consistent exhibitor at Chelsea is Mr. Jones of the Horsecombe Quarries, but beyond question he has on this occasion surpassed himself. The walling is everywhere carried out, as usual, in the narrow-coursed Horsecombe stone. The garden is secluded from the Elm Tree Avenue by a wall surmounted with thatch "Zummerzettshire"-wise, and a thatched gateway gives access to the garden. Within the gateway a trickle of water is bridged, of which more anon, and then two steps up lead to a quaint but restful little formal garden of which the walls rise about 15ins. above grass level. Within them a narrow (18in.) border filled very naturally with masses of spring flowers gives a touch of harmonious colour. On the left hand a 2ft. wide border on the higher ground level with the wall top increases the effect. The old-fashioned lawn behind is adorned with an Apple tree of some size and age. Other Apple trees and Silver Birches serve to frame the garden. Fitting admirably into the general scheme, a Tudor style garden house and pump house combined (complete with pump) emphasises the note struck elsewhere. A trickle of water starts from a spring in the near left-hand corner as one enters

SUTTON'S GIANT STREPTOCARPUS.

the garden and, running round two sides of the garden, ends in a little pool. The main vista from the entrance gate crosses, beyond the garden-house, a small sunk Iris garden to end in a really beautiful wrought-iron screen of Italian workmanship. A cross vista through the Iris garden terminates at one end in a well-head, and at the other in a very beautiful and imposing sundial. Beyond these a stone seat represents all the garden furniture included in the scheme, which is as it should be.

Messrs. Bunyard of Maidstone have a really charming Iris garden, which, with Messrs. Macdonald's garden of Grasses, should be the Mecca of those whose eyes have become tired of kaleidoscopic colour. The garden is arranged on two levels, of which the outer and higher is planted with Bearded Irises and other plants, and the

exhibits draw attention to the value of well grown hardy and half-hardy annuals for conservatory and house decoration in springtime. Annuals are still insufficiently appreciated not only for this purpose—though for that alone they are invaluable—but also for the open border in summer and autumn.

At the Show their merits for decorative purposes may readily be compared with those of more orthodox greenhouse plants, and most people will find them little, if any, inferior. When it comes to "practical politics," however, the difference in cost of production is really startling. The hardy annuals may well be accommodated in cold frames in winter, while even the gorgeous *Calceolarias* need no more heat

lower, taking the form of a circular sunk garden, entirely with Irises; Bearded Irises filling all the beds except a small one around the central sundial, which is planted with Spanish Irises. Simple in design and feeling, but admirably proportioned, this garden gains much by the natural spacing of the plants, a point too often neglected at flower shows.

With a rectangular space to dispose of, such as many readers of THE GARDEN have to make shift with, Messrs. Wallace have contrived an exhibit of purely informal planting of which it is possible to speak in terms of the highest praise. From view points only a few paces apart it is possible in this exhibit to get two pictures, each perfect in its way but quite dissimilar, the one giving a glimpse through a Rhododendron dell with two wonderful specimen Rhododendrons as part of the picture, and the other with woodland shade and water, waterside Primulas and Mollis Azaleas in glorious and brilliant hues all contributing to a beautiful picture.

Messrs. Carters have a purely formal garden of which the outer borders are filled with Tulips, Anemones and Rhododendrons. Some of the pink-toned Tulips, by the way, hardly seem to the writer to tone one with another. A little sunk garden in the centre serves mainly to display an amusing novelty—a floral clock which certainly goes and is said to keep Greenwich time! It is not necessary to criticise such an exhibit from a practical point of view or one might draw attention to the turf running to the foot of the retaining walls as difficult and expensive to maintain. Substitute, however, a floral sundial for the clock and the idea would be practicable enough.

On the other side and at the bottom of the Elm Tree Avenue Mr. Klinkert of Richmond has a formal garden entirely of topiary. The garden is intersected by avenues edged with the soft grey and mauve of *Nepeta Mussinii*, and the views down these are pleasing enough, but it is as a topiary exhibit that it should really be considered, and from this point of view it is possible to speak of it with untinged praise.

The value of Polyantha Roses for bedding cannot be over-emphasised, and it is a real pleasure to see these bedded out in Messrs. Cheal's sunk garden. Among the Roses is a narrow Lily tank,

so narrow at its ends as to be practically a rill. One minor point of criticism here. Like Messrs. Carter, the Crawley firm run their turf to the foot of the retaining wall, which is hardly practical.

only for one. The consequence is that despite very carefully and well arranged stone the informal rock, shrub and water garden, because of the formal side hedges, looks somewhat suburban

A RHODODENDRON GLADE IN MESSRS. WALLACE'S EXHIBIT.

and 'pretty-pretty.' The little sunk blue garden, however, strikes a more restful note. The paved paths and pergolas leading up to these features are well arranged and particularly pleasing. Messrs. Gaze include a dry tennis court and a garden house in their exhibit.

Messrs. R. Neal and Sons of Wandsworth Common have also attempted an ambitious programme in a limited space. A miniature canal spanned by a substantial stone foot bridge leads to a summer-house absurdly inadequate to the approach. In front Messrs. Neal display a suitably arranged rockery bank.

Messrs. R. Neal and Sons of Wandsworth Common have also attempted an ambitious programme in a limited space. A miniature canal spanned by a substantial stone foot bridge leads to a summer-house absurdly inadequate to the approach. In front Messrs. Neal display a suitably arranged rockery bank.

The En-tout-Cas Company display a model of their famous hard court in an agreeable setting. The court and a pleasing surround fill the centre of the exhibits beyond which a quaint little formal garden leads to a rather nice thatched wooden summer-house. *Nemesias* and *Azaleas* provide most of the colour, and white *Stocks* and *Mignonette* form an effective bank at the entrance.

Messrs. Macdonald of Harpenden have a formal garden consisting entirely of their magnificent turf and various ornamental Grasses. This is a cool and really beautiful exhibit which no visitor should miss.

Messrs. John Waterer, Sons and Crisp have an exhibit of which the principal feature is an oval sunk garden bedded with rose Tulips and *Nepeta Mussinii*. The surround to this consists almost entirely of dwarf plants of Pink Pearl *Rhododendron*. Well arranged borders of hardy shrubs and some excellent topiary complete the exhibit, which would have been improved if rectangular paving had been employed instead of "crazy."

Messrs. Kent and Brydon have a quite successful rock and water garden, marred only by the obviously rectangular outline of the space utilised. The entrance is contrived through pleasing banks of *Rhododendrons* and *Azaleas*.

Mr. Herbert Brook has an exhibit showing the practical application of stone to garden making.

A WEST COUNTRY GARDEN AS CONCEIVED BY MR. JONES.

ROCK GARDENS

Where so much and such diverse excellence is to be seen it is difficult to wield a critical pen. There is this year no rock garden which anyone need be ashamed to own. Most of them would, indeed, grace any garden.

Of Mr. John Wood's exhibit it may be said at once that it is, at any rate, the equal of anything he has built at Chelsea hitherto, and that is high praise. His scheme represents, as usual, a stretch of moorland, idealised, it is true, but still moorland. His levels and water are, as always, beautifully managed, and the planting, though by no means skimpy, is admirably restrained. His use of a huge number of splendid clumps of *Gentianella* should be an object lesson to many amateur constructors.

Captain Symons-Jenne also has a "moorland" exhibit, quite well done and more effectively planted than has been his custom at these shows hitherto.

In a more "domesticated" vein, and incidentally a more practical one, since "moorland" is not cheap to maintain, Messrs. G. G. Whitelegg and Co. have a refreshing bit of work displaying fine and well arranged masses of *Phlox canadensis*, *P. setacea* G. F. Wilson and *P. s. Vivid*, with *Aubrietias*, *Saxifrages*, *Sun Roses*, *Æthionemas*, *Gentianellas* and other suitable plants. The waterfall and deep crannied pool are exceedingly well done.

In a rather different but still practical gardening style, Messrs. Pulham's rock garden is sufficiently effective, though it lacks those beautiful ravine glimpses which give so much joy. Among a lot of excellent plants one noted *Salix alpina* (the

Alpine Willow); also a nice patch of *Trilliums*, albeit the ledge on which they were placed looked over-dry for the plants in question.

Messrs. Tucker of Oxford go in rather for the practical than the spectacular. The hardy *Maidenhairs* (*Adiantum peslatum*) by the inevitable waterfall are very beautiful. Of the admirable alpines, including many moraine plants, we shall have more to say in our next issue. One small criticism! Why plant *Silene alpestris* in the moraine?

Messrs. Hobsons of Nottingham have a rockery in a material widely different from the others, large blocks of weathered sandstone being employed. In the space allotted them little effect of depth is possible. Visitors can, by the aid of this exhibit, easily compare the advantages and disadvantages of sandstone and the moorland limestone outcrop now so generally used.

Mr. Clarence Elliott has a little rock garden mainly consisting of a low bank which would be excellent for alpine culture. Of his plants we shall have something to say in next week's issue.

IRISES

The bearded Irises have lately taken two Continents by storm, and now, both in Europe and North America, they form one of the most important groups of all hardy garden plants. It might almost be said that the Iris has grown in popularity hand in hand with the popularity of gardening itself, but while appreciating the magnificent inheritance of remarkable flowers brought into being by the efforts of Mr. Bliss, Mr. Dykes, Sir Arthur Hort, M. Denis and Mr. Yeld, we must not overlook the value of the pioneer work done by

the late Sir Michael Foster and the late M. Henri de Vilmorin. These two enthusiastic breeders were at work as far back as the seventies of last century, the former collecting a great variety of plants from Central Asia and Asia Minor, from which many of his seedlings were derived. M. Vilmorin's early attempts, on the other hand, were mainly crosses of *I. I. asiatica*, *trojana* and *cyprina*. This, however, is not the place to trace the history of these delightful flowers now spread for our captivation, rather let us note a few of the outstanding varieties. All lovers of the bearded Iris will gravitate to Messrs. Wallace and Co.'s collection. The famous Tunbridge Wells firm have brought up one of the most brilliant collections of Irises ever seen at Chelsea, practically every flower is a gem, and they show at a glance the enormous advance made in recent years by the best known raisers of the day. One is pleased to note the much discussed American variety, *Lent A. Williamson*, said to be the finest hybrid yet raised in the United States. A noble flower of fine proportions it is; but it is in hard company, surrounded by the gems of British and French production, and we shall hardly offend our American friends if we state that it is not the best Iris of the lot. Close by are *Prospero*, a Yeld hybrid of outstanding merit; *Lady Foster*, one of the finest of those raised by the late Sir Michael; the stately *Lord of June*, a glorious study in lavender and violet; and *Crusader*, a near approach to real blue. Every one will notice the giant-flowered *Magnifica*, a Vilmorin introduction of great merit, but one of the beauties of the collection is much more modest in size and must be sought out, *Suzan Bliss* by name, and the nearest approach to pink we have yet seen in this genus. It is really a delicate

A GLIMPSE IN MESSRS. WHITELEGG'S ROCK GARDEN

ONE OF SEVERAL PICTURES IN MR. JOHN WOOD'S EXHIBIT.

lavender pink, but dainty and sweet to a degree. Phyllis Bliss, its parent, is alongside, but the colour scheme is not so delicate nor the flower quite so refined. Here, too, can be seen Dominion, Morwell, Mrs. Cowley, Sweet Lavender, Dmity, Blue Lagoon and Cretonne, a cluster of variously coloured Bliss seedlings of much merit. From the same source one can hardly omit the lovely little Sudan, of dwarf growth and bright colouring, or Dusky Maid in its quiet gown of coppery pink. Indeed, to launch out on a description of the Irises raised by Mr. Bliss alone would be something like a disquisition on the genus, and yet would leave out such giants of the race given to us by the Vilmorins, the Yelds, the Horts and the Dykeses. The gist of the whole matter is that no visitor must leave Chelsea without an exhaustive examination of Wallace's Irises.

But other Iris exhibits must also be explored. There is the unique stand of Regelia and Regelio-Cyclus Irises shown by Messrs. Whitelegg and Co., of Chislehurst, of which we have never seen finer samples. Nor have we ever seen such a lavish display of that excellent garden plant of recent introduction—Iris Hoogiana. This is probably the most beautiful and certainly the easiest of cultivation of the Regelia section and quite moderate in price. Korola, and Korolkowi Leichtliniana are members of the same section, the former raised by Mr. Dykes, and a very striking flower. Some of Messrs. Whitelegg's new Regelio-Cyclus hybrids are specially worthy of note, but it is rather difficult to get words to catch a true description of the wonderful colours depicted in these flowers. Isolda has a ground colour of old gold heavily veined and stippled with brown, Camilla, a handsome novelty, has standards of mauvy-purple and falls of cream very densely flushed and lined dark velvety purple. Thalia, again, is cream, beautifully reticulated brown, and Osiris, also new, with white standards suffused with a purple flush and netted purple black, falls white, veined deepest purple, is conspicuous. Freya, Vera and Hebe are all new introductions, while among the older ones one would specially note for their beauty Charon, Psyche and Una.

Mr. Amos Perry has, as usual, a most varied table of Irises chosen from the tall bearded, the intermediate, and the Regelio-Cyclus sections. Here, too, is a fine mass of Iris Susiana, ever attractive by reason of its strange and sombre garb. Among the Regelio-Cyclus specimens, particularly pretty are Pollux, Orestes, Jocaste and Mars. The species Iris Vaga is not often exhibited and will strike visitors as being something quite out of the common. Its dainty dress is a "Liberty" fabric in bronze, purple and lavender.

PERPETUAL-FLOWERING CARNATIONS

The whole of the north end of No. 1 Tent is occupied with one of the most remarkable displays of these popular flowers, arranged by Messrs. Allwood Brothers, Hayward's Heath. In this instance this firm have surpassed themselves in the way in which they have disposed the well grown blooms of high quality. Doulton ware, in great variety and highly artistic, is largely used, with the result that the exhibit is quite unique. This wonderful display is sure to be one of the chief attractions of this great Show, and deservedly so. The groundwork and background of black velvet accentuate the beauty of individual vases of blossoms, and handsome Palms and cut foliage add materially to the general effect. Our attention is particularly attracted to Maine Sunshine, regarded as the best yellow Carnation; Edward Allwood, scarlet; Jessie Allwood, a beauti-

ful yellow Malmaison; Wivelsfield Apricot, a free-flowering apricot—quite a new one in Perpetual Carnations; Wivelsfield White, a chaste white sort; Triumph, a good deep, rich crimson; Benora, white fancy, streaked red; Marion Wilson,

these two latter are the two largest Perpetual Carnations in cultivation.

Good quality always characterises the blooms set up by Messrs. K. Luxford and Co., Harlow, Essex. These exhibitors, like several others, suffered for

MESSRS. BUNYARD'S IRIS GARDEN.

yellow streaked red; Mary Allwood, a notable cherry salmon-coloured flower of fine quality; Eastern Maid, a heliotrope flaked sort of considerable charm, and the new salmon-cerise fragrant Wivelsfield Pink.

An exhibit of Carnations which is sure to attract every visitor's attention is that arranged by Mr. C. Engelmann, Saffron Walden, Essex. This display is arranged in No. 1 tent and is of circular form, towering up to a considerable height, only a few feet below the canvas roof of the tent. There are no fewer than six hundred dozen blooms in this fine exhibit, which comprises novelties and standard sorts, all in the pink of condition. The blooms are remarkably fresh and very bright and clean. We could not fail to notice the following sorts: Tarzan, a grand scarlet; Cream Saffron, a lovely cream sport from Saffron—a new colour; Circe, mauve flaked; Crystal White, one of the purest white sorts. There is a very fine vase of Laddie, a beautiful flesh pink sort. Nigger, a new rich crimson, is very fine. One of the coming scarlet sorts is Scarlet Iona—a sport from the latter. A new variety to be distributed next year is Surprise, a grand, soft salmon pink sort of great promise. Thor, a brilliant scarlet flower that attracts one to it is also noteworthy.

At the eastern end of No. 2 tent an attractive display of Carnations, set up in artistic fashion by Messrs. Stuart Low and Co., Enfield, calls for notice. Here are to be seen a large number of vases, stands, bowls and other receptacles, arranged on a table space in artistic fashion, with abundant foliage and dainty ferns, etc., to add to the general effect. Baskets suspended on iron standards above the group add in no mean degree to the display. We have a special preference for the following sorts: White Pearl, the disease-resisting white, of chaste character, very sweetly scented; Eileen Low, one of the best salmon pink sorts; Reginald Cory, gorgeou cerise; such choice perpetual Malmaisons as Hon. Charlotte Knollys, colour cherry red; and Miracle, cerise—

want of space, and, consequently, could not make the display they desired. They have done well, however, and are exhibiting about four dozen bronzed vases of artistic form, filled with blooms of excellent form and colour and of good quality. For effect they have added foliage plants. The better varieties are: White Benora, a beautiful white sport from the well known variety Benora; Mrs. C. W. Ward, a rich pink sort and the best of its type; Aviator, a full rich scarlet; Enchantress Supreme, still one of the best flesh pink sorts; and Coquette, a deep mauve with cerise splash.

Messrs. Bees, Limited, Liverpool, have a small table group of Carnations, perpetual and Malmaison, all interesting. Of the latter the Hon. Charlotte Knollys is to be seen in grand condition. Of the perpetual sorts, Mary Allwood, White Enchantress, Wivelsfield Claret (a rich claret) and Benora are worth noting.

Messrs. William Cutbush and Son, Barnet, Herts, as usual, stage a dainty exhibit—part of a large and comprehensive display—of Carnations. The flowers are displayed in white baskets, stands, etc., in pleasing fashion, and represent standard sorts of the perpetual and Malmaison types of the flower. The groundwork of fine foliage plants adds materially to the general effect. Of the better sorts are Renown, pink; White Wonder, white; Carola, rich deep crimson; Scarlet Carola, scarlet sport from the former; Sunstar, yellow; Circe, deep mauve; and Baroness de Bruant, deep pink. Each of these sorts call for special notice.

BORDER CARNATIONS AND PINKS

Border Carnations are represented by exhibits from Mr. James Douglas and Mr. Horace Lakeman. Mr. Douglas' flowers are, as usual, excellent. He has several remarkable new sorts on show. Of these the outstanding is Kelso, a magnificent

flower of apricot buff body colour streaked with purple grey. Others are Lombard Hills, pale canary yellow, streaked lavender grey; Dr. Connors, citron yellow flushed pink and striped scarlet; Viceroy, citron yellow, so heavily striped and margin deep wine-red that this becomes the main colour of the flower; The Cadi, a study in brown shades, being actually rose-madder, striped orange and purple; and Highland Mary, citron yellow, striped bright rose. Not new, but seldom seen on the show bench is Marajah, palest blush striped and wire-edged with crimson purple. The beautiful and fragrant Cloves are not neglected. One notes excellent vases of Crystal Clove, Salmon Clove and Claret Clove. Mr. Lakeman has excellent flowers of such standard varieties as Fair Ellen, My Clove, Lieutenant Shackleton and The King.

Border Pinks are mainly, if not entirely, represented by the *Herbertii* strain of Mr. C. H. Herbert and the *Allwoodii* of the brothers Allwood. Mr. Herbert has most of the fine varieties previously exhibited at Chelsea and some really excellent new sorts. Very noteworthy are Fire King, a full double flower of vermilion scarlet colouring; Red Indian, of almost Indian red colour; Prince of Wales, pale salmon pink, a full flower; Mrs. C. H. Herbert, in the way of the beautiful Model, but larger, a shade more salmony in hue and scarcely so perfect in form; and Juno, a very large crimson sort. Of the older varieties Mrs. G. Walker, Victory, Ruby, May Queen and the immaculate Model may be noted. A sin. pot of the purple The Imp was shown with thirty-nine flower stems, showing conclusively the free-flowering character of the strain.

The *Allwoodii* are very tastefully displayed in stone-edged beds on either flank of Messrs. Allwood's

big Carnation exhibit, also in a large circular bed displaying specimen plants. For bedding one would select Joan, rose with a deeper eye; and Vera, salmon-blush, as two of the best.

ROSES

The exhibitors of Roses are almost as deserving of the visitors' sympathy as are those who arranged the gorgeous collections of Tulips, for they have suffered nearly as greatly from the intense heat of the tents. The rosebud of the morning became a full blown rose long before midday, and in some cases did not wait for the morrow before dying. But, nevertheless, there are many beautiful blooms to be seen, particularly on the pot plants shown by Messrs. Paul of Cheshunt, Messrs. William Cutbush, and Messrs. Paul and Son.

It is the free-flowering climbing Roses that are the most effective, and of these the veritable rose garden that Messrs. Cutbush have made solely with Polyantha Roses is quite delightful. Excellent examples are also to be seen in the group of Mr. William Paul, who includes his gorgeous Paul's Scarlet Climber next to masses of the vigorous Tausendschön. American Pillar and Delight are also admirable here. In the group by Messrs. Paul and Son such Ramblers as Paradise, Ethel, Lady Godiva and The Premier are equally charming. The last named received an award at Regent's Park not long ago, and it is now fully evident that the award was justified, for it is a charming blush pink cluster Rose. Another recently arrived variety, Coral Cluster, is represented in quantity.

Pink Delight, as shown by Messrs. Laxton Brothers, with the Strawberries which tempt

one almost past endurance, is a truly delightful little single Polyantha Rose.

Many good Roses are included by Mr. Charles Turner with his fragrant Lilies; while Messrs. Frank Cant and Co. content themselves almost solely with quite a collection of new varieties, all shown in quantity, as though to illustrate how freely they bloom. Captain F. S. Harvey Cant is a fine pink Hybrid Tea variety. Mrs. F. S. Harvey Cant is a very large blush with a centre reminiscent of the old Souvenir de la Malmaison. Mrs. Alfred West, another large Hybrid Tea, is of a deep but showy pink shade of colour; while Mrs. E. Claxton is another promising pink Hybrid Tea Rose. Babs is evidently a garden Rose—the blooms are fully open early in the morning and show a decided "eye"; the colour seems to be a pale orange fawn.

Cut blooms are also shown by Mr. George Prince, who has charming vases of the dainty Madame Butterfly, Richmond, Sumburst and Melody. The two last named, as shown, are very much alike, but no one need confuse Madame Butterfly with Ophelia, a variety which some have said it is too much like.

Ophelia is shown in great beauty by Mr. Elisha J. Hicks, who also has large stands of Sumburst, another graceful variety which is popular with exhibitors in the decorative classes at Rose shows. Molly S. Crawford and an almost bewildering variety of Climbers assist in making a splendid display.

Mrs. Henry Morse is shown in great beauty as dwarf plants and cut blooms by several growers, and in Mr. Paul's group there are quite good standards, so we may safely conclude that this comparatively new pink sort is a good general

THE NEW PERPETUAL CARNATION WIVELSFIELD PINK.

A NOVEL-COLOURED BORDER CARNATION, KELSO.

utility Rose. Los Angeles, which stood the heat so well in many gardens last year, is also to be seen in excellent form; while the new Hybrid Tea Premier is also good. Of the other sorts, Florence, a new pink Hybrid Tea, and the old Prince de Bulgarie are represented by perfect blooms.

A number of the more recent certificated varieties are to be seen in an excellent collection of Roses by Messrs. B. R. Cant and Sons. These include such valuable sorts as Padre, Constance Cassoon, Covent Garden, Mrs. Oakley Fisher and the rich golden yellow Sovereign. These have all been shown in great beauty on a number of occasions during the spring, thus abundantly showing that most of the present day Roses which receive awards are general utility Roses, and as valuable for forcing for early spring decoration as for the outdoor garden.

STOVE AND GREENHOUSE PLANTS

Seldom, if ever before, have Messrs. Sutton and Sons made a display so large and comprehensive as that to be seen in the present instance. There are no fewer than twelve large groups comprising this exhibit, which is to be seen at the south-west corner of the first tent approached from the Embankment entrance. Here are to be seen hybrid Schizanthus in wonderful variety and beautiful forms, Clarkia Double Salmon, Primula obconica Salmon Queen and P. o. Scarlet Emperor, a reddish-coloured variety of great promise. Herbaceous Calceolarias, as usual, are

is arranged on the floor and is neatly finished with Ferns.

A table group of the choicer foliage plants and Cacti from Mr. H. N. Ellison, West Bromwich, is worthy of inspection. The Cacti as shown give one a capital idea of how the nucleus of a collection of these quaint plants could be easily formed. Noteworthy foliage plants are Davallia epiphylla, D. tenuifolia Veitchii, D. robusta, Cibotium Schiedeii, Platycerium Veitchii, Gymnogramme Pearcei robusta, Phoenix Robileni and Nephrolepis Mayii are just a few of the beautiful plants in this collection.

A kind of triangular group of show Pelargoniums is set up by Mr. Aubrey F. Wootten, K.C., Downs Road, Epsom (gardener, Walter Lamson). The plants are in the pink of condition and are freely flowered. We have seldom seen plants in more satisfactory condition. They reflect great credit on the grower. Some of the flowers are exceptionally large and striking, and the group edged with Maidenhair Ferns leaves nothing to be desired.

A quite unique display of Hydrangeas in the form of a circular group is that made by Mr. H. J. Jones, Ryecroft Nursery, Lewisham. Some of the blue and mauve-blue colours of the flowers are most noteworthy, while the white sorts and those of pink and kindred tones of colour are quite charming. Noteworthy pink sorts are Etincelant (lovely), Professor de Bois and Le Marne (magnificent). The blue-flowered are particularly striking, such sorts as Viscounte de Villebrugh and Mons. Ghys (mauve-blue) helping in charming fashion to make a very noteworthy

ificent series of mounds of Cineraria grandiflora, superb Gloxinias, striking herbaceous Calceolarias, fine Coleuses, Sweet Peas arranged in quaint Japanese baskets, Spanish Irises in variety, and a charming strain of Brompton Stocks, all well grown and Petunia Queen of Roses. This magnificent central group was beautifully finished with an edging of grass—a wonderful achievement—Pterises and a band of Ageratum.

Cinerarias, including stellata and cactus-flowering types, as well as their more gorgeous rival the grandiflora type, are represented in a group in No. 1 tent by Messrs. Webb and Sons, Stourbridge. These plants are quite good, as are also this firm's new giant hybrid Schizanthus. Rhodanthe maculatum is also shown. A pretty series of their superb herbaceous Calceolarias also call for notice. The group as a whole is quite pleasing.

Cinerarias in charming variety are shown by Messrs. Storrie and Storrie, Glencarse, Perthshire, in a large oval group at the south entrance to No. 1 tent. Here are to be found all types of the flower in pleasing variety and in interesting form. A notable feature is this firm's new Excelsior sun-proof scarlet strain of the grandiflora type. Grandiflora Winter Queen is a beautiful blue-edged sort. The stellata forms are wonderfully well shown, the colours being very distinct and pleasing.

An interesting feature of Messrs. Dobbie and Co.'s exhibit is a collection of dwarf, densely flowered Schizanthus and a fine Stock named Snowdrift, a cross between a Brompton and Ten Week Stock, very fine.

Much credit is due to Messrs. John Peed and Son, West Norwood, S.E., for the handsome large group of miscellaneous stove and greenhouse plants shown by them in No. 1 tent. This exhibit comprises such plants as Caladiums, Hippeastrums, Streptocarpuses, Verbenas, Hydrangeas, etc. The Caladiums are much smaller than usual, but they represent a quite large variety of the better sorts, fairly well coloured. The Hippeastrums are attractive, so too are the other plants. Palms as a background and Ferns and Moss as an edging in front make this display worthy of inspection.

A fine table group of the new Dracæna Deremensis Bausei is shown by Messrs. L. R. Russell, Limited. It is a striking plant and will grow satisfactorily in a moderate temperature. The foliage is bright green striped white down the centre of each leaf.

A splendid lot of Hippeastrums is shown by Lieutenant-Colonel Sir George Holford, Westonbirt, Tetbury, Glos., arranged on a table at the north-western end of No. 2 tent. Here are to be seen plants in superb condition, both form and colour being all that could be well desired. We were much struck with the fine quality of Chameleon, rich crimson; Harvest Moon, white ground, tinted rosy crimson; Rose Enchantress, a lovely rose; Maebeth, a monster crimson; Hymen, glowing crimson scarlet; Red Star, crimson, tinted rose; Hourii, white, slightly tinted rose, are just a few of the gems of this really exceedingly fine collection.

Messrs. L. R. Russell, Limited, also exhibit a grand bank of handsome Caladiums and other gorgeous stove and greenhouse plants, arranged in noble fashion and impressively. Three good Caladiums are Rising Sun, crimson, with dull green edging and spotted with deep crimson splashes; Mrs. L. R. Russell, one of the finest rich crimson and green, and William Rappard, another pale rosy crimson and green sort. Flora Russell, a deep crimson, is still one of the finest Caladiums. A plant worthy of special mention is Medinilla magnifica, seldom seen in flower in this country.

Hydrangeas in variety are shown in the large group of Messrs. W. Cutbush and Co.

Zonal Pelargoniums are shown in a few dozen excellent bunches by the Chalk Hill Nurseries, Reading, and these represent the better sorts.

A CORNER OF MESSRS. SUTTON'S GIANT EXHIBIT.

well shown by this firm, as are Cineraria stellata, in which the magenta colours are practically eliminated. Lobelia tenuiflora is finely shown.

A wonderfully fine group for a private grower is that which is set up by Baron Bruno Schröder, of Englefield Green, Surrey. In this beautiful group are to be seen grand examples of Schizanthus. Individual plants exemplifying the highest cultural skill are finely displayed, both form and colour being excellent. The plants have retained their foliage in most unusual fashion. Herbaceous Calceolarias, Streptocarpuses and Hydrangeas combine to make an interesting exhibit. The group

exhibit. Graceful Palms relieve the picture, and beautiful Ferns give a charming finish.

One of the largest and most attractive displays in the whole of this great Show is that made by Messrs. Jas. Carter and Co., Raynes Park, S.W. They have in this instance excelled themselves. This exhibit is disposed in No. 1 tent and consists of four circular groups of cactus and stellata forms of the Cineraria, edged with Brompton Stocks and Ferns. These four groups enclose a huge group of freely flowered plants, such as Schizanthuses, Spurred Aquilegias, grand examples of the Streptocarpus in fine form, colour and condition, a magni-

Dwarf Japanese trees in great variety and in many interesting forms are to be seen in the table group in No. 2 tent of the Yokohama Nursery Company, Limited, St. Albans, Herts. Ancient trees, said to be 150 years old, are in excellent form and condition and are a source of endless pleasure.

Zonal Pelargoniums in single, semi-double and double forms are well shown by Mr. R. J. Case, Taunton. Striking single sorts are Mrs. R. J. Case, Somerset Lad (salmon) and F. W. Penny (scarlet).

A capital lot of Zonal Pelargoniums are shown by Messrs. Jarman and Co., Chard. This exhibit forms a bright feature in a table group and attracts much attention.

TULIPS

Never before have Tulips been shown at the Spring Show in such luxuriance and beauty, and one fears that it may be many years before such a glorious feast of colour is again placed before the public. The season which has been responsible for the absence of various other flowers which are usually to be seen at Chelsea has suited the Tulips admirably.

The Old English Tulips, which it seemed only a few years ago were definitely relegated to the past and were likely to be almost forgotten, now appear to be fast coming into favour again, and small wonder when one realises their charm of marking and colouring.

In Messrs. Barr's most gorgeous and quite immense collection of Tulips of all possible sorts, the several vases of such bizarres as James Wild, Sir Joseph Paxton and George Hayward are quite delightful, but there are also many bybloemens and roses of equal beauty. In this memorable collection, which, by the way, was immensely improved from the spectacular point of view and also in educational value by the charming finish of the bordering of Irises, Trollius, Iberis, Saxifrages and many other border flowers, the vases of such May-flowering sorts among the very many, as Inglescombe Pink and Margaret and the rich yellows of Bouton d'Or and Mrs. Moon adjoining the intense scarlet of Europe, are wonderfully fascinating. The black Tulip always intrigues one, though none is really black, and among Messrs. Barr's collection are to be seen splendid examples of La Tulipe Noir, the darkest, blackest maroon of all, Faust and Kepla.

Dark coloured, nearly black Tulips are also very prominent in the large collection by Messrs. R. H. Bath, Limited, who have of this shade, Von Jehring, Gryphus and Zanzibar. Of their rose flakes and feathers, Brightness, The Minister and Milton are very fascinating. For elegance few equal Gesneriana major and Cherry Ripe.

Parrot Tulips do not flower freely in everyone's garden, but Messrs. Dobbie and Co. seem to have no difficulty and they are showing a great variety of this quaintly fascinating type which have great decorative possibilities. Café Brun, Fantasy, Markgraaf, Sensation, Perfecta and Chamoise Brilliant are the names of some of the most showy of these Parrot Tulips. In the same collection the rich yellows of Mrs. Moon and Inglescombe Yellow are most satisfying.

Those who seek suggestions for colour schemes should make a point of visiting the stand of the Anglesey Bulb Growers' Association, where in the centre they will find a most happy association of Bouton d'Or (of immense size and great quality), Prince Albert, Lord Cochran and Boadicea. The combination of deep yellow, bronze and bronzy-scarlet is perfectly delightful. Along the front of this collection there are several vases of "Baby Darwins" which are really blooms from small offset bulbs. The result is charming little blooms

which would be perfectly delightful for dinner table decoration and anywhere where small blooms are required. Baby Millet, Baby Greuze and Baby Suson are the sorts shown. But a word of warning is perhaps needed—it is not in every garden that these "miniature" Tulips can be flowered, delightful as they are when it is accomplished.

Tulips of garden value are also shown by Messrs. Rich and Co., and Mr. Alfred Dawkins. The latter has gorgeous vases of Mr. Farncombe Sanders, Ellen Willmott and the like, and they are associated with excellent Dutch Irises.

BEGONIAS

Messrs. Blackmore and Langdon, Bath, are to the front again with their wonderful tuberous-rooted Begonias. Superb examples of cultural

BEGONIA QUEEN OF THE BELGIANS.

skill characterise each individual plant. Form and colour are exemplified in the numerous novelties and standard sorts. The plants are charmingly disposed among Ferns as a groundwork, and with basket Begonias set up on standards all combine to make a glorious display. A few of the more noteworthy sorts are to be seen in Peace (a lovely cream), Mrs. J. S. Brunton (wonderful form and charming salmon-pink colour), J. W. Pymon (brilliant scarlet), Queen of the Belgians (deep salmon-pink, lovely wavy form, extra large flower), Sir J. Wilson (bright scarlet, shaded orange). The best yellow is Mrs. J. Davidson, beautiful Camellia form and, undoubtedly the best white is Nurse Cavell, a chaste sort of great purity. A deep glowing crimson sort is Grand Monarch, and a striking rose-coloured variety is to be seen in the lovely Lucy V. Toner, unsurpassed for form and beauty. In honour of the golfer, James Braid, this firm has named a beautiful crimson scarlet sort of good form and they well maintain their reputation with this handsome Begonia. The better basket sorts are Stella, a very clear deep rose sort; Edith, a blush-tinted white sort; and the light and graceful Carminea, all most useful for this work.

SWEET PEAS

About one half of the space allotted to Messrs. Dobbie and Co., Edinburgh, is occupied with a highly attractive display of Sweet Peas set up in pleasing fashion in tall stands, vases, bowls, and associated with bright green fronds of Asparagus Sprengeri. The background of black velvet adds very materially to the general effect. Conspicuous sorts are Royal Scot, a leading scarlet; Renown, charming rosy-cerise; George Shawyer, a salmon sort of splendid quality; a novelty named Fairy Queen, cream pink and very delicate colour; Kenneth, a dainty rosy-cerise and Orchid, a lavender of wavy form, of high quality. Gladys is also a lavender sort but of paler colour. The list may well include Dobbie's Orange, a standard deep orange self. The finest white in cultivation is generally regarded as Constance Hinton, and this chaste sort is to be seen in fine form and condition. There are no fewer than about thirty-sided leading varieties all worthy of careful inspection. This fine exhibit is staged in No. 1 tent on the west side.

Exceedingly fine is the exhibit set up by Messrs. Alex. Dickson and Sons, Limited, "Hawlmart," Belfast, comprising no fewer than forty of the leading novelties and standard sorts. There are at least ten thousand sprays of blossom beautifully disposed in this wonderful display, and the Sweet Pea has never before been more attractively exhibited. The staging is draped with black velvet, and the background hung with festoons and chains of Smilax. A few of the more conspicuous varieties to call for special mention are Faerie Queen, apple blossom colour on cream ground; Powerscourt, a magnificent flower of a beautiful lavender colour—two leading novelties that should be seen by all lovers of the Sweet Pea. Others are Royal Scot, orange scarlet, as exhibited; Hawlmart Cream, a beautiful cream; Tangerine, a striking orange sort; Hawlmart Pink, a lovely salmon-pink; Mrs. Tom Jones, regarded as the best of the blues; and Constance Hinton, undoubtedly the best white.

It is a great pity more space is not allotted to the Sweet Peas set up by those excellent growers, Messrs. Andrew Ireland and Hitchcock. Mr. Ireland has long been in the forefront of all that concerns the progress of the Sweet Pea, and in this case his bright, fresh and attractive Sweet Peas have all been grown in a cool greenhouse. Tangerine Improved is certainly a fine orange sort, so, too, is Mascott's Helio, a pale heliotrope sort of great beauty; Bunt, orange salmon of striking character; Royal Purple, a noteworthy purple; Hawlmart Pink, salmon pink; Shamrock, rosy mauve, a variety which gained an award of merit at Wisley last year; and Mascott's Scarlet, a new and noteworthy scarlet sort.

The table group arranged by Mr. J. Stevenson, Wimborne, is another instance in which larger space is denied, yet the display is highly attractive, being charmingly arranged. The arrangement of the flowers leaves nothing to be desired, the stands being finished off with Asparagus plumosus and A. Sprengeri. We must mention a few sorts of special merit such as Poppy, orange scarlet; Wild Rose, aptly named for its colour; Cynthia, very pale heliotrope—almost blue; Fair Lady, apple blossom colour on cream ground; and Diana, a splendid lavender variety.

Mr. Robert Bolton is treated more generously in regard to space, and in his exhibit are included charmingly arranged vases of blooms of remarkable colour, good form, and splendidly fresh. Graceful fronds of Asparagus Sprengeri add to the general effect. Courade, apple blossom colour on cream ground; Wonderful, the only true scarlet; Elsie Dene, a charming lavender,

and a charming orange self to be named, we believe, Wizard, represent four novelties of sterling merit. Standard sorts such as Picture, apricot; Gloriosa, orange scarlet; R. F. Felton, lavender; and Felton's Cream, are all to be seen in fine form.

ANNUALS

To what a large extent the annual plant modifies the design of the present day garden is reflected in the magnificent displays put up every year at this wonderful Chelsea Show. For the limited-time gardener, the lazy gardener, and the impatient gardener, the hardy and half-hardy annual can never come amiss. For the first named a sprinkle of seed on the ground, a rake over, perhaps an occasional watering, and perchance a thinning out, that is the time expenditure for a crop of flowers. The lazy gardener delights in the annual because it saves him from the more complex phases of herbaceous and perennial cultivation, while to him of scanty patience it is a veritable inspiration, cutting out entirely the long wait of many months, or probably a year or two, for the floral beauty which is the goal of all gardeners' desires.

But to get the best even out of annuals demands a qualification of this philosophy. Spring sowing and a few weeks growth will not produce specimens of Clarkias, of Schizanthus, of Nemesis, or of Mignonette, such as we see staged here by such experts as Messrs. Sutton, Messrs. Webb, Messrs. Carter, and Mr. Alfred Dawkins. These proud pyramids of bloom represent single plants raised from seed last autumn and cultivated with care and forethought throughout the winter months, particular attention being given to potting on just as the root system demands. It is this building up and encouraging of strong growth underneath the soil before the foliage makes such headway that ensures a specimen plant capable of responding to good culture with a lavish wealth of flower.

Messrs. Sutton and Sons of Reading have surpassed themselves this year and that is surely high praise. For 170ft. in the west tent their display extends in bay and promontory, a continuous pageant of changing colour. Here a tall background of Lavatera "Loveliness" (pure deep pink), forms a fine setting for white and pale pink Cineraria stellata, bordered by white Primula obconica and pink Nemesis; there, towering plants of Salpiglossis, a superb strain this is, give elevation to a charming bed of large-flowered Schizanthus, fronted by the annual Phlox Fireball, whose vivid crimson contrasts nicely with its own foliage of vivid green. Further on a huge bank of Cineraria stellata, blue and white shades, is used as a foil to a foreground of Dimorphotheca aurantiaca, mingled with semi-tall and dwarf blue Lobelia. This gives an excellent hint for summer bedding. In other parts of this great stand Schizanthus in endless variety of colour are effectively grouped, while Clarkia "Salmon-Scarlet" is conspicuous as towering pillars of warm tones against the cooler shades of Schizanthus and Nemesis Suttoni. The variety of the last mentioned, called Aurora, should be noted as an edging plant for taller things.

Messrs. Carter of Raynes Park, will attract the attention of the multitude with a large and beautifully planned exhibit occupying some 2,000 square feet in a central position of the great eastern tent. The pivot of this ambitious scene is a tall pyramid of well grown Clarkias surrounded by equally well cultivated Schizanthus in pots, mixed with the new Dutch strain of Spanish Irises, the lavender tones only being employed. Surrounding this are bold masses of large-flowered Cineraria Brilliant

Prize. In the same scheme and forming a circular island bed is a group of annual Delphiniums in which some pretty lavender shades mingle with the typical blues. The whole exhibit is buttressed at the four corners with solid mounds of Cineraria stellata and cactus-flowered alternately. Between these it is worth noting the bedding effect of white and crimson Brompton Stocks and a fine pink variety called Empress Elizabeth.

Messrs. Webb and Sons of Stourbridge make the most of a rather restricted space by putting up fine breadths of Cineraria in various shades and well bloomed plants of Schizanthus. One might almost call this a Schizanthus year, for they form the *pièce de résistance* of quite a number of the stands devoted wholly or partially to annual flowers. Those shown by Baron Schröder reflect much credit on Mr. Henderson, under whose able guidance they are grown, a particularly notable variety being a pure white of excellent bedding habit, requiring no pinching or training, as it grows dwarf and branching quite naturally. This

MESSRS. LAXTON'S STRAWBERRY, SIR DOUGLAS HAIG.

one is called Bridal Veil, and comes true from seed, a valuable acquisition.

Another excellent collection of these plants is staged by Messrs. Godfrey and Son of Exmouth, who have used quite small pots, none of them exceeding 5ins. in diameter, yet the flowers are as large and as beautifully coloured as any in the Show.

FRUITS AND VEGETABLES.

It has been said by a few "highbrows" that there is only a sheet of brown paper between Calcutta and a certain other place—there appears to be no limit to Cook's Tours these days. However, Chelsea might also be placed in the same category. Imagine a poor reporter working all day under canvas in a temperature about 100° Fahr.!

In one of these tents Messrs. Bunyard and Co. have a wonderful collection of Apples. The colouring and the general condition of the fruits emphasise the long keeping qualities of the different varieties, given proper conditions. After the terrific drought of last year it is really marvellous that these fruits have kept so well. There is no secret regarding their storage. Messrs. Bunyard

after a great many years of experience find that the best plan is simply to wrap each fruit in paper and place it in a box. Cold storage is unnecessary—a cellar or shed answering the purpose quite well.

As regards varieties, Allen's Everlasting is said to be one of the best for this time of year. The fruits are very firm and wonderfully coloured. Other well known sorts include Lord Derby, Bramley's Seedling, Bess Pool, Encore, Winter Queening, Adam's Pearmain, Wagner (very fine), Annie Elizabeth and Orleans Reinette. There are, besides those mentioned above, many beautiful fruits which are not quite so well known.

Messrs. Bunyard are not quite so well congratulated on their exhibit, which appeals to all who see it.

Messrs. Rivers have a fine exhibit of Peaches and Nectarines. Although the fruits are not so highly coloured as they usually are at Chelsea, they are excellent, taking into consideration the very late season. Among Peaches Duke of York is very conspicuous, and another good variety is Duchess of Cornwall. The best Nectarine un-

doubtedly is Cardinal, while their new variety, John Rivers, if looks are anything to go by, appears to be a good thing and should prove a great acquisition to this most desirable class of fruit.

The only exhibit of vegetables comes from the Hon. Vicary Gibbs (gardener, Edwin Beckett). The exhibit is typical of Aldenham and leaves nothing to be desired. Here are to be seen vegetables of the very highest quality, including Celery Aldenham Pink and Aldenham White, Pea Early Giant, Asparagus Perfect, Cucumbers Every Day and King George, Potatoes, Mushrooms, Tomatoes Golden Perfection (very finely coloured) and Perfection, Cauliflowers, Turnips and Mustard and Cross.

From Laxton Brothers come some delicious Strawberries which ever tempt the poor reporter to "pick and steal" the delightful, fragrant fruits. Their new Strawberry The Duke is the principal variety, and is likely to oust Royal Sovereign. The fruits are of good size, highly coloured and fragrant. Other notable varieties include Marshal Foch, a good maincrop variety; Lord Beatty, a large variety of excellent flavour; and that excellent forcing sort Sir Douglas Haig.

In next week's issue we shall publish detailed comments on Trees and Shrubs, Herbaceous and Rock Plants, Orchids, and Garden Sundries, with descriptions of noteworthy New and Rare Plants.

FIGHT THE BATTLES OF YOUR PLANTS

Plants and vegetables are constantly menaced by vicious enemies. The gardener must wage war upon them, the plants themselves are helpless.

HAS every garden owner got this idea fixed in his mind? He loves his plants, and grows his crops for the joy of growing them; can he therefore tolerate the thought for one moment that the well-being, maybe the very life of his plants, may be jeopardised if he neglects or even delays the use of weapons of destruction of insect pests? The season of quickened activity in the vegetable world is also the season of rapid multiplication of insects, both creeping and winged, and the tender young shoots and fresh young leaves of spring growth suffer accordingly. The power of an insecticide is very largely governed by the time at which it is used. Will my readers kindly read that sentence through again? It is the gist of the strategy that must govern our warfare against plant enemies, and in the great majority of cases the best time to use insecticides is when they are expected to appear on the scene rather than after their actual arrival.

For instance, the leaf-rolling aphid if it has troubled us in the past may be expected very shortly after young foliage is formed. If we wait until curled-up leaves indicate the presence of the pest, we have little chance of expelling him from his snug little home, because not only are the leaves rolled in such a manner as to render it extremely difficult for sprays to enter the interior channel, but that channel is screened by a fine film of water-resisting web or adhesive substance that isolates the aphides in a well secured strong room. Here, then, is one instance where the time of application of even the most efficient sprays makes a world of difference in results, and if I dealt at length now with spraying for leaf-rolling aphid I should expect those who started spraying forthwith to say, "There's not much in spraying."

It is quite a different story when we come to such pests as the caterpillars of the vapourer moth, the blister moth, the Currant sawfly, and a good many varieties of weevils that attack either fruits or vegetables.

Just at this season of the year it is possible to oust these chewing and gnawing vagabonds either by actually slaying them with what is known as a "direct contact" insecticide or by rendering the foliage of their host plant poisonous or so distasteful that the insects are glad to quit.

Direct contact insecticides are very effective provided in the first place they are accurately prepared and held in perfect suspension—they are not, generally speaking, truly soluble—and in the second place that the insects are get-at-able. Most of the random selection I named above are easily hit by a spray ejected by a good syringe or spraying machine, and we may consequently go at them with a good summer spray fluid. Here I am, as it were, between the devil and the deep sea. I want my readers to obtain information, and I know the question arising in their mind will be, "What do I recommend as a good summer spray fluid?" If I quote Messrs. So and So's speciality, I get some rude question asked me as to what my recommendation costs a firm, and some competing manufacturers write wrathfully to the Editor protesting that their speciality is equally efficacious. I might give recipes and advocate making insecticides at home were it not for the fact that I do not approve and never have approved of gardeners pottering about

with chemicals that want skilful handling and special equipment. An ill-balanced or carelessly mixed insecticide may easily be capable of working mischief instead of benefit, and then what happens? The blame is not connected with the blunder of the amateur dispenser, but is attributed to the bad teaching of the writer.

Yes; all things considered, I feel I am on the right track when I adhere to the view that the general gardener or amateur will be best advised to buy his insecticides ready made, and he will find good direct contact sprays in Katakilla, Kilzall, Abol and other brands of similar character. It must be borne in mind that anything that has acid, caustic or penetrating properties must be used with extreme caution if plants or trees are in active growth and young leaf. Poisons that will destroy insects may be quite safe as far as most foliage is concerned, and my faith in nicotine remains unshaken. I find that both under glass and in the open I can rid plants of caterpillars, weevils, aphides, and check the ravages of woodlice, earwigs and slugs by mixing up a soft soap solution and dropping a few spots of nicotine as used for vaporising into each gallon. Arsenate of lead wash is much used for fruit tree spraying, for a whole host of caterpillars, hoppers and small chafers. It is a spray that wants using with some care, and I would only recommend its use where a good powerful sprayer with a well made fine nozzle is available.

Ever so much trouble would be spared and ever so many plants would be kept in better condition if more attention was given to spraying before any trouble appears, using just a cheap, harmless mixture of quassia and soft soap. This has no dangerous elements and can be used on all except salad vegetables, its purpose being to make the foliage distasteful to insects. Moths and butterflies will not lay their eggs where there is a taint of quassia. Emulsified petroleum is also very serviceable for the same purpose, but to use ordinary lamp paraffin may cause trouble if not kept in perpetual suspension. Herbaceous plants, Roses, Calceolarias, Enonymus, Beans, Celery, Chrysanthemums, Dahlias and even Potatoes may well be sprayed with these mild insecticides, for be it noted if Potatoes are allowed to suffer from attacks of aphid they are very prone to collapse when later on they are sprayed with Bordeaux mixture to ward off blight (Phytophthora infestans).

At this season of the year plants under glass must be very carefully watched. As the sun gains power the temperature inside a small greenhouse rises rapidly during the forenoon, and if a plant should happen to droop for lack of water it is almost bound to fall victim to some insect pest, for the tropical atmosphere encourages them to breed at a terrific rate. White fly is an awful scourge. It matters not whether one grows Tomatoes, Fuchsias, Salvias, Primulas or any one of a score other subjects, white fly, if once it appears, multiplies until it comes in cloudlike masses, and the foliage of everything becomes horribly misshapen. Cyaniding is certainly an effective method of dealing with the pest, but cyanide wants very careful handling.

I have tried many things, but nothing has served me quite so well as Gassonite sprinkled over a damped floor at the time the ventilators are closed down in the evening. It is cheap, easy, safe, and if repeated at intervals of a fortnight

or so it will dispose of each successive host of flies as they are hatched.

Red spider would not give half the trouble it does among Vines, Cucumbers, Carnations and other greenhouse plants if attention was more carefully given to the maintenance of atmospheric moisture. Again, there is the case of Violets that have been producing a harvest of bloom in frames; now that the flowers are over the plants should not be left just to take their chance, but, if the weather is at all hot, should be syringed daily. Red spider cannot make much headway when constantly brought into contact with water.

A. J. MACSELF.

THE THINNING OF SEEDLINGS

Thin gradually and before the plantlets become drawn.

A GENERATION ago there was an old saying, "sow thickly and thin early." Such advice might be good when seeds were not as reliable as they are to-day. In these days very thick sowing would be a mistake. Taking plants from seed generally the seedlings require very severe thinning even after moderately thin sowing. With the exception of some of the rarer species and varieties, the great majority are sown too thickly, especially in boxes, pots and frames where space is strictly limited. I dare say hundreds of readers of THE GARDEN have already taken the required number of seedlings from the boxes of many kinds of plants and still have more left in the boxes than they took out. Of course, it is very nice to have a surplus of seedlings, but undue crowding makes all weakly to begin with and then valuable time is lost in strengthening those retained.

Hardy annuals from seeds sown in the open border should be carefully examined from time to time and the necessary thinning-out done gradually, so that after the final thinning the plants retained will have ample room in which to grow sturdily, keep an upright form and bear flowers of great substance. Weakly plants are never satisfactory.

Turning now to vegetables, Onions and Carrots more especially are often allowed to remain in very crowded state until the plants are quite large before any thinning is attempted, which is a great mistake. Others are gradually thinned so that the drawn seedlings may be used in the kitchen. This is a sound practice, provided the final thinning is not left until too late a date as, when this happens and a dry spell of weather follows, the matured crop is not quite satisfactory, even if wireworms and other pests do not attack the young plants. All seedlings not required should be drawn out while the soil is in a moist condition and immediately afterwards the rows of plants should, in the absence of rain, be watered through a rosed watering-can. A good hoeing of the soil between the rows should then be given as soon as it becomes dry enough, and a light application of soot, broadcast, will be beneficial.

If Onions are required for household purposes solely, thin to 2 ins. apart, Carrots to 4 ins., Turnips to 6 ins., Runner Beans to 8 ins., Parsley to 6 ins., Beet to 6 ins. It is very rare, indeed, that one sees Parsley thinned-out at all, but it pays to thin this crop well. Three plants in 10 ins. or so will yield finer and more bulky leaves than sixteen in the same space. Many gardeners think a little "drawing" does no harm. Never was there a greater mistake!

G. G.

CORRESPONDENCE

THE SCENT OF "HEAVENLY BLUE."

THERE are doubtless several "Heavenly Blues" in the nomenclature of garden plants. There is, for example, Heavenly Blue *Lithospermum*, but, such has been the popularity of the introduction, the best known is almost certainly the Heavenly Blue Grape Hyacinth. It is grown in countless thousands. Generally speaking, it is found in longer or shorter lines as edgings for beds or borders, or in the last named in clumps of greater or lesser extent. Occasionally we come across a large mass occupying a single bed. It is then that its wonderful scent can best be sampled. Those who stood beside such an one in that sudden warm interlude of May 8 and 9 will know what it is like. Some people say it reminds them of cloves. Some that it recalls the incense-like scent of *Matthiola bicornis*, the Night-scented Stock. Others simply describe it under the vague generalisation of spicy. There may be others still who are unaware that it has any smell at all. Let all such gather a handful and put them in a vase and leave them in a warm room. They will realise what it is then, and if they are of the same opinion as the writer, the first gathering will not be the last. Incidentally, it may be mentioned that their scent is an easy way of distinguishing Heavenly Blue from *Muscari botryoides*, the ordinary Grape Hyacinth, which when it has become established in a position that it likes is not always readily distinguished from it.—MÆLOR.

THE YELLOW CROWN IMPERIAL.

THE opprobrious epithet of Stink Lily, by which the Crown Imperial is known, does not lessen its claim to being classed among the best of early-flowering hardy plants. In support of this claim I may mention that there is, within view of where this note is made, a bold, irregular-shaped clump of the yellow variety, *Fritillaria imperialis lutea*, carrying about seven and a half dozen flower-spikes, the telling effect of which will be realised by those knowing this Lily; while, in addition to the drooping bell-shaped flowers, the smooth shining foliage is also attractive when closer inspection of the group is made. This plant will grow and flower in sun or shade, a sunny site giving one or two weeks earlier flowering. A border of shrubs will afford positions giving partial or total shade, as the case may be. The question has often been raised as to whether frequent replanting of the bulbs does or does not conduce to freer flowering. I incline to the "let alone" practice, in support of which may be cited the plants growing here, of which the clump referred to above has not been disturbed for, probably, ten years. On the other hand, a smaller colony was dug up about two years or so ago and replanted separately. Most of these are now flowering, which shows the Crown Imperial to be a plant quick to re-establish itself where conditions are favourable. The soil in which these Lilies grow is on the light side; indeed, it is inclined to be sandy, but at a spade's depth or so it is of somewhat heavier texture.—C. T., *Amphull*.

THE YELLOW BANKSIAN ROSE.

LAST year one of your correspondents drew attention in your columns to the early flowering of the Yellow Banksian Rose. Your readers may like to know that here (West Horsham) on the south wall of my house the Yellow Banksian came into bloom on Friday, May 12 remarkably early in what is a backward season for nearly everything in the garden.—J. C. F. M.

SPANISH GORSE.

THE so-called Spanish Gorse, *Genista hispanica*, is, in my opinion, a strangely neglected dwarf shrub. If planted in clean, not over-rich soil and in a position where it gets all possible sunlight and heat it proves hardier than many shrubs much more often seen in gardens, and if in an exceptionally hard winter—we have had none of late years—it gets cut, it is very seldom that it fails to shoot again from the base. For certain effects in garden planting its low mounding habit of growth is invaluable. It may be used at the margins of shrubberies, in the rock garden—where isolated specimens are often most effective—or in the wild garden. Wherever used it provides furniture throughout the year, and yet it is not, strictly speaking, evergreen, but the quantities of deep green stems and prickles are as effective as leaves. The blossoms, which at the time of writing (May 16) are almost at their best, are of a

short-lived and lose their stamina very quickly, and must be kept going by being continually raised from seed. Not many, I fancy, ever think of doing this. Hence *Fosteriana* and *ingens* are here to-day and gone to-morrow; *dasystemon* is quite different. It does not resent captivity and is a splendid doer. It has not the gorgeous magnificence of those Tulips which I have just named, nor their height. Not that they can be considered tall compared with the towering Darwins. Half a dozen inches is the measure of its stature, and its pretty white and yellow flowers, which are usually borne from two to four on a stem, are the personification of quiet beauty in their rather uncommon colouring of yellow and white. The great pure yellow centres with the ends of the petals pure white always have reminded me of that bright little annual *Limnanthes Douglasii*, whose colour arrangement I read the other day was described by no less an authority than Mr. Fraser, our new V.M.H., as altogether out of the ordinary. I suppose it is, but I never realised before that it was for the simple reason

THE SPANISH GORSE, *GENISTA HISPANICA*.

deep golden colour and are borne in clusters of a dozen or so in a manner reminiscent of the true Gorse. It may be well to make clear the distinction between this plant—the Spanish Gorse—and the Spanish Broom, or Rush Broom, as it is also called (*Spartium junceum*), another valuable golden-flowered shrub, but summer flowering and as different in habit of growth as one shrub can be from another.—G. HARVEY.

A BEAUTIFUL TULIP SPECIES.

THE charming little *Tulipa dasystemon* is one of the comparatively recent introductions from Turkestan. From a quotation in Bailey's *Encyclopædia* it rather astonished one of the first people who cultivated it by flowering a second time as well as it did the first year after its importation from mid-Asia. What would have been that person's surprise to find it flowering equally well year after year, and not only flowering, but setting seed and sowing itself "all over the place." It is not every Tulip species that does this. So many are very disappointing when they are caged up in a Western garden. Perhaps they are by nature

that, in times gone by, my garden was overrun with it, and familiarity breeds contempt. There is a third flower which may be put in this small and select class. It is a *Sparaxis* called *Angelique*. In the warm sunlight it might for all the world be *dasystemon* on stilts. *Tulipa dasystemon* is not only a gardener's flower, it is also of special interest to the botanist, as the arrangement of its central organ is unlike what we find in most Tulips, inasmuch as there is a distinct style to the pistil and so the stigma does not sit directly on the ovary. Hence it finds itself relegated to a small sub-division of the genus *Tulipa* called *Orithyia* whose members, until the advent of *dasystemon*, were all looked upon as garden Cinderellas of the Tulip family. I rather think a very rare British plant, *Lloydia serotina*, must be nearly related to it.—JOSEPH JACOB.

THE MOSS ROSE.

I AM not surprised that Major Hurst's scrappy and very questionable notes on the Moss Rose, which appear in "The Rose Annual" for 1922 should have attracted the attention of "J. J."

The question raised by the latter can easily be answered. Was there, as Major Hurst states, a Moss Rose in 1606? Upon the evidence submitted for the reader's consideration the answer is absolutely and without the slightest qualification a negative one. Major Hurst bases his supposition, for it is nothing more, on the following ground, and I will quote his own words: "But this is not the earliest date recorded for the Moss Rose, for in a rare little book entitled "L'école du Jardinier fleuriste" Fréard du Castel of Bayeux (1746) states that the hundred-leaved Moss Rose was in cultivation in the North West of France at Cotentin, Bessin, and a part of the littoral of La Manché in 1746; and that it was brought there by him from Carcassonne in the South of France, where it had been known for half a century (1606)." Major Hurst has evidently made this statement on some other authority than "L'école du Jardinier Fleuriste," and there is no wonder that "J.J." cannot find any reference to the Moss Rose in his copy. I cannot understand how it is that "J. J." says "the edition in my possession is dated 1746, which is the identical one from which Major Hurst quotes." The first edition of "L'école du Jardinier Fleuriste" bears on its title page the date in Roman numerals thus: M.DCC.LXIV. I cannot make 1746 of that, but 1764. The book was published anonymously, Fréard du Castel being only the reputed author. The writer nowhere mentions the Moss Rose in that book, nor does he mention any of the places referred to by Major Hurst, either in the North-West or in the South of France. The reference to the flower having been grown for half a century in or near Carcassonne is not contained in this work as quoted by Major Hurst. There is only one purely French floricultural book known to me as having been published in 1746, and that is the Père d'Ardène's treatise on the Ranunculus. Major Hurst's notes must have got mixed for such a substantial blunder to have taken place. The facts may be true, but so far as the authority quoted is concerned, the whole story is apocryphal.—C. HARMAN PAYNE.

COLOUR AND PLANT LIFE.

INOTE that Mr. George Garner in his article on "The Shading of Greenhouses," in THE GARDEN of May 13th, writes that for Ferns and Palms a permanent green shade is best for the summer months. I take it that by permanent he means a shade which cannot be rolled up and down like a blind but remains fixed all through the warmer months, whether the day be clear or cloudy. Mr. Garner expressly limits the use of such a shade to Ferns and Palms, and they would certainly be less liable to injury by the use of it than other classes of plants. In these days when labour-saving is a great consideration anything which economises time gains importance, but it must be remembered that the permanent green glass shading was removed from the great Palm House at Kew and also from the Fern houses. These last named were glazed with a much deeper tinted glass which was found to be positively injurious and removed (see the *Gardener's Chronicle*, November 26, 1892). A short digest appeared in THE GARDEN early in 1919 from the Rev. G. Henslow's paper on "Some Effects of Growing Plants Under Glass of Various Colours," which was read at a meeting of the Scientific Committee of the R.H.S. and published by them, and the editorial comment was that "the important point for practical gardeners to observe is to avoid the use of green colouring matter when summer-clouding their plant houses." Experiments showed that not only did the green screen cut off a certain amount of heat, but the more important rays, which are required for assimilative purposes. Plants grown

under green glass were actually found to lose weight of dry substance though there was an increase of water. A plant appears to be green because it *absorbs* the other rays which make a white Solar light, but rejects these green rays. To an animal oxygen is life and green restful; to the plant oxygen is largely rejected and the colour green poisonous. It is a very remarkable thing that in some lights chlorophyll appears to be blood red, and it fluoresces with a red light. We speak of our green lawns, but if we look at them through purple glass, which cuts off the green rays from the eye, they appear red. This chlorophyll or leaf-green is by no means a simple green colour screen, and "no advantage seems to have resulted" from the use of a green pigment to quote Dr. Lindley (see page 300 in his "Theory of Horticulture").—H. H. W.

IRIS—FLEUR DE LUCE.

Flower of light! who gave thee first that name
Saw clear thy flower soul through purple prism bars.
Lifting thy threefold standard to the stars,
Poised, perfect, still,—like an arrested flame,
A carven prayer all luminous, thou art
Part human flower and winged Archangel part.

Flower of light! Fair prism that disparts
But to remake the Sun's too sovereign light,
Tempering his blinding, incandescent white
In Iris colours to our human sight,
Filling with uncommunicable joys our hearts:—
As the arched splendours of God's rainbow, blent,
Make the white glory of His Firmament.

Flower of light! Emblem of Hope, that calls
With lifted arms to Heaven, but still lets down
The curv'd beauties of thy triple gown
To Earth: as we too, reaching to a crown
Hold fast to human love, so thy soft velvet falls,
Emblem of Faith and Hope and Charity
That, rooted still in Earth, still clasp Eternity.

Flower of light! All colour and all form,
The very Curve of Beauty, in thee dwells,
Not even the multitudinous Sea and all its shells,
Whether in halcyon calm it laughs, or swells
Magnificent in mountain-billowed storm,
Shows curves like thine, so carven yet so free;
Nor Phidias knew, nor could Apelles see
More perfect form or colour than in thee.

Flower of light! Who knows if fables old
First gave Olympus' messenger thy name
Or gave thee hers;—but this I know—there came
Down the arch'd bow in multicoloured flame,
To star our Earth with purple and with gold,
Thy beauty;—for a breath of Heaven yet clings
About thy robes, and thy translucent stillness brings
Faint Seraph songs, half heard, and winnowings of
wings.

W. H. W. BLISS.

ROSE LA FRANCE UNDER GLASS.

ITHINK it might interest your readers to hear of a wonderful La France Rose tree I have in one of my smaller greenhouses. This tree begins blooming in March and goes on for many weeks. This season my gardener has cut over three hundred blossoms off it, and this number is about the yearly average since the tree began blooming about eleven years ago. The gardener tells me he cut the first Rose this year on February 24, and he cut the last on May 12. We give the tree no artificial heat, but it is well pruned back every season after flowering ceases, and given bone meal in the autumn and liquid farm-yard manure occasionally. I can highly recommend this good old variety of Rose to anyone who wants lovely fragrant blooms in early spring.—FLORENCE E. HENDERSON.

GARDENING OF THE WEEK

FOR SOUTHERN GARDENS.

The Kitchen Garden.

Brussels Sprouts.—The plants from an early sowing under glass pricked out and grown on as advised in a previous issue will now be strong enough to place in their permanent positions. A fairly rich well worked piece of ground should be allotted this vegetable to get a heavy yield of buttons. Plant firmly in rows a yard apart for the tall-growing varieties and 6 ins. less for dwarf ones, and allow corresponding distances from plant to plant in the rows. Choose, if possible, a dull or showery day to get the work done.

Chicory.—Where this vegetable is required seed may be sown now in an open situation having a good depth of soil but not necessarily recently manured. Draw the drills from 15 ins. to 18 ins. apart, and thin the seedlings from 6 ins. to 9 ins. apart.

Haricot Beans are a most valuable winter food and well worth some good ground. The sowing and subsequent culture is similar to that afforded to dwarf French Beans with the exception that the Haricots are not gathered in the green state but allowed to develop fully and ripen to maturity as a seed crop. Among several to choose from I know nothing better than the Dutch Brown.

Cucumbers.—Excellent crops of Cucumbers can be grown in frames for the next few months. Frames that are cleared of early Potatoes, etc., are suitable for this purpose. Naturally, better results will be obtained if a little fresh hot-bed material is introduced to give the plants a start, but quite good crops can be secured by merely digging over the frames, at the same time working a little artificial manure in and planting out at once.

The Flower Garden.

Spring-flowering Plants.—The majority of these are several weeks later passing out of flower this season, and will therefore delay the replenishing of the beds with the summer occupants. Where the bulbs of Hyacinths, Tulips, etc., have not completed their growth at the time of lifting they must be laid thinly out in trenches of ashes or soil until they have done so, and then lifted again and spread out thinly in a cool, dry, airy shed. Roots of Polyanthus may be divided and planted out on a cool border in rows a foot apart. Aubrietias and Arabis can be easily increased by cuttings, which will root readily in sandy soil in a cold frame. The former are also easily raised from seed sown now, and this is a very easy way of getting a quantity together where it is not essential each plant must be true to colour. Forget-me-nots when lifted can be planted somewhat thickly together on a spare piece of ground which has several inches of light sandy soil on the surface, and there will be an abundance of material for pricking out later on. If possible, it should be arranged for the beds to be dug over and left a few days after removing spring plants before they are again filled up with fresh stock.

The Hardy Fruit Garden.

Raspberries.—Remove all superfluous and weakly growths, retaining sufficient only for fruiting next season. The removal of unnecessary shoots must be done carefully or injury will be done to the feeding fibres of this season's fruiting canes. The spaces between the rows should receive a light surface hoeing to keep small weeds in check. Should no mulch have been given, it should be done now, especially on light land. If no manure is available, throw some lawn mowings and leaves together for a few days and let this be used as a mulch.

The Strawberry Bed should be properly weeded before bedding it down with some bright straw in readiness to keep the fruits clean. At the same time all netting arrangements should be carried out.

Fruit Under Glass.

Early Peaches and Nectarines.—Owing to scarcity of sunshine it is as a rule more difficult to obtain a good finish in appearance and flavour with the above than with the mid-season and late fruits. Much, however, may be done in reaching these ends by careful and practical management. An important aid in obtaining flavour, particularly so when there is a lack of sunshine, is to see that the hot-water pipes are never allowed to become cold day or night. By

this means a circulation of air may always be kept on the house, and a fairly warm, buoyant atmosphere is of the utmost importance in giving flavour. Warm moving air aids also greatly in giving a good colour to the fruits, especially when they are exposed nicely to the light and lateral growths not allowed to check it. The condition of the roots is also of immense importance, and although it is fatal for the roots to suffer from dryness until the fruits are fully matured, it is directly harmful to give a lot of water to any tree approaching ripeness. Arrange rather for all copious waterings to have been given before this stage is reached. H. TURNER

(Gardener to the Duke of Northumberland),
Albury Park Gardens, Guildford.

FOR NORTHERN GARDENS.

The Kitchen Garden.

Turnips.—Make further sowings of the Milan type so that nice fresh roots may be ensured. Thin early sowings as required and keep the Dutch hoe going between the lines, and in this way encourage a quick yet vigorous growth.

Kidney Beans.—The main crop of these may now be sown without danger of late frosts affecting the plants. Choose a light and friable piece of ground which has been well manured during the winter period and sow in lines 18 ins. apart. Thin freely to about 8 ins. when the rough leaves appear.

Runner Beans.—These are less hardy than the dwarf sorts, but may also be sown now. The rows should be at least 5 ft. apart, as when grown too closely the crop is considerably diminished. It always pays to give ready support by stakes or strings immediately the plants are a few inches high. In many gardens climbing Beans are grown on tripods made up of three very tall canes, and when arranged thus at regular intervals by the sides of paths the result is both effective and remunerative.

Peas.—Numerous sowings should be made now to provide late crops. The Gladstone and Autocrat are two excellent sorts for late work, both being of robust constitution and producing large pods with Peas of excellent flavour. Attend to the staking of earlier sowings as required, and mulch with half-rotted manure crops that may be growing on light or gravelly soils.

Potatoes.—Fork the soil between the rows and give a light dressing of Potato manure immediately before earthing up. Nothing responds more readily to generous cultivation than the Potato. When growth is vigorous the plants are less liable to disease, with resultant increase of crop.

Saladings.—Keep up a succession of Lettuce, Radish and Mustard and Cress. Also transplant previous sowings of Lettuce into suitable quarters. To produce the desired crispness in Lettuce the crop should be grown quickly and receive copious waterings during dry weather.

Spinach.—Make further sowings of this vegetable on a cool part of the garden, preferably on an east or north border. When sown in this position the crop does not run so readily to seed during hot weather. A sowing of New Zealand Spinach should also be made now, but a warm and dry position should be accorded this variety.

Seakale. Examine new plantations with a view to disbudding, leaving one strong crown to develop.

The Hardy Fruit Garden.

Wall Trees, such as Peaches, Nectarines and Plums, will greatly benefit by a good syringing each day during fine weather. See that newly planted trees do not suffer from lack of water at the roots. A goodly mulch of partly rotted manure will prove beneficial and prevent over-quick evaporation.

Raspberries.—Suckers are now pushing up freely around the parent plants, so should be reduced to the quantity required for next season's fruiting.

Fruit Under Glass.

Mealy Bug on Vines.—Unfortunately in many establishments where the vineries have to be utilised at certain periods for plants mealy bug readily finds its way into the structure, and when this pest has obtained access it is a difficult business to eradicate it, no matter how thoroughly the work of cleaning during the winter has been done. A sharp look-out should be kept for the bugs, and if touched with a small brush dipped in methylated spirits it will check their career sufficiently to save the bunches from becoming infested.

The Flower Garden.

Bedding Out.—Most of the summer bedding plants may now be transferred to their flowering

quarters, with the exception of Begonias, Heliotropes, Ageratum and Dahlias, which might more safely be left till the last.

Polyanthuses.—Plants raised from seed sown under glass should now be pricked out into nursery beds on a partly shaded border. Old plants may also be lifted and divided at this time, planting them in a fairly rich piece of ground. In this way fine plants may be obtained for autumn bedding.

Sweet Peas will now be growing freely, so should receive attention in the way of staking before the growths fall over. Where the plants are grown singly with a view to the production of large flower-spikes the growths should be disbudded and tied in regularly.

JAMES McGRAN,
(Gardener to Sir Henry H. Houldsworth, Bart.),
Coodham, Kilmarnock.

CONSERVATORY AND GREENHOUSE.

Agathæa cœlestis, the so-called Blue Marguerite, is a very pretty plant for conservatory decoration, producing as it does its small blue flowers in great profusion over a long period. It is easily propagated by means of cuttings at any time, and thus may be had in flower more or less all the year round. There is a variety with larger semi-double flowers, but it is not such an elegant plant as the type. There is also a variety with a lax trailing habit which is very pretty for baskets.

Oxalis floribunda, which has been in flower for some time, is very pretty for the greenhouse stage, both the type and the variety alba producing their flowers in wonderful profusion. They are also very fine when grown as basket plants.

Oxalis purpurata (syn. *O. Bowieana*), which flowers later than *O. floribunda*, is also very fine. As their foliage dies down water should gradually be withheld, and they should be given a rest and kept dry in a cold frame. During September they should be turned out of their pots and re-potted; they may be grown in a cold frame from which frost is excluded.

Chænostoma hispidum is a very pretty plant for the cold greenhouse stage. It is a neat little bushy plant, and produces its small white flowers in great profusion over a long period. It is easily rooted from cuttings at any time. This plant is a native of South Africa, and only requires cool greenhouse treatment during all stages of its growth.

Alonsoa Warscewiczii is a popular half-hardy annual which if grown in pots is very useful for conservatory decoration at this time. The less known *Alonsoa incisifolia* is also a useful and beautiful plant, and this particular species is propagated by means of cuttings. By propagating successive batches it may be had in flower all the year round.

Begonia manicata in its way is the finest of all the winter-flowering Begonias. In addition to its elegant sprays of flower it lasts in good condition for well over three months, that is, if it is kept in a cool house when in flower. Most cultivators keep it in a stove temperature, under which conditions the flowers come a poor colour, and only last for a few weeks. From now until the end of the month is a good time to propagate this Begonia by means of cuttings, which root readily in a close case. When potted off and growing they require a genial growing temperature of some 55° to 60° until the flowers show signs of colour, when they should be removed to a cool house. The first season their flowering pots should be 6 in. or 7 in. in size. After flowering they should towards the end of May be potted on until they are in 10 in. and 12 in. pots, in which they should make fine specimen plants 6 ft. to 7 ft. high when in flower. Such specimens are invaluable for grouping in a large conservatory.

Begonias of the winter-flowering section, of which *B. secotiana* and the tuberous-rooted varieties were the progenitors, should now be giving plenty of good cuttings, which should be secured when some 3 ins. to 4 ins. in length. These root readily in a close case with bottom heat at command and a top temperature of 55° to 60°. When rooted they should be potted on as they require it. During their growing season their cultivation is not difficult, as they grow freely in an intermediate temperature of some 55°. Careful watering is, of course, essential at all times. A few of the best varieties are Optima, Mr. Heal, Elator, Exquisite, Emita and Fascination. The double-flowered varieties do not succeed near London, as they drop their buds during foggy weather. J. CUTTS,
Royal Botanic Gardens, Kew.

ANSWERS TO CORRESPONDENTS

THE GREENHOUSE.

PLANTS FOR A COOL GREENHOUSE (N. E. Devon).—We fear our correspondent is inclined to expect over much from the greenhouse which it is intended to heat by artificial means during cold weather to about 40° Fahr. This being the case, the idea of growing such plants as Gardenias and Allamandas, for instance, must be abandoned. Of the other climbers mentioned the Heliotrope, Niphetos Rose, *Plumbago capensis* and *Solanum jasminoides* are quite suitable, though for the *Solanum* we should be inclined to substitute *Mandevilla suaveolens*, as the *Solanum* could be grown out of doors if it were given the protection of a wall, or it would flourish if planted in a moderately warm corner where it could ramble over some unvalued shrub. For the three pillars in the greenhouse we suggest Heliotrope, *Plumbago capensis* and *Cassia corymbosa*. As it is intended to grow as many plants in the house as possible, climbers should be trained to the roof sparingly or they will cast too much shade for the well-being of the other plants. A word of warning against attempting to grow too many plants seems to be needed. Overcrowding is very harmful to all living things and we are of the decided opinion that it is far better to allow a limited number of plants fair space than to "squeeze in all that I can and hope for the best." With regard to Camellias, we have found it best in the West to plant them in a north-west aspect where they flower later and often escape the frosts that would otherwise spoil the blooms. The cause of failure with Lilliums out of doors is probably unsuitable soil. If Azaleas and Rhododendrons are grown many Lillies might be planted among them with prospects of success.

TREES AND SHRUBS.

BROOMS (Felsted).—*Cytisus kewensis* is one of the finest of the prostrate Brooms as it makes trailing shoots a yard long, covered with large creamy-yellow flowers. A stronger plant, with bright yellow flowers, is *C. scoparius prostratus grandiflorus*, of quite a prostrate habit. Small plants more suitable for the rockery are *C. Beani*, and *C. decumbens*, with yellow flowers. *C. Ardoini* is a beautiful little Broom, with yellow flowers, and erect, but only 6 ins. high. *Gemista pilosa* and *G. prostrata* are both small, procumbent yellow Brooms suitable for the rockery. *G. Hispanica* or Spanish Gorse is not procumbent, but forms an erect, spiny bush 12 ins. to 18 ins. high, covered with yellow flowers. The large bed at Kew contains many plants. A fine effect can always be produced with the above mentioned small Brooms, by planting a sufficient number of specimens to cover the area available.

FRUIT UNDER GLASS.

FIG WHITE ISCHIA (Felsted).—This Fig produces small fruits, of pale colour when ripe, and in great abundance. It is, therefore, well adapted for pot culture. The small fruits now appearing on last year's shoots should not be picked off, because they may be the only ones that will ripen in a conservatory that is not heated in spring and early summer. This is what is termed the first crop. The second will appear on this year's growths, but may not ripen without artificial heat.

MISCELLANEOUS

ACETYLENE GAS REFUSE (H. M. L. Kensington).—The refuse from acetylene generators should be left exposed to the air for three to six weeks before it is spread on cultivated ground. After that it may be used for any purpose for which lime is used in the garden and may be put on the ground at the rate of 1 lb. to 1½ lb. to the square yard.

THE DESTRUCTION OF SPARROWS (P. D., Glasgow).—The use of poison in the garden for any such purpose is greatly to be deprecated: also it is not possible to place any which, if eaten would not be equally harmful to poultry. To reduce the number of sparrows, which have become so destructive, better plans than poisoning are either to shoot them or catch them after dark in nets. With the former plan a little soft food may be placed on the ground near where the sparrows congregate, and when a number are feeding they could easily be shot if the gun-man is hidden within range. We need scarcely emphasise the necessity for extra caution in the use of firearms directed to objects on the ground. Successful netting is only carried out when the sparrows roost in such cover as that provided by Ivy on walls, from which the birds can fly out only in one direction. If four men or lads are available—two to hold the net, which is attached to a couple of long poles, and one on each side to beat the Ivy—the success of the foray will be all the greater. All the sparrows' nests should be pulled out frequently during the spring and summer in order to prevent increase.

NAMES OF PLANTS.—L. M. B. E., Melrose.—Seedling^s of *Primula hirsuta*.—W. S. M., Tunbridge Wells.—*Acetylano des*, "Norway Maple."—H. P. E., Teignmouth.—*Bilbergia nutans*.

SOME BEAUTIFUL BARBERRIES

FEW shrubs contribute more to the brilliance of the garden at this season than the Barberries. The particular kinds which are represented by the drifts of orange and gold are old favourites, being *Berberis Darwinii*, introduced from Chile in the first half of the nineteenth century, and *B. × stenophylla*, an accidental hybrid between Darwin's Barberry and *B. empetrifolia* a pretty but not conspicuous species. *B. stenophylla* is to-day one of the commonest shrubs; it is also one of the most worthy.

Many seedlings from *B. stenophylla* have been dignified with names. They mostly show a tendency to revert to the more richly coloured but stiffer *B. Darwinii*. Some are none the less not without value for special purposes. Such are the very compact habited *B. s. Irwinii*, useful in the rock garden; the richly coloured *B. s. corallina*, the buds of which are orange vermilion; and *B. s. Brilliant*, which is semi-deciduous and has brilliantly coloured foliage in late autumn.

The only other species—apart from the Mahonias, of which more anon—which could by any stretch of the imagination be called showy is *B. dulcis*, better known in gardens as *buxifolia*. Its lantern-like golden yellow fragrant blossoms are so spaced as to display their individual beauty, but the shrub does not afford the blaze of colour produced by *B. Darwinii* and its relatives. The very compact form of *B. dulcis* (*B. d. nana*) is suitable for the rock garden. It is showier when in flower than the typical plant.

There are several evergreen Barberries with much larger leaves than those we have been

considering, some of them reaching 3 ins. or more in length. The foliage of these is invariably glossy and rather striking, but the flowers, produced more sparingly than with the *Darwinii* forms, are primrose or pale sulphur yellow in colour. The nomenclature of these species is in nurseries very confused, but the plant usually offered as *B. Wallichiana* or sometimes as *B. Jamesoni* is *B. Hookeri* (Lemaire). This rather spreading evergreen shrub attains a height of 5 ft. or so, and the flowers, rather larger individually than in *B. Darwinii*, for instance, are pale yellow. The variety *latifolia* is not only broader leaved, but is a larger-growing shrub altogether, attaining a height of 10 ft. or more. It may be told from the typical plant by the fact that the foliage is green beneath, whereas in the typical plant the leaves are a pale glaucous hue. *B. H. latifolia* is usually called *B. Knightii* in gardens and nurseries.

Somewhat like the above species in appearance but with narrower foliage, golden yellow

flowers, and reddish petioles and sepals is *B. sanguinea*. This is a more elegant shrub than those just mentioned; the branches are less crowded and the whole shrub more pleasing. *B. acuminata* with brownish flowers and large foliage forms a distinguished-looking shrub.

Remarkable among the deciduous species is *B. aristata*, which appears to be quite hardy. It is a rapid and big grower, with rather large leaves often whitish beneath. The flowers are fairly freely produced and good bright yellow in colour. Like most of the deciduous kinds, it is even more remarkable when in fruit. The berries are red, but are covered with a bluish white bloom. There are several slightly differing forms or varieties in cultivation. It is in any form a worthy shrub. Somewhat similar in appearance, though distinct botanically, is the probably smaller-growing *B. pruinosa*.

Equally large-growing but more erect habited is the common Barberry, *B. vulgaris*, an indigenous species with moderately showy yellow flowers in pendent racemes and in autumn quantities of deep coral berries. There are several varieties, but the only one worthy of notice is the purple-leaved form. This is smaller habited than the type, but is none the less very robust. It flowers and fruits freely, and may be considered one of the indispensable Barberries.

Very similar in foliage and habit, but on a smaller scale, is the buff-flowered *B. Thunbergii*, chiefly remarkable for its bright red fruits and, above all, for its wonderful autumnal colour. This, again, has several varieties, but one alone is noteworthy, namely, *B. T. minor*, which

GOLDEN SHOWERS OF BERBERIS STENOPHYLLA.

THE MAHONIA, BERBERIS AQUIFOLIUM.

GORGEOUSLY COLOURED, BERBERIS DARWINII.

grows 2ft. or so tall and has smaller leaves and flowers.

Berberis yunnanensis is a much newer introduction with soft yellow flowers. Growing perhaps 6ft. tall, it has exceptionally large fruits and flowers. Its foliage colours wonderfully in autumn. Another and smaller species with red berries and excellent autumn colour is *B. dictyophylla*.

The foregoing may be taken as typical of a very distinct class of Barberry. Those next to be mentioned, though also deciduous, are quite distinct in general appearance, inasmuch as the shoots are, generally speaking, more slender in proportion to their length and more thickly armed with prickles, while the very numerous fruits are borne in compact masses. Most of these are rather on the small side, but *B. polyantha* reaches a height of 8ft. or more. Its flowers are yellow and produced in long, drooping panicles when most Barberries are over, but it is chiefly noteworthy for the quantities of red berries which hang until late in winter.

B. Wilsonæ has salmon red, semi-translucent berries, and though obviously belonging to the same section as *B. polyantha*, differs from that species very widely. It is spreading in habit, whereas *B. polyantha* is, on the whole, erect growing and it is at all points a smaller and more delicate plant. The crowded flowers are lemon yellow in colour, but are interesting rather than conspicuous. The berries are, of course, the chief attraction, but winter or summer this is always a charming little shrub. It is small enough to be valuable for the large rock garden. In brief notes such as these *B. subcaulalata* may allowably be described as an erect-growing *B. Wilsonæ*. Very close to *B. subcaulalata* is *B. Stapfiana*. Somewhat similar, again, but larger habited and with bloom-covered darker fruits is *B. brevipaniculata* and the closely allied *B. Prattii*. Last of all, we come to the large-leaved Barberries, which gardeners agree to call Mahonias. These Mahonia forms are as distinct from the ordinary run of Barberries as are the Azaleas from the remainder of the genus *Rhododendron*.

The common Mahonia (*B. Aquifolium*) is almost too well known to need description, but its large pinnate leaves, soft green in spring, black-green in late summer, and often gorgeously tinged with red and orange in autumn, are peculiarly handsome, nor are the erect racemes of golden yellow flowers to be overlooked. The violet-coloured berries are very abundantly produced. There are several selected forms or varieties. This accommodating shrub will succeed on dry banks where little else will. It is valuable as a setting for shrubs which flower in winter before their leaves expand—*Forsythia*, to wit, or *Hamamelis*. It is, incidentally, a valuable covert plant. Closely allied is the American *B. repens*, a dwarfer plant with dull, bluish green foliage and less beautiful. The tallest of the Mahonias is *B. pinnata* with more erectly held foliage of a duller green and flowering from the axils down the stem as well as at the tips. The common Mahonia sometimes does this, but less frequently.

B. japonica is a very large-leaved species with dark but not glossy foliage and lemon yellow, fragrant flowers in racemes 6ins. or more long. Very similar, at any rate to the layman, is *B. nepalensis*. A form of *B. japonica* called *Bealei* (*Berberis Bealei*, *Carrière*) is more handsome than either species and hardier. Though most beautiful, even this should be treated with respect and given a sheltered corner. Other interesting Mahonias include *B. trifoliolata*, *B. Fortunei* and *B. Fremontii*, but as these will stand out-doors only in very sheltered situations, little need be said about them.

THE USES OF MATERIAL

II.—SPRING FLOWERING BULBS IN THE WILD GARDEN

THE notes on the uses of Rhododendrons and Azaleas published under this heading a fortnight ago were obviously incomplete, and will at a later date need elaboration. In dealing with a genus like the Rhododendron it would be folly to assume that all that is necessary has been said when a general indication has been given as to the best and most attractive methods of growing what, after all, is only the more decorative section of the genus as cultivated to-day. Outside the garden hybrids is a large and ever-increasing collection of species, some old and well known in gardens, some new and of which much has yet to be learnt, even by those who know them best. These include many alpine species quite unsuitable for the conditions previously described and many Himalayan and Chinese species, some of which are, while others are not, suitable for the same conditions. Occasion will, however, arise for suggesting the most picturesque methods of cultivating these at a later date. To-day my inclination turns to some

SPRING-FLOWERING BULBS AND WILD GARDENS.

Circumstances compel it. I have recently seen some of the fairest pictures of which the English flower garden is capable. Here is one. It is one of those days on which the far-off sky is intensely blue. Miles below the blue, but miles above the earth, roll billowy masses of grey and white cloud. You know the sort of day! One moment the world is grey and dull, the stirring breeze chill and unkind. The next a flood of sunlight sweeps over the scene, and everything seems touched to new and joyous life. It was in one of the grey moments that I arrived at the old Yew tree. Solid, dark and brown, its trunk rose 12ft. to 15ft., and then stretched its branches outwards and downwards until they swept the ground. Under the arching limbs the shadows lay cold and dull, but beyond, in the light, there rippled a greyish blue haze that seemed to go on and on until lost in misty indefiniteness. Then came the sunshine, and the grey became blue, revealing myriads of quivering blossoms of Anemone

apennina. Nothing rigid or formal in this picture, just the sort of thing Nature will do when left to herself. Away from the eye they stretched, first a mass of a million or so all nodding to the wind, then a break and something dark inter-vened, felt but not seen, and yet another sweeping, rippling mass of Anemone, another contrast, and yet a third sheet of sky blue colour and so on. As a picture exquisite in itself, but the glory of the garden is that its joys do not end with the picture so seen. The mind is carried out and away to some transient expression of Nature's beauty that such a scene urges to remembrance. Scudding cloud, a dark foam-flecked sea, and as the moon breaks through in half a dozen silver sheets it touches the restless surface to seething scintillation, and varied and wondrous colour. Such was the thought that passed through my mind as I stood in the sombre shadow of the Yew tree and looked towards the light.

But the Anemones are only part of the garden. A few steps along a gently bending path and another scene breaks on the view. Again blue is the predominating colour, but this time not all blue. Moreover, it is a different blue, that of the Grape Hyacinth, *Muscari conicum* "Heavenly Blue." Broad sheets of azure, cobalt and the greyest of grey blues mingled with cream and yellow *Munstead Primroses* clothe the ground, wave after wave, until the farthest wash is lost in the cream and pale yellow of scattered *Narcissi*. The brown remains of all that is left of last autumn's leaves, tussocks of short grass, late

mown, but now responding to the call of spring with a shimmer of soft green, the dark boles of trees rising sheer from the blue mass, and the lacy pattern of light and shade cast by their branches all combine to create a scene of sensuous delight.

There are other colour effects, too. Golden billows of *Daffodils* that, like a spent wave on

APENNINE ANEMONES IN THE SPRING GARDEN AT HALLINGBURY PLACE.

the seashore, have scattered spindrifts of colour beyond the main mass and so redeem the scene from that abruptness that is too often the failure of these woodland plantings. This is a very important consideration whenever one is contemplating what is understood by wild gardening. The crispness or weight of the picture should always be concentrated in the main masses, the intervening spaces mingled and indefinite. "It is necessary in music, when you strike a discord, to let down the ear by an intermediate note or two to the accord again, and many a good experiment, born of good sense, and destined to succeed, fails only because it is offensively sudden."

I cannot tell of all the wonderful things this particular wild garden contains, even of the spring-flowering bulbs. Other Anemones there were. A few lingering flowers of light and dark blue, pink and white, betrayed the presence of what had been glowing sheets of the Greek *Anemone blanda*, and where the shade was deepest and the ground dampest there crept the many forms of the Wood Anemone *A. nemorosa*. A very short time previously the grass under certain trees had been aglow with *Crocuses*, not only the various garden varieties, but also of the spring-flowering species.

The Glory of the Snow (*Chionodoxa*), both *Luciliae* and *sardensis*, played an important part in the garden a little earlier. Naturalised in masses among low-growing Ferns and in short grass there is no more dramatically thrilling colour than their exquisite blue, that comes well before the winter has passed. Another and different effect, though in no sense less beautiful, is that produced by fallen leaves left from last autumn, ruddy brown in the winter sunlight, through which a myriad Winter Aconites have pushed their golden way, while scattered in drifts through them are Snowdrops. I saw this picture in another garden, too. In this case it was the broad grass stretches on each side of a drive enclosed by an avenue of old Limes. The owner had wisely forbidden his gardeners to remove the autumn leaves, not only from the desire for their colour note in spring, but because it had been

MUSCARI HEAVENLY BLUE AMONG CREAM AND YELLOW PRIMROSES.

proved that the bulbs succeeded much better when the leaves were left than when swept up in the general autumn tidying.

Yet another charm is offered by plantings of the Dog's Tooth Violets (*Erythronium*). Out in the sunlight or where the shadows fall most of the day *Erythronium Dens-canis* will cover the ground with sheets of white, pink and brown, while where the shade is deeper, the undergrowth a little thicker and the ground perhaps a little damper most of the American species will succeed.

If those indicated are not enough, there are still the Scillas, or Wood Hyacinths, with a fine range of colour from the rich blue of the earlier *Squills sibirica* and *bifolia* to the white, rose pink and softer blues of *nutans* and *campanulata*, The North American Wood Lilies (*Trillium*), which desire the moister spots. The Snowflakes (*Leucojum*), and even then the list is not exhausted, but must suffice.

Such gardens are not for all, but something of

their beauty can be produced in a comparatively small area. A few trees, a little care in the preparation and planting, and in particular to the distribution of the various bulbs used, will produce remarkable results at a time of the year when the rest of the garden is still uninteresting.

The spring wild garden is the nearest one ever gets to Nature's soul in the garden. The winter is past, and as the sombre shadows in the woodland grow deeper day by day as the trees put forth their leaves the earth beneath seems to ripple with a multi-coloured smile. Nature's night is over and this is Nature's dawn. Mankind reads day by day the eternal lessons of the universe, hearkens to the "music of the spheres" and sees signs and wonders innumerable, but throughout the year he can find nothing so joyously full of the message of hope, in a world newly redeemed from its winter saddened past, than in the brilliant charm of hollow, dell and hillock in the spring wild garden.

GEO. DILLISTONE.

MANY-HUED COLUMBINES

Their propagation from seed, with some of the better species or strains.

AT this season of the year many hardy perennials may readily be raised from seeds sown in the open garden. Among such few are more worthy than the Columbines, as old-fashioned folk still call the various species and strains of *Aquilegia*. If one has plants of the kind of which it is desired

blossoms. The flowers of this strain are almost invariably of bright but delicate hue, two shades, usually of different colours, being found in each. The petals and spurs are one shade or gradation, though the spurs often take the sepal colour at the tips, and the sepals another. There is an almost infinite variety of colouring.

ALTOGETHER CHARMING—THE BLUE AND CREAMY WHITE BLOSSOMS OF *AQUILEGIA STUARTII*.

to increase the stock, it will, however, be well to wait for the ripening of the seeds. New seeds of *Aquilegia* germinate much more readily, evenly and quickly than those of the previous season.

The old-world Columbines of cottage gardens are forms of *A. vulgaris*, an indigenous plant, and some of them have considerable merit as garden plants, especially the clear blue form and the single and double white ones. There is a strain of these with flatly expanding flowers which is called "Clematis-flowered," though to the writer the blossoms call to mind a large-flowered *Rhodanthe*.

The long-spurred hybrids which are now so popular are derivatives of various American species, all characterised by the long nectar-secreting spurs which assist in giving a fairy lightness to the

Of the species from which these hybrids have originated, the most delicately beautiful is the Rocky Mountain Columbine, *Aquilegia cœrulea*. Petals and spurs of this species are a wonderful semi-transparent pale blue and the corolla white. Others readily procurable are *A.A. chrysantha*, a very long spurred kind with golden yellow flowers; *Skinneri*, orange-red and greenish-yellow; *canadensis*, red and yellow; and *truncata* (*californica*), a long, narrow flower, vermilion without, clear yellow within.

There are many really beautiful old world species, including *A. alpina*, surely one of the most beautiful of alpine treasures. This deep blue and azure treasure is, unfortunately, a biennial and can never be seen at its best if procured as a stunted pot plant

Seed should be sown where it is to flower on a site in the rock garden, not too parched by summer sun. It will then reach 1½ ft. in height and produce quantities of blooms on each plant. It self-sows itself readily enough, but alas! the seedlings almost invariably prove to be worthless mongrels. Collected seed alone may be relied upon, but this may be obtained cheaply enough. *Verb sap.*

Aquilegia glandulosa is a beautiful dwarf species seldom seen true in gardens. The flowers are pale blue with a white corolla. Another treasure with almost disproportionately large flowers for the size of the plants is illustrated. This is *A. Stuartii*, also dressed in bright blue and white. Except, it may be, for a few forms of *A. vulgaris*, it seems well-nigh impossible for a Columbine to be ugly or displeasing. The slender wiry stem and cool, prettily disposed foliage go far to make the veriest mongrel which ever comes up in garden a joy to the eye. It is none the less annoying to find a patch of what was fondly expected to be *A. Stuartii* for instance, a heterogeneous collection with varying shades and shapes of flower and diverse habits of growth. If one would save one's own seed, a plant or two in pots in a carefully screened and isolated cold frame provide the only way of securing the true species, but artificial pollination must, of course, be undertaken.

Freshly gathered seed may, if well soaked, germinate any time from ten days to a month after sowing. It is wise to water thoroughly immediately the seed is sown and cover the drill with a board which should be removed for inspection every day or so after the first ten days. Year-old seed, even if kept thoroughly wet, sometimes takes some time to germinate.

THE ROCK CRESSES

SURELY the most popular plant for the rock garden is the well named Rock Cress (*Aubrieta*). Its ease of culture in any not over-rich soil, its spreading habit, its freedom of flowering and its considerable colour-range are strong points in its favour. So accommodating is it that it will succeed and prove most effective in the front of the herbaceous border or shrubbery; or it may be, and often is, used in spring bedding.

For spring bedding there is no variety so good as the old soft mauve variety *græca*, while *Dr. Mules* is an excellent purple sort for the purposer. *Græca* is especially valuable for ribbon bedding, as, by judicious pruning, it can be kept accurately to shape. For the rockery there are many excellent named varieties, of which the following represent only a personal selection: Among violet and purple sorts, *Lloyd Edwards* and *Dr. Mules*, taking habit into consideration, may have preference. Of mauve and lilac tints, *J. S. Baker* (early-flowering), *Lavender* and *græca* deserve mention. Approaching white there are *tauricola alba* (palest lavender) and *Bridesmaid* (soft blush pink). Of soft rose shades, *Lilac Queen* and *Moerheimi* are good. *Fire King* and *Dandy* are representative of deep ruddy shades. Two variegated leaved forms are both extremely effective, though they are rather sparse in flower. These are called *argentea variegata* and *aurea variegata* respectively, of which the latter is the stronger grower.

For those who have a fondness for raising plants from seed, the *Aubrieta* offers great opportunities, since in a whole batch of seedlings it is usually impossible to find one quite unworthy. The seeds may be raised in a pan at practically any season of the year, and if pricked out as soon as large enough and given ordinary attention will flower in from nine to fifteen months.

It is quite practicable to sow the seeds on old walls, so that they may establish themselves there; but if mixed seed be used it will probably be necessary to discard some, because their colouring clashes with the surrounding varieties. The *Aubrietias* run naturally in shades of more

or less diluted purple, and the reddish tones are apt badly to clash with the bluish ones.

Propagation of named kinds is most readily effected a few weeks after flowering. The new growths from the centre may then be detached with a modicum of root attached and be planted

out under a handlight. Many gardeners cut over the plants immediately flowering is done to facilitate the production of new growths, but should the weather prove hot and dry this custom not infrequently leads to loss of the plants.

FURTHER GLEANINGS FROM CHELSEA

Being the remaining instalment of our Special Correspondents' Comments upon the Exhibits, with Descriptions of the Novelties and Rareties on view.

TREES AND SHRUBS

As ever it was the brilliantly handsome *Rhododendrons* and *Azaleas* that compelled the most attention and admiration at Chelsea. The large, roundish bed filled almost to overflowing with the beautiful pink trusses of *Alice* in one of the many exhibits by Messrs. Waterer, Sons and Crisp was a sight to remember for many a day. This variety is of a darker shade than the popular *Pink Pearl*, which was also present in generous quantity, and the trusses were nearly as large. Another good pink *Rhododendron* in the same exhibit was *Bernard Crisp*, which is a pale blush with deeper-coloured margins. For wealth of bloom it was the immense bushes of *George Hardy* that one admired, and

many *Mollis*, the flame-coloured varieties *Anthony Koster*, a rich yellow, and *J. C. van Tol* were wonderfully beautiful. The little *Kurume Azaleas* are dainty and charming, and were to be seen in the *Yokohama Nursery* collection of stunted trees, in Mr. R. C. Notcutt's exhibit of valuable trees and shrubs, as well as in Messrs. Cuthbert's collection.

Next to the *Rhododendrons* and *Azaleas* came the magnificent *Clematises* by Messrs. G. Jackman and Son. The *Woking* nurserymen have long been famed for the excellence of their *Clematises*, but on the present occasion they excelled themselves. Besides such standard sorts as *Fairy Queen*, *Nelly Moser*, *Lord Neville*, *Lady Caroline Nevill*, *Duchess of Edinburgh*, *Lasurstern*

and by Messrs. R. Gill and Son from the West Country. These included beautiful forms and hybrids of *R. Aucklandii*; and *Lady Aberconway* had the small-flowered *R. Roylei*, *R. Sargentiana* and the fragrant *Lady Alice Fitzwilliam*.

Of general trees and shrubs, though there was not perhaps the usual variety, ample were there to occupy the attention of all lovers of them. The necessity for trees and shrubs, even in the smallest garden, is becoming more fully realised than has been the case in the past. Flowers are necessarily of comparatively brief duration, but prolonged colour combined with grace and charm of foliage is provided by many of the Japanese *Maples*, which were a great feature of the Show. Messrs. W. Fromow and Co. had their usual

MESSRS. WATERER'S EXHIBIT OF RHODODENDRONS.

wondered how it became possible to transport these huge specimens in such excellent order. *Corona* was a charming though smaller truss. The buds are cardinal red, and as they open the colour fades through pink to blush. *Starfish* has a large truss of deep blush pink flowers from which the filaments protrude to an unusual length.

But *Pink Pearl* was the *Rhododendron* of the Show, and besides the large quantity in Messrs. Waterer's collection it was also well shown in the tents by Messrs. J. Cheal and Sons, Messrs. Fletcher Brothers, Mr. G. Reuthe, and in several of the excellent gardens out of doors, as well as in Messrs. Wallace's wonderful *Iris* garden.

Ghent, *Mollis* and *Rustica Azaleas* provided most brilliant masses of colour in many exhibits, though the largest was by Messrs. R. and G. Cuthbert. The double pink *Aida* and the blush *Rosetta* of the Ghent sorts were splendid. Of the

and *Gloire de St. Julien*, they had several splendid new sorts. *Lady Betty Balfour*, a very free-flowering, vigorous, rich velvety purple, which may be termed an immensely improved *Jackmani*; *Crimson King*, which surpasses *Ville de Lyon*; *King of the Belgians*, a silvery mauve of patens type; and *Miss Bateman*, another patens type of pinkish lavender colour, are all splendid acquisitions. Of the double-flowered sorts Mr. Jackman kindly selected for us the best in his opinion. *Belle of Woking*, pale lavender; *Duchess of Edinburgh*, white; and *Lady Lovelace*, pale purple. Good *Clematises* were also to be seen in a collection by Messrs. John Peed and Son, which included *Marcel Moser*, *Lady Caroline Nevill*, *Mrs. George Jackman* and *Duke of Norfolk*, among many others.

The more tender *Rhododendrons* were shown by *Lady Aberconway* from her North Wales garden

large collection in which was to be seen the rich golden colour of *Acer japonicum aureum* contrasting with the intense blood crimson of *A. palmatum sanguineum*. The season has suited all these *Maples*, and they were of even better colour than usual. Their value in association with other shrubs was well illustrated by Messrs. Cheal and Sons, Mr. J. C. Allgrove, Messrs. Wallace and Co. and Mr. R. C. Notcutt, but the most charming colour was on a little specimen of *Acer Chisio* in the valuable collection of rare trees and shrubs by the Donard Nursery Company. Their central mass of the new Donard Seedling *Broom* was also perfectly charming. Such uncommon shrubs as *Lomatia pinnatifolia*, many *Leptospermums* and the variegated *Myrtle* were also included.

Lilacs have had a trying time, but still Mr. Charles Turner, Mr. Notcutt and Mr. J. C. Allgrove were able to exhibit fascinating sprays of fragrant

bloom. With the last-named collection there was a gorgeous spray of *Cornus florida rubra* which retains its bright colour for a long time in a cut state.

A large circle of Hydrangeas of many sorts shown by Mr. H. J. Jones illustrated how handsome this shrub is where it can be grown out of doors. Of his many sorts the rich pink of *Etincelant* and Professor Du Bois was admirable.

Probably the most striking of the trees and shrubs were the large branches of *Davidia involu-crata* in the collection of Mr. J. C. Allgrove. This *Davidia* is the tree which is such a noteworthy feature of the hillsides in Eastern China. It was discovered by the late Abbé David, in whose honour it is named. The tall trees in full bloom, bearing the large twin bracts of almost pure whiteness, give the trees the appearance of having been caught by a late spring snowfall. The true flowers, set in the centre of the inflorescence, are comparatively inconspicuous, but these large white bracts persist for a considerable time. Even before it reaches flowering size the large deep green entire leaves make it a handsome and desirable deciduous tree, which is quite hardy in the Southern Counties.

Out of doors topiary specimens were a great feature. Mr. J. Klinkert had made quite a garden with many of his well grown specimens. The broad grass walks bordered by hundreds of *Nepeta Mussini* gave a cool and restful effect. Almost every possible form was to be seen, and all were perfectly trained. A little further away Cutbush's "cut-bushes" were exhibited, and they were also worthy of admiration for the long, patient skill that had been expended on them. Some very large specimens were arranged by Messrs. Cheal and Sons next to their beautiful Rose garden. In the tent the Yokohama Nursery Company were showing the dwarf Japanese trees which fascinated many visitors.

HARDY PLANTS

One could have spent a whole day wandering from one group of hardy plants to another, taking notes from each of anything that specially appealed. In what group was there not some flower one would fain see oftener and have for one's own as part of the make-up of his garden?

Mr. Amos Perry, as usual, showed many things that attract. Perhaps the gem of his exhibit was a tiny lilaceous plant from the East, garnered by the late Mr. Farrer in high altitudes and called *Nomocharis pardanthina* (var. *Farrerii*). The single flower was very choice, almost orchid-like and was the only specimen in the Show. *Dianthus Fosteri*, a single carmine flower with a peculiar lead-blue centre, is also a scarce plant. It was raised by that eminent Iris grower, the late Sir Michael Foster. Perry's Oriental Poppies are deservedly famous and one admired the variety named after Mr. E. A. Bowles, a dainty and delicate shade of pale pink. Dwarf cushions of golden yellow were formed by *Potentilla aurea*, while that charming but difficult moraine plant, *Lewisia Howelli* made a cool carpet of apricot buff.

In Messrs. Barr's stand one noted the peculiarly shaded Iris *Zwanenburg*, and the *Regelio-Cyclus* *Charon*. *Trollius* in variety gave fine gold and orange effects among the host of well grown herbaceous plants.

From Liverpool came Messrs. Bees, Limited, with long-spurred *Aquilegas*, *Pyrethrums*, *Gentians*, *Polyanthus Beesiana*, and *Meconopsis cambriaca* fl. pl.

Messrs. G. and A. Clark secured a good floor space which they put to profitable use. In the centre *Astilbe Venus* in tall pink plumes dominated groups of *Delphiniums*, *Pyrethrums*,

Eremuri and *Irises*, and there was an uncommonly select strain of *Anemone coronaria* staged along the margins.

Messrs. Wallace and Co., Limited, had a low walled border surrounding their elevated display of *Irises*, and here they had reserved space for various forms of the *Regelio-Cyclus* *Irises*, some

A GLIMPSE OF ONE OF THE TWIN GARDENS OF ALLWOODII.

rather uncommon bulbous plants, such as *Ixiolirion Pallasii* and *Brodiaea coccinea*, and a few of the choicer Lilies, notably *Marhan* (a little gem), *Mrs. R. O. Backhouse*, *Excelsum* and *Regale*. One seldom sees plants of *Myosotidium nobile*, the giant Forget-me-not from the Chatham Islands since the late Mr. Douglas of Bookham brought his giant plants up to the R.H.S. hall twelve and fifteen years ago, but Messrs. Wallace had a few here, so also had Mr. Reuthe of Keston.

One always looks to Messrs. Blackmore and Langdon for *Delphiniums de luxe*, but this year the season has been backward and only a few spikes towered above the magnificent carpet of Oriental colours formed by the firm's collection of *Begonias*; among them were *Mrs. A. J. Watson*, *Capri*, *Lamartin*, *W. T. Ware*, and the new *Mrs. Towle* *Parker*, of lovely sky blue in large single flowers well placed on the spike.

From the well known nurseries of Messrs. Jackman of Woking, came a few showy *Cistus*es well worth seeing. *Silver Rose*, is self descriptive, with very large flowers, while the older forms, *purpurea* and *formosus* were also represented. A new seedling *Lupin* of rich pink shade blended well with *Delphiniums* and tall bearded *Irises*. Among the dwarfier plants, *Aster alpinus* Baker's variety, *Cheiranthus Pamela* Pershouse (pale orange), and *Phlox subulata* *Violet Queen*, stood out prominently.

Messrs. Waterer, Son and Crisp also staged hybrid *Lupins*, *Eureka*, *Sunshine*, and *Moerheimi* being very fine; the old *Iris germanica* grouped in a mass made a fine splash of dark blue. *Iris Alcazar* and *Ingleborg* among the newer hybrids showed the contrast between old and new. *Aster alpinus* *Wargrave* variety is very pretty lavender with a yellow centre. This firm's long spurred *Aquilegas* were noteworthy.

Among a fine lot of hardy *Primulas* and annual *Delphiniums*, Messrs. Piper had a pretty little *Dianthus* named *Ruy Blas*, rather uncommon.

We have seldom seen such robust and highly coloured spikes of *Lupinus hybridus* as those shown by Mr. Downes of Chichester. Such variety of shading and the richness of the tones brings this plant up to a high standard of usefulness for the herbaceous border.

Reading is an important centre for horticulture,

and a new race of very striking hybrid *Mimulus* displayed by the Chalk Hill Nurseries will further fix the name of Reading in the public mind. The plants formed a glorious splash of colour.

VIOLAS AND PANSIES

Exhibition *Violas* largely—so useless for garden embellishment—were shown by H. Clarke, Taunton. The flowers were set up in such a manner that it was difficult to appreciate them. Notable sorts were *Major Townsend* (yellow, edged blue), *Lily Stark* (fancy), *Mrs. James Scalley* (white, edged blue). The better bedding sorts were *Moseley Perfection* (rich yellow), *W. H. Woodgate* (pale blue), *White Empress* (cream), *Swan* (white), and *Maggie Mott* (mauve blue).

Pansies and *Violas* were shown by Mr. John Forbes of Hawick. Quite a number of old favourites were to be seen here, but put up in a fashion too crowded for one to appreciate their true beauty.

In Messrs. Jarman and Co.'s stand were a few *Violas* such as *V. gracilis* *Golden Spur* (sweet scented), *V. gracilis* *Velvet Queen*, and *V. cornuta* *purpurea* in excellent form.

Pansy *Pansies* were shown in fresh condition and in good form by the Chalk Hill Nurseries, Ltd, Reading. Here were to be seen these popular flowers in typical form and in a great array of colour, and the visitors much admired them.

ALPINE AND ROCK PLANTS

Among many exhibits wholly or partially devoted to alpine and plants for the rock garden, one stood out for its exceptional interest to alpine lovers. This was Dr. MacWatt's collection of hardy *Primulas*. One is tempted to enlarge upon the characteristics of each species in a way hardly admissible in a show report. Of the better-known species on view, such as *Bulleyana* and *helodoxa*, there is little need to speak, though

a group of *P. sikkimensis* was worthy of notice for the truly remarkable health and vigour of the plants exhibited. Evidently related to this species, the seldom-seen *P. chionantha* with creamy white blossoms and foliage smoother than in *P. sikkimensis* claimed attention, but though excellently grown, it lacks in our climate the vigour of the Sikkim plant.

The *Primula Veitchii* were remarkable for the richness of their colour, being evidently the result of much careful selection. Others of the cortusoides section displayed were the very distinct *P. geraniifolia*, and that beautiful and interesting species *P. seclusa* with wonderful foliage and striking dark-centred starry flowers. The beautiful and substantial-flowered *P. lichiangensis* with its deep brown calyces, however, we looked for in vain.

P. involucrata was there looking, as usual, rather washed-out by day, though it shows bright enough at dusk; also *P. Wardii*, very similar to *P. involucrata* in habit, but deeper in colour. The variable and also similar *P. sibirica* was not included, though we noticed it elsewhere in the Show.

Those two striking if very dissimilar species—neither good garden plants—*P. P. Littoniana* and *Forrestii* were there, and quite a collection of species more or less in the way of *P. muscarioides*, including such seldom-seen species as *P. P. nutans*, *Watsoni*, *conica* and *Menziesiana*, also *P. capitata* (true).

Of the *farinosa* section a fine plant of *P. longiflora* was noticeable, but *P. farinosa* itself was on view, as were *P. P. saxatilis* and *fasciculata*, both uncommon, though the latter has recently received an award of merit.

Other beautiful species noted were *P. P. secundiflora*, *Wilsoni*, *Smithiana*, *Rusbyi*, *Readii*, *Werringtonensis*, *heucherifolia* and the charming *vincaeflora*. Of the various cross-breeds space will allow reference only to the hybrids between *P. marginata* and border *Auriculas*. These were exceedingly charming and are doubtless easy garden plants.

Those who go to an exhibit staged by Mr. G. Reuthe to look for rare and beautiful plants are never disappointed. His display at Chelsea, though greatly curtailed by the "Powers that be," was a veritable mine of interest. A small collection of hardy British Orchises first claimed attention. It is strange these are not more sought after, since many of them are at once distinguished and beautiful. Here were, among others, *mascula*, *pallens*, *fusca*, *undulatifolia* and *latifolia*—a form from Kilmarnock this. In another part of the exhibit was to be found the beautiful Colombian Orchis, *O. spectabilis*. A good and substantial variety of *Primula Sieboldi* was noted, but it occasioned a pang of regret that most of the range of these Japanese Primroses seem to have dropped out of cultivation. *Dianthus musale* appeared to be identical with *D. microlepis* var. *rumelica* noted elsewhere. Whichever name (if either) be correct, this is a pleasing and compact little Pink obviously related to *D. D. microlepis* and *Freyii*, but easier to grow than either. Other treasures noted were *Ramondia pyrenaica alba*, *Haberlea virginialis*—at the risk of being thought heretical the writer will hazard that this is the only *Haberlea* worth cultivating—*Androsace glacialis* (a very pale form), *Geum triflorum*, *Linum capitatum*, *Daphne Valloti* (true) which flowers several times a year, the purplish *Cheiranthus limbiloba*, *Myosotis Ruth Fischer*, the seldom-seen *Anemone globosa* with smallish rosy carnine flowers, *Polygala Chamabuxus Vagredæ* (the Spanish form, which is a brilliant carnine externally), and several sorts of Wood Lily, including the purplish *Trillium sessile californicum erectum* (thank you!) and *T. rubrum grandiflorum*.

On Mr. Hemsley's exhibit *Wahlenbergia serpyllifolia* was noteworthy, also *Antirrhinum Asarina* and *Heeria elegans*. A plant labelled *Dianthus Freyii nana* was quite beautiful, but approximated very closely to *D. microlepis* var. *rumelica* as exhibited elsewhere. *Dianthus neglectus* was good in colour but starry in form.

The rockery bank (on staging) of Mr. E. Scaplehorn of Lindfield was chiefly remarkable for a nice collection of dwarf conifers, among which the trailing *Thuya Sargentii pendula* called for special notice. A nice piece of that delightful carpeter *Raoulia australis* served as a foil to the flowering plants, while a little colony of *Saxifraga lantoscana* was the too usual dirty white, not the glorious pearly form which represents the perfection of beauty in encrusted Saxifrages. The vivid colour of *Tritonia aurantiaca* attracted much attention.

Messrs. W. H. Rogers and Son of Southampton had an exhibit of considerable interest, featuring House Leeks (*Sempervivums*) rather largely. Other worthy things noted were a wee Cypress, *Cupressus obtusa tetragona minima*, *Asplenium Trichomanes* in very healthy condition, *Helichrysum bellidioides*, *Oxalis enneaphylla*, *Linaria pallida rosea* and *Sisyrinchium pachyrrhiza*, healthy and interesting, but not yet in flower.

Mr. Maurice Prichard had the "Mother o' Thousands"-like *Saxifraga Brunoniana*, the bright *Silene Hookeri*, *Erodium chamædryoides rosea* (a dinky little Cranesbill), that azure *Forget-me-not*,

including *C. C. parviflorum* and *montanum*, *Haberlea Ferdinandi Coburgi*, *Linaria Cymbalaria alba compacta*, which really seems compact in habit and tree to flower, and two hybrid Pinks called *Mona* and *Adoree*, which may both be described as long-stemmed, large-flowered and exquisitely shaped forms of *Dianthus neglectus*.

On Messrs. Waterer, Sons and Crisp's stand a nice colony of *Dodocatheons* were attractive. Other good things included *Viola pedata*, *Cheiranthus alpinus citrinus* and *Cytisus Ardoini*.

Messrs. Cheal's exhibit had for its most noticeable feature the beautiful *Asteriscus maritimus*, but this, of course, is hardy only in favoured localities, and even then needs a sunny corner. *Oxalis adenophylla*, *Pentstemon Scouleri*, *Androsace villosa* and the monocarpous *Sedum pilosum* were also noted, also the graceful hardy Maiden-hair, *Adiantum pedatum*. The form of this exhibited was very beautiful, but scarcely typical of the species.

Messrs. Bakers of Wolverhampton had a lot of furnishing plants, including such beautiful things as *Pentstemon Scouleri*, *Androsace z. Chumbyi* and *Gentiana verna*; the Chalk Hill Nurseries of Reading had large-flowered *Mimulus*, which would be ideal for the bog; while Messrs. Bees had an interesting exhibit which included *Androsace Watkinsii*, *Trillium grandiflorum*, *Saxifraga lingulata* and the Warley *Æthionema*.

THE BRIGHT ROSY-CERISE DIANTHUS ALPINUS.

Myosotis rupicola, *Anemone sylvestris* and *Primula Ailni Aroon*. This was to be seen throughout the Show, but the plants of Mr. Prichard looked unforced and characteristic of the variety. Other noteworthy plants from the Christchurch nurseries included *Anemone sylvestris* and *A. baicalense* (very pretty and uncommon), *Gazania montana*, *Ranunculus bilobus*, *Oxalis adenophylla*, *Lewisia Howelli*, *Delphinium nudicaule luteum* (strange in its yellow livery), *Primula capitata*, *Potentilla verna nana*, hardy Slipper Orchids of sorts, mainly *Cypripedium pubescens*, but

Mr. F. G. Wood of Ashted, Surrey, had an interesting little exhibit with such things as *Onosma tauricum*, *Aquilegia glandulosa*, *Sedum dasyphyllum* and *Dianthus deltoides* Brilliant.

Those in search of the uncommon were well catered for by Mr. Reginald M. Prichard of West Moors, Dorset, whose commoner things (!) included *Gazania splendens* and *G. montana*, *Dianthus alpinus*, *Cotyledon sinplifolia* and *Helichrysum frigidum*. A brace of singular and rare *Androsaces* were the brick red "Chinaman," *A. coccinea*, its flower umbel on a 6m. stem, the rosette of

leaves dark green and hairless, and the extraordinarily foliaged *A. geranifolia* with especially long, wiry stems and flower-heads something like those of *A. sarmentosa*. *A. foliosa* also was noted.

The pale purple *Campanula Aucheri*, obviously an easy doer, but with rather a *Wahlenbergia* appearance, was also noteworthy. *Phlox Douglasii* Lilac Queen is obviously a cross between *P. Douglasii* and a *P. setacea* form. It will become popular. *Phlox subulata* Alicar is a lilac seedling from Nelson, whose fine habit it retains.

Messrs. Tucker of Oxford had an exhibit indoors, where *Lewisia Howellii*, *Cyclamen repandum*, *Androsace Watkinsii* and *A. Chumbyi*, *Wahlenbergia pumilio* and *Atragene alpina* were noted. Both here and on their rock garden outside *Dianthus microlepis rumelicus* was in evidence. Outside, *Dianthus alpinus* and the white variety, *Myosotis rupicola*, *Sedum pilosum*, *Matthiola pedemontana* (a grey-blue alpine Stock), *Primulas farinosa* and *frondosa*, *Arnica montana*, *Orob. varius*, *Iris lacustris*, *Pinguicula grandiflora* (cool as cool in its damp, shaded corner), *Allium pedemontanum* and *Orchis fusca* were some of the treasures on view.

Messrs. Skelton and Kirby's exhibit was noteworthy for good patches of *Aizoon Saxifragae*, *Olearia stellulata*, a valuable shrub for the fair-sized rockery, was also represented.

Mr. Ladhams had brought up from Shirley, near Southampton, a collection of hardy plants mostly suitable for the herbaceous border, but *Primula helodoxa*, a wide colour range of *P. japonica*, some nice *Dodocatheons*, the brilliant yellow *Oxalis Valdiviana* and the white Dog-Violet were interesting.

Messrs. Bowell and Skarratt's collection included *Androsace primuloides* (surely more chaste than *A. Chumbyi*, but less often seen), *Corydalis Wilsoni*, *Tulipa persica*, *Cypripedium acaule*, *Antirrhinum Asarina*, *Oxalis adenophylla*, *Potentilla alchemilloides* with handsome foliage and silvery white flowers, *Thalictrum anemonoides* and *Asperula suberosa*. The quaint spotting of *Veronica pectinata rosea* and another *Speedwell* of somewhat similar complexion called *V. circulosa* with tiny white spotted flowers attracted attention.

Mr. Wells, Jun., had a scratch alpine exhibit acting a stop-gap for a collection of herbaceous plants not ready in time. Such excellent plants were included as alpine Poppies in various colours, *Anemone sylvestris*, *Trillium grandiflorum*, some *Ranondias* smothered in buds, but not yet fully in flower, including the rare pink variety and an excellent colour form of *Primula sibirica*.

On Mr. Clarence Elliott's rock garden outside was what he designated an alpine meadow. The idea is that by planting appropriate alpines of various habits thickly together they form a natural turf which quite obviates the need for grasses of any kind, which are quite unsatisfactory in our climate. Mr. Elliott claims to have tried and proved the method of planting. The meadow as exhibited included *Linaria pallida*, *Bells sylvestris*, *Arenaria verna*, *Gentiana verna*, *Kalschia Saxifragae*, *Primula farinosa*, *P. scotica* and the glaucous-foliaged alpine forms of *Senecio Doronium*, *Mongrel Pinks* and *Violas* for the rockery are the writer's pet aversion, but those who like them should make a point of seeing *Viola Arkwright's Red*.

GARDEN DESIGN

In the tent devoted to them and more happily placed this year near the formal gardens, the garden architects displayed their designs and photographs of completed work. Messrs. Milner, son and White made something of a new departure in the form of a scale model of one

of their gardens. This would certainly be easier for many people to understand and appreciate than the usual garden plan, but, though even the camera can be deceptive, photographs of completed gardens provide the "acid test" most people favour. Mr. Percy Cane evidently appreciates this, for his display this time consisted even more largely than usual of excellent photographs of completed gardens in various styles and in excellent taste.

Messrs. Wallace, however, still favour colour-washed perspectives, and colour in the garden is of the highest importance. The cost of colour photography which would combine both advantages is, one supposes, prohibitive.

ORCHIDS

Sir Jeremiah Colman, Bart., exhibited a truly remarkable group of rare species and choice hybrids from his celebrated collection at Gatton Park, Surrey. The finest of the Brasso-Cattleyas was seen in a beautiful pure white flower named *Gatton Lily*; and another hybrid, equally large and rich in colour, was *Laelio-Cattleya J. F. Birbeck*. The back row was made bright with several

Messrs. Charlesworth and Co. staged one of the largest of the trade-growers' groups. It was made light and effective by the massing in the centre and at each end of snow white *Odontoglossum*. The finest plant was unquestionably *Odontoglossum Purple Emperor*, with three immense, heavily blotched purple flowers. A hybrid that attracted much attention was a grand plant of *Brasso-Cattleya heatonensis*, with eight large canary yellow blooms, the lip being deeply fringed at the margin. *Peristeria elata*, known as the Dove Orchid, was well shown. A very curious flower of greenish colour was seen in *Lycaste gigantea*, and a light tinted species was represented by the rare *Vanda snavis pallida*. In the angle of the group many interesting *Cymbidiums* were staged, and it is remarkable that some of these flowers had been open for over six weeks. A hybrid that has remained noteworthy since the old Temple Show days was seen in *Laelio-Cattleya Fascinator*, with rose-coloured petals and a purple lip. *Miltonia vexillaria* and a wide selection of its handsomely blotched hybrids were fine examples of present-day seedling Orchids.

Messrs. Sanders staged an extensive group, the chief attraction being the rare *Ansellia congoensis*,

THE GLORIOUS ODONTOGLOSSUM PURPLE EMPEROR.

plants of the golden yellow *Dendrobium Hlnstre* and superb examples of *D. Dalhousieanum luteum*. One of the features of this group was the rare *Dendrobium acuminatum*, the best plant carrying four spikes with an aggregate of fifty-five rose-coloured blooms. Areas of golden yellow were produced by masses of the graceful *Odontoglossum Wilckeanum Colmanii*, and several finely cultivated *Odontodas* added attractive spots of bright scarlet. A striking Orchid and one of the real rarities of the Show was *Megaclinium purpureorachis*, the minute blooms resembling a row of toads sitting on a flattened snake.

with three spikes and an aggregate of 170 blooms. Near one end was the tall *Cyrtopodium punctatum*, with a fine spike of numerous flowers. A novelty was seen in *Cymbidium Nelly*, with greenish-yellow blooms, and the interesting *Angulocaste Vesta* was staged near by. A beautiful effect was produced by many fine examples of *Cattleya citrina*, the pendulous, globular blooms of rich yellow hanging over a bed of green moss. A noteworthy plant was the albino variety of *Aerides virens*; and a fine example of cultivation existed in *Odontoglossum crispum*, carrying a spike of seventeen crimson-blotched flowers.

NEW AND RARE PLANTS

Messrs. J. and A. McBean had a group containing exceptionally well grown *Odontoglossums*, the best being *O. Arabic*, with a spike of four chocolate-coloured flowers. *O. Lilian*, with seventeen blooms, and a fine variety of *O. Rosina* came in for well merited praise. Along the front row were to be seen fine varieties of *Miltonia vexillaria*, those with blotched lips being well above the average. A richly coloured flower was staged in *Cattleya Empress Frederick*, and several snow white hybrids of this genus were worthy of inspection.

Messrs. Stuart Low and Co. showed the Jarvisbrook variety of *Brasso-Lælio-Cattleya Jupiter*, an immense flower. Another variety of this hybrid, named *His Majesty*, was a gorgeous companion. This firm had also in their group, *Brasso-Cattleya Trium*, with two large purple blooms. Fine *Cattleyas* were seen in several varieties, and a golden-yellow Orchid was represented by *Lælio-Cattleya luminosa aurea*. A fine piece of orange colour was produced by massing *Lælio-Cattleya G. S. Ball*, which is still a favourite hybrid. The *Odontodas* included a striking combination of scarlet blotching on a rose-tinted ground, and named *O. Eileen*. Many interesting *Oncidiums*, some bright yellow *Dendrobiums* and selected varieties of the best known hybrids were admirably staged.

Messrs. Cypher and Sons showed some remarkable plants of *Epidendrum gattouense*, the spikes of which had continued to produce orange-red flowers for over twelve months, and looked like keeping fresh for even longer. No spring show is complete without the ever-moving flowers of *Bulbophyllum barbigerum*, and four unusually fine examples of this species were well staged. The pretty *Oncidium Papilio*, with its butterfly-like blooms poised on tall bending spikes some 3ft. in length, was very pretty, as also was a grand plant of the scarce *Selenipedium macrochilum* with its long ribbon-like petals.

Messrs. Flory and Black included in their neatly arranged exhibit a large *Brasso-Lælio-Cattleya Rumania*, white, with a purple streak on the centre of the lip. A novelty was seen in *Rolfeara Atreus*, and the albino flowers were well represented by *Cattleya Irene* and *C. Brenda*. Mention must also be made of *Lælio-Cattleya S. O. Stephenson*, an improvement on the well known *L.-C. Dominiana*. A new hybrid of much promise was *Lælio-Cattleya S. W. Flory*, with rich rosy-purple flowers.

Messrs. Mansell and Hatcher exhibited a choice assortment of the popular hybrids, mainly consisting of blotched *Miltonais* and pretty varieties of *Lælio-Cattleya Fascinator*, as well as *L.-C. Hyeana*. A plant of more than ordinary interest was *Cypripedium Curtisii Sanderæ*, with emerald-green flowers. Near the centre was to be seen *Lælia purpurata Queen Alexandra*, white, with light rose veining on the lip. A pleasing effect was made by scarlet *Odontodas* placed near some pure white *Odontoglossums*.

Messrs. Armstrong and Brown had an effectively arranged group, in which the central plant was the *Orchidhurst* variety of *Brasso-Cattleya Dietrichiana*, exceptionally well coloured. Among the *Odontodas* was one named *Henryi*, having a spike of twenty-three flowers of an unusual orange-yellow tint. The elegant *Cymbidium Lowgrinum*, as well as *Cypripedium Maudslayi*, with its greenish blooms, were seen to advantage. Several new *Odontoglossum* hybrids were worthy of close attention.

Mr. Harry Dixon staged some excellent *Cattleyas* and *Brasso-Cattleyas*, among the latter being fine forms of *Queen Alexandra* and *Empress of Russia*. The central area of this group was well filled with scarlet *Odontodas* and white *Odontoglossum crispum*, while on either side were some fine varieties of the popular *Cattleya Mendelii*, as well as hybrids of this species and of *C. Mossia*.

Aponogeton distachyon roseum Aldenhamense.—A very vigorous variety of the Water Hawthorn. The floral bracts are faintly flushed with salmon-pink, which is deeper coloured at the base. It is not quite so fragrant as the type, though it is a handsomer water plant. Shown by the Hon. Vicary Gibbs.

Carnation Cream Saffron.—Apparently this is a pale cream-coloured sport from the well known variety of greenhouse Carnation, for it is much

H. Professor du Bois.—This variety produces very big, shapely trusses of large, shining mid-pink-coloured flowers. It was decidedly the best variety in the large collection at the Show. Award of merit to Mr. H. J. Jones.

Iris Regelio-cyclus Crestes.—A fascinating Iris which is much easier to admire than to describe. It has all the grace and charm of this group, which is the result of intercrossing *Iris Regelia* with *Iris Oncocyclus*. The delicately

THE CHARMINGLY COLOURED PARROT TULIP FANTASY.

like it in form and size. Occasionally the creamy-white flowers are touched with yellow. Award of merit to Mr. C. Engelmann.

C. Orangeman.—An excellent Border variety of good shape and orange colouring. Award of merit to Mr. J. Douglas.

C. Steerforth.—A large, well formed Border Carnation. It is heavily flaked and margined with bright crimson on white ground. Award of merit to Mr. J. Douglas.

C. Viceroy.—A very handsome Border Carnation. It is a yellow ground variety, lightly flaked with crimson, shading to purple at the margins. Award of merit to Mr. J. Douglas.

Cytisus Donard Seedling.—In many ways this may be termed a more vigorous and graceful *C. Dallemorei* and of rose and fawn colouring. It is the result of a cross between that variety and *C. ochroleuca* and is a handsome shrub, growing quite 12ft. high. Perhaps the most promising novelty in the Show. Shown by the Donard Nursery Company.

Hydrangea Parsival.—A charming and highly decorative variety. It bears shapely, compact trusses of rich pink-coloured flowers not quite so large as in some sorts, but it makes a good head above medium-sized leaves. The individual flowers are round, flattish and have evenly serrated edges. Award of merit to Messrs. W. H. Cutbush and Son.

veined standards are bronzy-mauve coloured, and the falls are shaded purple lake. The delicate beard is sap-green, and there are twin emerald lines on the style arms. Award of merit to Messrs. Barr and Sons.

Monocharis pardanthina Farreri.—A charming and uncommon little Lily, discovered by the late Mr. Farrer on the grassy slopes of the Hypinaw Pass of the Yunnans. The colour is variable, but generally is silvery shell pink, flushed with rose on the outside. The edges of the flowers are evenly serrated. The plants on view bore only a single bloom, but Mr. Farrer describes it as having two, three or more. Shown by Mr. Amos Perry.

Pelargonium Sir Percy Blakeney.—An "Ivy-leaved Geranium" of unusually compact and sturdy habit. The bright, deep scarlet flowers are produced more freely than is usually the case with this type. Award of merit to the Rev. D. T. Wright.

Pink (Herbertii) Bridesmaid.—A charming little garden Pink of pale blush colour with a much deeper zone. Award of merit to Mr. C. H. Herbert.

P. (Herbertii) Lord Lambourne.—A handsome, velvety carmine border Pink nearly as large as a Carnation. It has crimson-maroon centre and is sweetly scented. Award of merit to Mr. C. H. Herbert.

P. (Herbertii) Red Indian.—An uncommon border Pink of medium size and deep rosy lavender colouring. Award of merit to Mr. C. H. Herbert.

Primula obconica Salmon Queen.—An exceedingly pretty and floriferous variety. It makes a sturdy, compact plant, bearing large numbers of round, salmon-pink flowers of great substance. In general appearance they are much like those of good form of *Primula stellata*. Award of merit to Messrs. Sutton and Sons.

Rhododendron Coalition.—A neat and compact truss of more than medium size. The colour varies from blush-pink to vivid rose-pink and is very attractive. The deep green foliage makes it a handsome bush at all times. Award of merit to Mr. Lionel de Rothschild.

R. Falconeri.—There was shown a wonderfully handsome truss, set above its large, striking, rugose leaves, densely clothed with rust-coloured felt underneath. Unfortunately, this Himalayan species is too tender to produce its large, creamy white floral bells out of doors except in the most favoured places. Award of merit to Messrs. R. Gill and Son.

R. Geoffrey Millais.—A chaste and beautiful flower. The large truss is made up of widely expanded blooms of the faintest blush tinge, which, at times, are quite white. The long style is pale salmon coloured. Award of merit to Mr. Lionel de Rothschild.

R. Norman Gill.—This was the most beautiful of the many Himalayan hybrids at the Show. The truss is very large and quite compact. The almost immense blooms expand widely and are apple blossom blush shades of colour with a small crimson blotch in the centre. Apparently a cross between *Beauty of Tremough* and *R. Aucklandii*. Award of merit to Messrs. R. Gill and Son.

R. orbiculare.—A fair-sized truss of dainty, widely expanded, bell-shaped flowers of ruby-magenta colour. There are distinct veinings of a rather darker shade of this colouring on the flowers. The neat foliage is pale pea green colour underneath. This is apparently one of the many species from China, and would make a very attractive bush of medium size. Award of merit to the Hon. H. D. MacLaren.

R. St. Keverne.—A very handsome truss which appears to owe something to *R. Thomsonii*. The large blooms are of deep crimson colour, and are lightly spotted on the upper segments. Award of merit to Mr. P. D. Williams.

R. Robert Fortune.—A very large truss of charming pale blush colour. The large flowers open widely, disclosing a striking rayed crimson-lake blotch around the style. It is one of the Himalayan hybrids that luxuriate so well in Cornwall. Award of merit to Mr. P. D. Williams.

Rose Capt. F. S. Harvey Cant.—A large, full, H.T. Rose of globular shape, deep pink colour and pleasant fragrance. It is of vigorous habit, and several good standards were on view. Shown by Messrs. Frank Cant and Co.

R. Henry Nevard.—A velvety crimson H.P. Rose, fully double and of flattish shape. It possesses in a marked degree the real old Rose fragrance. The growths are stout and vigorous. Shown by Messrs. Frank Cant and Co.

R. Mrs. F. S. Harvey Cant.—A very large H.T. Rose that in appearance when fully open suggests a larger *Souvenir de la Malmaison*, but it has the Tea Rose scent. Shown by Messrs. F. Cant and Co.

Stellera Chamæjasme.—A very rare little Thyme-like sub-shrub which is rarely seen in

cultivation. It is a neat little plant, about 1 ft. high, bearing small, lanceolate leaves surmounted by rounded heads an inch or so across of creamy, star-like flowers. It is the *Ground Jessamine* of Siberia, and was introduced in 1817. Award of merit to Major Stern.

Tulip Carrara.—This was the first really white Darwin Tulip to be raised, and it received an award of merit last year. It is a vigorous variety, producing large flowers. The petals are broad and the filaments are green. First-class certificate to Messrs. Barr and Sons.

T. Dido.—A very showy Darwin Tulip of soft orange colour. The outsides of the petals are heavily coloured with carmine red. Award of merit to Messrs. Barr and Sons and to Messrs. Dobbie and Co.

T. Phemio.—An excellently shaped white variety with pale green stigma and anthers. Award of merit to Messrs. Barr.

T. Fantasy.—This is an exceedingly beautiful Parrot Tulip of glistening pink colour shaded with orange and pink on the wide ragged petals. The flowers are stained with brownish green on the outsides. It was raised by Messrs. de Graaff Bros. Award of merit to Messrs. Barr and Sons.

Telopea speciosissima.—Several most handsome heads of this rare Australian shrub were shown, and their uncommon shape and bright ruby cardinal colour, shading to crimson, attracted a deal of admiration. It is the *Waratah* or *Warrataw*, and is the national flower of Australia, but is so rare that only a few in that country have seen it. First-class certificate and cultural commendation to the Rev. A. T. Boscawen.

BORDER CARNATION STEERFORTH, BRIGHT CRIMSON-PURPLE AND WHITE.

THREE NEW BORDER PINKS (HERBERTII), BRIDESMAID, RED INDIAN AND LORD LAMBOURNE.

HORTICULTURAL APPLIANCES AND SUNDRIES

After the stifling heat and the heavy scent-laden air of the tents at Chelsea it was a relief to get outside and walk down the Lime Avenue where the horticultural appliances and sundries were to be found. There one could walk in comfort and inspect the varied assortment of garden accessories and labour-saving devices so necessary in these days to the garden owner. Here were to be seen mowing machines of every description, spraying machines, garden furniture, garden ornaments, insecticides and a host of other things.

Messrs. Boulton and Paul had a revolving garden shelter which appealed to many visitors. These shelters are exceedingly useful to those whose gardens are somewhat exposed. Here, too, was a very attractive conservatory, very strongly built and lofty. It would be an ideal structure to adjoin the dwelling house. Excellent garden frames were also on show, and what especially appealed to the writer, the Chain Helice water elevator for deep wells. Easy to work and not expensive, this elevator should appeal to those country readers whose houses are not a network of pipes and with whom inspectors of the Water Board have not yet become so prevalent as white fly.

Near by, Messrs. Duncan, Tucker and Sons, the well known horticultural builders, had some attractive-looking greenhouses, conservatories and garden furniture. Here, too, propagating cases, so essential for the raising of plants, were on view. The up-to-date ventilation system adopted by this firm is very good and easy to work.

Greenhouses were also shown by James Gray, Limited. This firm had also a new flower pot which, made of galvanised iron, is said to be exceedingly useful for the cultivation of Tomatoes under glass. There are no bottoms to these pots, and as they stand on the ground level the plants can root straight into the soil beneath. This method of culture is said to yield splendid crops. Garden frames and Gray's special Tomato fertiliser were also included in the exhibit.

The largely used Acme weatherproof non-rustable garden labels were to be seen on Mr. J. Pinches' stand. A novelty shown here, although simple in design, will no doubt be welcomed by many gardeners. It is, in effect a swivelled pot-hook, the idea of which is for suspending plants either in a greenhouse or porch. The pot-hook is constructed of wire and works on a swivel, thus enabling the gardener readily to turn the pot round and so equalise growth. Mr. Pinches also catered for the exhibitor by showing a new shelf-clip, into which may be fixed vases.

The Improved Pemberton Display Stand which is collapsible and worked on the clamp principle, should prove of great value to the exhibitor. The vases may be placed in any position, which is a great advantage. There were also table stands in various designs for cut flowers.

Messrs. Walter Voss and Co. showed their well known insecticide, fungicides and fertilisers. Here, too, was to be seen cyanide of potassium, the deadly poison so useful for the annihilation of white fly. We understand that this firm have recently taken over "Blighty," the well known wash for Potato disease.

H. Scott and Sons showed a large collection of insecticides and weed killers. The "Alvesco," a fumigant for Tomatoes against the ravages of white fly, was exhibited by Murphy and Son of Mortlake. There was also displayed nicotine petroleum emulsion, said to be extremely effective against red spider on Cucumbers, whilst ammonium copper carbonate for Tomato rust and Gooseberry mildew was also included in this extensive exhibit of insecticides and fumigants.

Jeyes' Sanitary Compounds, Limited, brought their well known horticultural washes and sprays which are familiar to the majority of gardeners.

"Rito," the famous fertiliser, was shown by the Molassine Company. This is a good all-round fertiliser.

From Edward Cook and Co. came a comprehensive collection of insecticides, fungicides, fertilisers and spraying machines.

Messrs. Prentice Brothers exhibited their well known "Tomorite," the Tomato fertiliser. Ichthemic guano and innumerable other fertilisers were also included.

"Prize Crop" fertiliser was the chief exhibit on the stand of Maskell-Harris and Co. We also noted their Alkaline fertiliser.

Fertilisers, insecticides, spraying machines and syringes were shown in an extensive exhibit by the well known Stonehouse Works Company.

"Metro" sulphate of ammonia, creosote, etc., were exhibited by the South Metropolitan Gas Company.

"White Fly Death," sulphur wash for Rose and fruit trees, "Niquas" (Improved), an excellent non-poisonous insecticide, and lawn sands were exhibited by Corry and Co., Limited.

"Sox," the famous non-poisonous insecticide and fungicide, and Dyoweed, a non-arsenical weed-killer were the chief exhibits staged by Messrs. Hawker and Botwood, Limited, who had a host of their other well known and approved insecticides and weed-killers.

Lime preparations were to be seen on the stand of the Buxton Lime Firms Company, Limited.

The popular Abol spraying machines and hand syringes of every description were shown by Abol, Limited. Spraying machines were also shown by the Four Oaks Spraying Machine Company, Limited; Messrs. Edward Cook and Co.; and the United Brassfounders and Engineers, Limited.

Messrs. Cooper, Pegler and Co. showed the popular Vermorel's spraying machines and a host of sprayers for every purpose.

The Automatic Utilities Company showed their Dayton rotary and oscillating sprinklers, which can be made to sprinkle water from a 3ft. to a 40ft. radius. It can be made to sprinkle in a circle or half-circle. It is quite a small affair, very reasonable in price, so it should find a home in every garden. Tennis players particularly should make a point of procuring this excellent little sprinkler. Other types of sprinklers were also shown by this firm, and were in working order, which made one in the tropical heat feel inclined to take a "shower."

Exhibits of garden furniture were numerous. Cane furniture was shown by the Dryad Cane Company. Other firms with exhibits of garden furniture of all designs included Harrods, Messenger and Co., Atlas Wholesale Supply Company, H. and J. Caesar, Abbott Brothers (folding furniture), Village Centres Council (disabled men), Homebilt Company, W. Unwin, Piggott Brothers (who had also tents and tent equipment), Castle's Shipbuilding Company, A. W. Gamage, Limited, Hughes, Bolekow and Co., and Wm. Wood and Son, who, besides, had an extensive exhibit of everything for the garden. Their grey hard tennis court was also on view.

Garden ornaments of every description were on view, and it is impossible here to describe the many beautiful sundials, pieces of statuary, well-heads, fountains and other desirable things. Those who showed the above included Sander and Co., London; Hughes, Bolekow and Co., Kelly and Co., A. H. Moorton, Limited, and Ravenscourt Pottery.

A substitute for glass was shown by C. M. Davies and Co. It is called "Windolite," and is

said to be an excellent thing for greenhouses and frames.

A novelty was exhibited by H. J. G. Wood (H. J. Greenwood) in the shape of a plant stake. It is called the Willmott Rival Plant Stake. Made of galvanised wire, and simple in design, it should prove of exceptional value to those who grow Carnations and bulbs, including Freesias.

Arthur H. Moorton, Limited, had a large display of birds' nesting-boxes. This firm has recently taken over these boxes from the Royal Society for the Protection of Birds.

Ladders of all descriptions were to be found down the avenue. Messrs. Drew, Clark and Co. had a large selection of their "Diamond" ladders, including patent extension ladders.

The Acme Patent Ladder Company also had a large collection of their well known ladders.

House and Garden Sundries Company exhibited their patent seed sower, which is a great boon, especially to the amateur gardener. They also had their wall clips, which are extremely useful for Roses and fruit trees. A new invention just brought out by this firm is for netting supports for the protection of Strawberries. Made of stout galvanised wire, these supports are also useful for dwarf Peas and such like crops. The supports in use were illustrated in our last issue, on page xvi.

Garden Supplies, Limited, had a vast collection of garden accessories, including motor mowing machine, syringes, garden tools, lawn sands, weed-killers, artificial manures and many other things. A new garden roller attracted the writer's attention. Made of concrete, it is heavy and reasonable in price.

W. Carson and Sons had a collection of paints suitable for greenhouses and horticultural buildings generally.

Some fine fibrous yellow turf loam was shown by Mr. A. B. Johnston.

The well known Carnation raisers, Messrs. Allwood Brothers, had a stand containing Carnation supports, rings, labels, fertilisers, and a lot of other indispensable things to the Carnation grower.

Perhaps the greatest novelty in the sundries section was a gardener's tool bench shown by R. Melhuish, Limited. Fitted up with drawers containing labels and all the tools required for the garden, this should, indeed, find a place in every moderate-sized garden. Very compact, it does not take up much room. Other notable things on this stand were seed cabinets, which are essential, especially in large gardens; hand sprayers, mowing machines, insecticides, and every kind of garden tool imaginable.

Mowing machines of all descriptions were to be seen all over this part of the grounds. The Atco motor machine (22in.) appears to be an ideal machine for large gardens, tennis clubs, bowling greens and golf courses. The cost of running is estimated at 2d. per 1,000 square yards of grass. This firm offer to give free of charge demonstrations with the machine in any part of the country.

Messrs. Ransomes, Sims and Jefferies had several of their well known machines on show, including the motor and "push" varieties.

The Waltham Engineering Company, Limited, had some strong-looking motor machines (24in.).

The "J. P." super-lawn mower struck one as a very sound engineering proposition. The machine is easy to push, as ball bearings are fitted to both back axle drive and rotary cylinder cutter spindle. Spanners are not required, as simple hand wheel adjustments are attached. This machine is comparatively frictionless and particularly quiet in running. The machine, when a

catch is released and handles dropped, stands on end in a space of oims. by 17ins. Another point in this machine's favour is that the mechanism is dust-proof and dirt-proof, and runs in oil.

Motor machines were shown by the Nene Engineering Company, Limited.

The Multiflora Company, Limited had a collection of garden vases outside one of the large tents. These were of various designs and sizes.

A. Smellie and Co., Limited, exhibited garden netting, hoses, water-cans and garden tools.

Water-cans only were shown by Mr. J. Haws. These were of all sizes and patterns.

Beehives and all apparatus relating to bees and fruit storing appliances were shown by the well known firm of E. H. Taylor, Limited, Welwyn.

The famous Horse Shoe boiler was shown by Chas. P. Kinnell and Co., Limited, who also exhibited radiators.

The Wilkinson Sword Company showed their pruners, which are now becoming well known.

The popular *Plucca* pruner was shown by the Elliott Pruner Company.

The famous "Pattisson" horse boots were to be seen on H. Pattisson and Co.'s stand. Other important things to be seen here were "Graduator" distributor (an effective top-dresser for lawns), and a great assortment of garden tools and syringes.

Messrs. J. Weeks had a collection of heating apparatus both for small and large houses.

Wm. Cooper and Nephews, Limited, had a vast collection of weed-killers, spraying machines and spraying fluids.

The popular *Cloche* clip was exhibited by the *Cloche* Clip Company. This is an indispensable thing in the rock garden during the winter months when one wishes to protect some choice plant. Glass can easily be fixed over the plant by means of this clip. The Chase Continuous *Cloche* showed their very well known *cloche*.

A new garden plough was shown by Motes, Limited. It is called the "Titan" Horti Plow. This plough does away with digging. It is easy to use and should prove extremely useful to the gardener.

Fruit tree protectors were shown by Major C. Walker. Invaluable against the depredations of birds, wasps, frost and wind.

Messrs. Skelton and Kirby showed their patent tennis posts.

Conservatories and plant houses were exhibited by Messenger and Co., Limited, who also showed heating apparatus.

OFFICIAL LIST OF AWARDS

Sherwood Cup for the most meritorious exhibit in the Show: Messrs. R. Wallace and Co., for their exhibit in the tent.

Cain Cup for the best exhibit by an amateur: The Hon. Vicary Gibbs.

Silver-gilt Lindley Medal for cultivation: E. Beckett, V.M.H., H. Cunningham.

Model Gardens.—Gold medal: G. Bunyard and Co., Limited. Small silver cup: Herbert Jones, R. Wallace and Co. Silver-gilt Flora medal: Cheal and Sons, W. H. Gaze and Sons, Limited, John Waterer, Sons and Crisp, Limited. Silver-gilt Banksian medal: E. Dixon, "Ent-Tout-Cas," Gilliam (Croydon) and Co., R. Neal and Son, James Carter and Co.

Rock Gardens.—*Daily Graphic Cup*: Pulham and Sons. Gold medal and congratulations: R. Tucker and Sons. Large silver cup: G. G. Whitelegg and Co. Large silver cup: B. H. B. Symons-Jenne. Silver-gilt Flora medal: Hodsons, Limited, Kent and Brydon. Silver-gilt Banksian medal: Clarence Elliott, Limited.

Flowering Trees and Shrubs.—Gold medal: R. and G. Cuthbert, R. Wallace and Co., John Waterer, Sons and Crisp. Small silver cup: R. Gill and Sons. Silver-gilt Flora medal: Donard Nursery Company, William Cuthbert and Son, the Hon. B. D. McLaren, R. C. Notcutt, G. Reuther, Yokohama Nursery Company, J. Cheal and Sons, Limited. Silver-gilt Banksian medal: J. C. Allgrove, Fletcher Brothers, Hillier and Sons, Limited, T. Lewis, Stuart Low and Co. Silver Flora medal: John Waterer, Sons and Crisp, Limited.

Roses.—Large silver cup: William Paul and Son, Limited. Small silver cup: Elisha J. Hicks. Silver-gilt Flora medal: Benjamin R. Cant and Sons. Silver-gilt

Banksian medal: William Cuthbert and Son, G. Paul and Sons. Silver Flora medal: F. Cant and Co., George Prince. Silver Banksian medal: The Rev. J. H. Pemberton, Charles Turner.

Carnations.—Gold medal: Allwood Brothers. Allwood Bowl: The Right Hon. Lord Lambourne, C.V.O. Large silver cup: C. Engelmann. Silver-gilt Flora medal: William Cuthbert and Son, Stuart Low and Co., James Douglas, J. Lakeman, C. H. Herbert. Silver-gilt Banksian medal: K. Luxford and Co.

Tulips.—Gold medal: Dobbie and Co., Limited. Large silver cup: Barr and Sons. Small silver cup: Anglesey Bull Growers Association. Silver-gilt Banksian medal: R. H. Bath, Limited. Silver Flora medal: Ryder and Son, Limited.

Hardy Plants.—Large silver cup: G. Jackman and Sons. Small silver cup: Storrie and Storrie. Silver-gilt Flora medal: Amos Perry, H. J. Jones, John Waterer Sons and Crisp, J. C. Allgrove. Silver-gilt Banksian medal: J. Piper and Sons, G. and A. Clark, Limited. Silver Flora medal: B. Ladhams, Limited, W. H. Rogers and Sons, W. Wells, junr., Skelton and Kirby, E. Scaplehorn, Rich and Co. Silver Banksian medal: G. G. Whitelegg and Co., John Peed and Sons, G. R. Downer, G. W. Miller.

Rock Plants, etc.—Gold medal: M. Pritchard and Sons. Silver-gilt Lindley medal: John MacWatt. Large silver cup: Bers, Limited. Silver-gilt Flora medal: Bakers, Limited, Bowell and Skarratt, Clarence Elliott, Limited, Maxwell and Beale, G. Reuther, R. Tucker and Sons. Silver-gilt Banksian medal: Carter Page and Co., J. Cheal and Sons, Limited, R. M. Pritchard, John Waterer, Sons

and Crisp. Silver Flora medal: H. Hemsley, the Misses Hopkins.

Stove, Greenhouse and Conservatory Plants.—Gold medal: Sir George Holford, K.C.V.O. (gardener, H. G. Alexander), L. R. Russell, James Carter and Co., Sutton and Sons, Blackmore and Langdon. Small silver cup: Dobbie and Co. Silver-gilt Flora medal: Baron B. Schröder (gardener, E. J. Henderson), L. R. Russell, John Peed and Sons. Silver Flora medal: Mr. A. F. Wootton, K.C., R. Ellison. Silver Banksian medal: Webb and Son, Storrie and Storrie, Chalk Hill Nurseries. Bronze Flora medal: Jarman and Co., Godfrey and Son.

Sweet Peas.—Gold medal: Dobbie and Co. Large silver cup: Alex. Dickson and Sons, Limited. Silver-gilt Banksian medal: R. Bolton and Son, A. Ireland and Hitchcock. Silver Flora medal: J. Stevenson.

Vegetables.—Gold medal and congratulations: The Hon. Vicary Gibbs (gardener, E. Beckett).

Fruits.—Gold medal: G. Bunyard and Co. Silver-gilt Hogg medal: Rivers and Son, Limited. Bronze Hogg medal: Laxton Brothers.

Clipped Trees.—Silver Flora medal: J. Klinkert, William Cuthbert and Son, Farnow and Sons.

Hardy Grasses.—Gold medal: James MacDonoald.

Orchids.—Gold medal: Sir Jeremiah Colmao, Bart. (gardener, J. Collier), Charlesworth and Co. Small silver cup: Stuart Low and Co. Silver-gilt Flora medal: James Cypher and Son, James and A. McBean, Sanders. Silver-gilt Banksian medal: Mansell and Hatcher, Limited. Silver Banksian medal: H. Dixon, Flory and Black. Vote of thanks: Armstrong and Brown, Ch. Vulsteke.

ROYAL NATIONAL TULIP SHOW

This annual Show, which opened on the second day of "Chelsea," is now the veriest shadow of what it must have been in the thirties and forties of the nineteenth century. Those who are conversant with the *Midland Florist* and *The Gossip of the Garden*—two famous florists' periodicals of a bygone age—know what excitement the annual show once caused in floral circles. Now the interest—as evidenced in the proceedings of the present Show—is very limited. The exhibitors could easily be counted on the fingers of two hands, and at no time was there a great crush of visitors. I suppose people do not appreciate the glorious refined beauty which was to be seen in a grand flamed Sir Joseph Paxton, or in an almost equally good Trip to Stockport. Nor can they see anything of the purity of colour in such a breeder as Mr. Bentley's Glean. They prefer a Darwin like Farncombe Sanders or Isis—undoubtedly fine garden plants which the more delicate and refined florists' Tulips are not. I do not think they ever were. They never were means to an end—the end being garden embellishment. *They were the end themselves.* When Mr. Groom of Clapham Rise in the year (let us say) 1847, made his great Tulip bed of 50yds. in length and just over 4ft. wide, and put framing over the whole, covered with white linen on top and with rough canvas round the sides, he did not intend it to be an ornament to his garden. He erected it because the beauty of his Tulips demanded it. Perhaps it was more spacious than it need have been if it was only the flowers that were to be thought of. The blooming of Mr. Groom's Tulips was quite as great a society event as "Chelsea" itself. "All London" went to see them and to be seen. I am not going to argue the point whether we ought to have gardens for our flowers or flowers for our gardens. Popular opinion for the time being has decided we have flowers for our gardens; and so, although we do not "bed out" in the old fashioned way, we have colour schemes in our borders, and "drifts" in our rock work, and we humbly worship the great god Size, and we forget the rights (I can call them nothing else), of the individual flower in itself. Thus it comes about that the beautiful old rectified Tulips are passed by on the other side by so many of our modern gardeners. Perhaps the time will come when they will become fashionable again. All good things are not always appreciated as they should be. Every time I visit London I am filled with amazement at the way my fellow human beings treat the "moving stairs." They hurry up and down them as if they were treading

on very hot iron. Sometimes I think I see signs of the dawn of a greater common sense; and then it is as bad as ever and the crowd go up and down with more and more determination. It is so with the appreciation of the florists' Tulip. One year there seems to be that little cloud of greater interest on the horizon—only a man's hand in size, but full of possibilities; but the year after it has gone. One of these lean years is 1922. But for Mr. J. W. Bentley from Lancashire and Mr. Peters from Cambridge it would have been a sorry sight. The first named simply swept the board. "Every shy a coconut." Every exhibit of J. W. B. a first prize. He won the twelve Dissimilar Rectified Tulips, and the "size." He won the three flamed and the three feathered Tulips. He came out top in both the six and the three Breeder Tulips. Lastly the Samuel Barlow prize for the best "pair of Rectified Tulips, one feathered and one flamed" went to him and he had the premier Breeder in Glean and the premier flamed in Sir Joseph Paxton. The premier feathered was not marked when I came away. The runner-up in most cases was Mr. Peters, our Secretary, but Sir A. D. Hall and Mr. A. E. Chater cut in sometimes. Messrs. Barr and Sons had a nice display of May-flowering varieties on one side of the entrance and on the other a large flat board covered with specimen blooms of some of the best known "show" flowers. It was very useful for identification. A glance, for example, showed how Dr. Hardy differs from Sir Joseph Paxton; and the breeder Aglair from the breeder form of Trip to Stockport. For these two exhibits they were awarded a gold medal.

There are many who take an interest in old local dialects and old words and phrases. They feel the old times are indeed passing when these are fast becoming obsolete. Take plant names as an example. What names we find in Holland and Britten and in Prior! Are a tittle of them in use at the present? There is a Tulip language, not very old, of course, compared with the hoary age of the majority of names in these two dictionaries, but yet most expressive and in a way topical in the British "show" era. The best example is a "crinoline"—This is the chip or cardboard circle which is put into the blooms to enable them to carry well to a show. I must try to rescue these names. Here are three more expressive terms whose significance is only known to the elect—(1) Bald. (2) It puts its breeches on. (3) Beard. There are many others. What other flower is there that can boast such a broad-based colloquial vocabulary as the Tulip? JOSEPH JACOB.

CORRESPONDENCE

SOWING WALLFLOWERS.

IN his thoughtfully compiled calendar Mr. H. Turner (page 231) advises the immediate sowing of Wallflowers, those plants which add a beautiful and fragrant feature to all spring gardens. I know, of course, that the end of May is almost invariably recommended as the best time for this operation nowadays, but have never heard a sound reason in support of it. I have found that from the Trent southwards the end of June is plenty early enough, and that there is no cause for anxiety if the sowing is forced backwards until the third week of July. Last season, perforce of circumstances, I was unable to sow until the last week of July, and the results are most gratifyingly satisfactory. A friendly neighbouring gardener, who is a confirmed third week of May sower, told me on the occasion of a visit on May 12 that mine was the finest show he had seen this year, though, perchance, the villain flattered (we gardeners are prone, perhaps, to a little mutual, gentle back scratching)! My procedure is simple. If the ground is dry it is thoroughly moistened in the evening ready for seeding the next day; distribution is thin to the irreducible minimum in drills 6ins. asunder and about ½ in. deep; and my favourite time the first week of July. Little thinning is demanded, but it has attention promptly and the surface is kept open by frequent pricking over with a hand fork on a hoe shaft. When the youngsters are in, high they go to nursery beds firmly with a distance of roins. between the rows and 6ins. in them. Transference to flowering positions is done firmly in October, usually the second half. The points are not pinched out. My soil is a strong loam lying from 12ins. to 18ins. deep over Oxford clay, and it will grow anything—if it is humoured.—H. L. □

TULIP COMBINATIONS.

MAY I add three more combinations to my list in THE GARDEN for May 20th? (1) Tulipe Noire with Bouton d'Or. (2) Clara Butt (pink) with Imperial Blue Forget-me-not. (3) A pale yellow Tulip like Moonlight with blue Scilla campanulata.

The first two suggestions have been sent me by a friend. The last combination turned up unexpectedly in my own garden. The "sympathy" (to use a very old gardening word in both its ancient and modern sense) which exists between Scillas campanulata and nutans, and all May-flowering Tulips is impressed upon me more and more every year. There seems to be a Scilla, although their colour range is not a very wide one, to go with every Tulip. I only wish I had room to experiment on a fairly large scale.—JOSEPH JACOB.

EARLY TULIP CARDINAL RAMPOLLA.

ONE of the sights in my garden in the second week of May was a mass of the little known early Tulip Cardinal Rampolla. It was such a favourite with all my visitors! It is a singularly bright and happy-looking flower with its combination of rich yellow and pale reddish orange colouring. The Cardinal knows his Milton. He speaks—Listen!

"Hence loath'd melancholy

Of Cerberus and blackest midnight born."

If any flower can cure the doleful dumps, surely this can. Try it next year and see if this is not true. It is not very far removed from General de Wet in colour. It has the same tone, but the impression it gives to a bystander is very different. You cannot feel you are in the presence of one of the astutest diplomats of modern times. Its name

does not seem to fit it. It ought to be "Bindle!" —MÆLOR.

THE GREEN-FLOWERED HELLEBORE.

IF by "the green, winter-flowering Hellebore," Miss Case (page 242) means the tall *Helleborus fetidus*, I can, if she will give me her address, supply her with plenty of seed in a few weeks' time. Had I known her wishes before the borders were weeded, I could have sent seedlings, hundreds of which have to be rooted out every year. Last winter it began to flower on December 23.—HERBERT MAXWELL, *Monreith*.

A HIMALAYAN RHODODENDRON.

WE have been unable to name the Rhododendron of the picture, and wonder if you can help us. In an early season like 1921 it is in full bloom by the middle of March. I enclose a specimen for you to see.—(Mrs.) R. E. DEBENHAM.

[Our correspondent's plant is one of the many forms or varieties of the beautiful Himalayan

A FINE SPECIMEN OF RHODODENDRON ARBOREUM CINNAMOMEUM.

Rhododendron arboreum—the one known as var. *cinnamomeum*, in reference to the colour of the underside of the leaf. It is a distinct and desirable evergreen flowering shrub for Southern and Western gardens. In Cornish gardens specimens 20ft. or more in height are not uncommon. That this favoured county has rivals is apparent from the illustration of this beautiful Rhododendron sent by our correspondent from her garden near Chard, Somerset. This is, in fact, one of the hardiest forms of *R. arboreum*. It has white, freely spotted flowers and rather smaller leaves than most of the forms of *R. arboreum*. It was first grown in this country from seeds sent home by Wallich in 1822, the first recorded specimen to flower being in Messrs. Rolleson's greenhouses at Tooting in 1836. The plant is figured as *R. cinnamomeum* in the *Botanical Magazine*, tab. 3,290. In a sheltered part of the Rhododendron Dell at Kew a bush 5ft. to 6ft. high flowers annually in March or April. In the milder parts of the country the flowering is earlier, though this year Mrs. Debenham's bush was at least a month later in flowering.—ED.]

THE DAFFODIL SEASON OF 1922.

THIS season is certainly the "strangest" on my records for nineteen years. The records of first bloom of various sorts show an average start, with the Golden Spur, but the continuous cold winds dragged out the succession of kinds with the result that, as Mr. Pearson says, early and later sorts opened all together when a warmer spell did at last come. *Recurvus*, the last but one on my list, opened on May 16, two days later than in 1908, my previous record for lateness. But 1908 commenced (with Golden Spur) on April 4, twenty days later than this year. We are nearly one month later, for most varieties, than last year, which commenced on March 10, as against March 15 this year. Most of the earlier kinds were pinched and "unkind," but with warmer nights the later bloom has been, as Mr. Pearson notes strong and healthy.—ALFRED H. BASSANO, *Old Hill, Staffs*.

CUT FLOWERS BY POST OR RAIL.

I AM moved to write upon the above subject owing to the painful experiences I have had through the carelessness of people who send samples of flowers, sometimes to get them named, at other times to try to effect a sale. At the present moment there are in my office (1) Several blooms of trumpet Daffodils sent by a Dutch grower as samples in hopes of selling stocks. They all arrived *perfectly dead*, and one could only say "this was a yellow trumpet Daffodil, that was a pale trumpet Daffodil," etc., but as to any chance of seeing their merits or demerits, they might as well have never been sent. (2) A sort of herbarium specimen of a trumpet Daffodil, quite dry and brown, said to be a pale bicolor, but it might have been any colour. (3) Several poor specimens of far-gone Daffodils with hardly any stalks, one quite dead and beyond recognition. Now it seems a pity that folk should take the trouble to send blooms and pay postage and not take a little *more* trouble to ensure their arriving in decent condition. Let me give a few hints which, if faithfully carried out, should ensure the flowers arriving in really good order. Firstly, select if possible young blooms, preferably those only half open. Secondly, gather early in

the day and put the flowers in water for some hours before packing. Thirdly, pack in a box which will not crush. Ordinary cardboard boxes usually arrive squashed more or less out of shape. Fourthly, pack fairly tightly in some damp material, and cover up so as to exclude air as much as possible. My own practice is to line a wooden or very strong cardboard box with damp wadding—damped with a fine sprayer—pack in the flowers fairly tightly, and then cover with another sheet of damp wadding, tucking it carefully around the sides of the box; then put on lid and fasten up. Many people have a horror of wadding, and they may well have if it be used dry, but if sprayed I will back it against any other packing material. The next best thing to wadding is clean grass, and an additional safeguard is to tie some wet moss round the end of the flower-stalks. If one is sending Daffodils to one's friends, they should be made up in flat bunches, with the faces of blooms all one way. Two bunches can then be laid with stalks to middle and flowers to either end of box, bedded on damp wadding. Then

with a packing-needle thread a bit of tape or string through the bottom of the box—between the sides and bottom is the easiest plan—over flower-stalks and out at the other side of box, tying off securely on outside of the bottom of box. If string be used for tying down, put a pad of wadding between your string and flower-stalks, or the stalks will be injured. A bit of damp wadding as a coverlet and the box is ready for fastening down. If these instructions be faithfully carried out and the flowers fail to arrive at their destination in good condition it will be owing to some unforeseen mishap, not from the fault of the method employed, for I have packed

joy your friend will have in watching the blooms expand and improve for a day or two instead of seeing signs of decay which might be looked for had the blooms been old when cut.—J. DUNCAN PEARSON, *Lowdham, Notts.*

HOME-GROWN TULIPS.

I THINK your readers may be interested in the enclosed picture of May-flowering Tulips cultivated in a small Tooting garden. Mr. W. O'Sullivan, the garden owner, grows his own bulbs—3,000 of them—and, necessarily, grows them each season on the same ground. There are

TULIP FARMING IN A SUBURBAN GARDEN.

and had packed perhaps hundreds of lots of choice flowers for post and rail, and do not remember one case of an arrival of dead or bruised blooms. All this may seem a lot of trouble, but, after all, it always means time and trouble to cut and send off flowers, and surely it is better to give a little more time and get good results than to do the work hurriedly and hear of dead or moribund flowers arriving at the other end of their journey. A last word: In cutting Daffodils to post to your friends, always select the half-open buds. You will get far more into the box, and think of the

180 varieties in his collection. Mr. O'Sullivan is strongly of the opinion that British-grown bulbs are better than Dutch. His soil is of the light sandy texture suitable, with good cultivation, for these flowers. I am sorry I cannot send you a better photograph, but the hot weather, as you will doubtless be aware, has "knocked off" such flowers very rapidly. The picture will at any rate suggest what an array there has been. Although grown in such large masses, the bulbs are very skilfully arranged to prevent clashing of colour.—H. C.

GARDENING OF THE WEEK

FOR SOUTHERN GARDENS.

The Kitchen Garden.

New Zealand Spinach.—Where the soil is very light and porous this is an excellent variety to rely upon to produce a regular supply of leaves during the hot weather. Probably the best way is to sow in boxes under glass and plant out when large enough. This Spinach requires plenty of room for development and when planting allow from 2ft. to 3ft. between the rows and about 2ft. from plant to plant.

Outdoor Tomatoes. The plants may be placed into their fruiting quarters as soon as convenient, so as to get as long a season of growth as possible. Any vacant spots between fruit trees on warm walls or buildings, etc., are excellent positions for this crop and generally give much better results than planting out in the open. If the latter is the only available position, choose the warmest, and plant in rows running north and south on firm ground, not too rich. Allow a space of 18ins. from plant to plant and 3ft. between the rows.

Garden Swedes.—Where a large and regular supply of winter and early spring vegetables is required, these are an excellent help and they will stand more severe weather than Turnips. Seed may be sown any time from now until July in rows 20ins. apart.

The Flower Garden.

Annuals sown out of doors directly into their flowering quarters will repay early and free thinning, allowing each plant room for proper development. Half hardy annuals raised under glass should now be placed in their final quarters as soon as possible. Where any support is required for some varieties later, twiggy sticks will be found in the majority of cases to answer very well.

Specimen Plants in tubs or large pots grown for placing in positions about the grounds should be encouraged as much as possible to make good growth by an occasional soaking of a suitable stimulant. Great care is necessary in allotting sites for such plants for unless placed suitably in accordance with surroundings, etc., it is far wiser to keep them near an entrance to some conservatory or such-like structure.

Vases or Window Boxes are occasionally required for furnishing a balcony or terrace steps. Before filling such receptacles with fresh soil make sure that suitable drainage is supplied, placing over the same a layer of fibrous loam and some well rotted manure into which the roots may penetrate and obtain nourishment during the hot weather. The aspect should largely influence the kinds of plants to be used, but for a sunny position the ivy-leaved Pelargoniums are still some of the

best, while positions less sunny would accommodate Heliotropes and Fuchsias.

Fruits Under Glass.

Colouring Grapes.—To obtain well finished Grapes it is necessary to bear in mind a few practical points. It may be at once accepted as impossible to expect a really first class finish unless the roots are in a healthy condition. Apart from this, however, there are a few points for the beginner to give attention to. When coloration has just set in it is quite wrong at once to alter the daily routine of culture, for this will do precisely the opposite to helping to arrive at a good finish. Allow the practised routine to continue just as before and only gradually reduce atmospheric moisture, and arrive at a much freer circulation of air by the time colouring is well advanced. Keep the hot water pipes lukewarm day and night, with a little air on the house always. Under no circumstances must the roots of Vines suffer from dryness, and although such frequent applications of water are not required or advisable, when the ripening stage is well advanced as when in full growth, it will not harm in the least thoroughly to water Vines laden with ripe fruit so long as there is always a circulation of air and the hot water pipes are slightly warmed.

H. TURNER

(Gardener to the Duke of Northumberland),
Albury Park Gardens, Guildford.

FOR NORTHERN GARDENS.

The Kitchen Garden.

Earthing Up Growing Crops.—This is one of the most important points in the cultivation of kitchen garden crops. It is of special value to crops growing on stiff clayey soils where young plants have little encouragement to induce a downward tendency of the roots. Before earthing up takes place the soil should be thoroughly loosened and broken up between the rows with a digging fork.

The Brassica family responds quickly to this treatment, as the earthing process not only stimulates growth and encourages root action, but also serves to steady the young plants and prevents that swaying which readily damages the roots. Both Broad Beans and Kidney Beans enjoy this attention and will repay the trouble by a sturdy growth and more abundant yield.

Tomatoes.—Give a generous top dressing to plants that are carrying heavy crops, using good fibrous loam with a sprinkling of artificial manure added. Watering should also receive careful attention so that no dryness may occur at the roots, equal care being taken that the pots or borders do not get into a sodden state, as the Tomato quickly resents this. Keep all side growths rubbed off and tie in the leading shoot carefully.

Vegetable Marrows.—Plants for the principal crop will now be ready for transferring to the open. Plant on slightly raised hillocks composed of well rotted manure and good soil. Should the evenings prove chilly, some shelter may be afforded by placing short Spruce branches round the plants. See that the roots are moist before planting.

Cauliflowers.—Further plantings should now be made of Walcheren, Eclipse, and Autumn Giant. In gardens where the soil is cold and heavy, root action may be quickened by adding a trowelful of old potting soil to each plant.

Cucumbers.—Frame Cucumbers may now be planted and with abundance of solar heat will soon make rapid growth. Pinch the leading shoot when about 18ins. in length and thus encourage the quantity of lateral growths necessary for filling the allotted space. Syringe the plants during the afternoon and close the frame early enough to conserve a certain amount of sun heat.

The Flower Garden.

Thinning of Annuals.—This essential in the successful cultivation of annuals sown in the open must not be delayed, as early thinning allows for the proper development of the young plants. Choose a showery day for the work. Further sowings of annuals may yet be made over the site of Daffodils or Tulips that are permanencies in the border.

Border Chrysanthemums should be planted out without further loss of time, and where the young plants have been well grown by being transplanted in frames, they will lift with strong roots and quickly establish themselves in their flowering quarters. Chrysanthemums are charming when grouped in the mixed border and provide a wealth of bloom for cutting purposes.

THE PROPAGATION OF ALPINES

Few amateur gardeners sufficiently appreciate the opportunities for propagation afforded by warm soil and pushing vegetation.

JUNE is an exceptionally busy month in the hardy plant nursery, owing to the immense amount of propagation which may then be undertaken. The garden lover who propagates only for his own requirements may well follow the good example though he should not slavishly follow nursery methods. The nurserymen, for example, propagate his alpines into pots, since it is convenient for him and for his clientele to supply the young plants in pots. Certain choice small-growing species the amateur will also propagate into pots or pans, but the generality of furnishing plants for the rockery will be better propagated in a border, temporary shelter being afforded them while they are becoming established. Such plants will be much larger and more robust when wanted for transference to the rock garden than if they have been confined to a meagre quantity of soil in a flower-pot.

Given suitable mould in which to root them, the following are some of the plants which will be better without potting: all the Aubrietias, all varieties of Phlox subulata, Phlox amoena and P. ovata, Androsace carnea and related forms, Gentiana Gentianella, G. Kochiana, G. Clusii, the dwarf Achilleas, Antennarias, Herniarias, Arabises, Asters, such Campanulas as carpatica (including turbinata) and pusilla, Cerastiums, such dwarf Pinks as Dianthus caesus, D. superbus, D. sylvestris, D. deltoides and the cluster headed species—D. Carthusianorum and the rest—the Drabas (except D. pyrenaica), Erinus alpinus, the Erigerons, Ericas, Erysimums,

Geraniums, Erodiums, Geums, Globularias, the various species and forms of Edelweiss, the dwarf Gypsophilas, Hutchinsias, such Linarias as readily propagate by division, Liniums, Polygalas, practically all the Potentillas except nitida, most of the auricula-leaved forms of Primula and P. integrifolia, Saponarias, Sedums, Sempervivums, the mossy (Dactyloides) Saxifrages and most of the encrusted forms (but unless with special preparations, not the Kabschia varieties) the more robust Silenes, such as alpestris, Schafta and acaulis, Thalictrums, Vacciniums, Veronicas (herbaceous and shrubby), and the more robust Violas such as V. cornuta and V. gracilis.

It is not possible in the course of an article to describe minutely the propagation of each species, but the following hints as to the *modus operandi* for each of several distinct plants should

be helpful. As our first example let us take one of the various garden varieties of Phlox subulata. The variety is immaterial, as, although they differ materially in habit and outward appearance, their fundamental structure is similar. Let us carefully lift a two year old plant with a garden fork and carefully detach the soil from its roots. Should the soil in which it has been growing be light in texture and gritty, it may readily be broken up and removed with the fingers without materially damaging the rootlets, but if the plant has been growing in a rather sticky—though not necessarily heavy—loam, it may be necessary to soak the plant for a few minutes in a pail of water to separate roots from soil.

The roots free from soil, it is easy to see how the root-stock may be so divided up as to provide each portion of top with, at any rate, some roots.

Large pieces, equal perhaps to one quarter of the original plant, will look awkward when divided as the plant will, perhaps, be a couple of feet long, a little growth at one end and the roots at the other. Yet even such pieces will form useful plants if the spare stem and root is carefully wound round before planting so that all is buried except zins, or zins, of top.

Care must be taken in the bending or the brittle stem will fracture. Better still, where they are to be found, are the small pieces of year-old wood with a few rootlets at the base. These are quite straightforward to propagate. They merely need planting firmly in the compost. Large pieces and small pieces may all go under the same light, or if a light is not available, be subjected

READILY PROPAGATED UNDER LIGHTS, MOSSY SAXIFRAGES, ALPINE PHLOXES, ALYSSUMS, AND IBERISES.

THE BEAUTIFUL SANFRAGA LILACINA MAY BE PROPAGATED ON A "BARROW."

GENTIANA GENTIANELLA LOVES A STONY SOIL.

AN EASILY PROPAGATED ROCK PINK, DIANTHUS CÆSIUS.

to the same treatment, but if a large stock is required it will be necessary to take cuttings and as these have to form an entirely new root system the cuttings should be placed under a light by themselves. The cuttings should be made of one year old wood with a "heel" of the previous year's wood attached. These alpine Phloxes are readily rooted in any light gritty soil, not over rich in humus, but new soil from a light pasture is the best possible rooting medium. So quickly and readily do they establish themselves that for divided pieces a light is not really necessary. Scrim canvas shading or even sheets of newspaper held in position on the plants on hot sunny days by large stones will afford them the needed assistance.

The method of propagation outlined for alpine Phloxes will exactly apply to the Aubrietias, but as these latter do not love sunshine and heat as do the Phloxes, more protection will be necessary to prevent excessive transpiration and, should it be a hot summer, they will need more aftercare. The Erysimums need very similar treatment, but small rooted pieces are as a rule not easy to find and cuttings often have to be pressed into service. Such things as Hutchinsia are exceedingly easy to divide.

The Gentianella is quite easy to divide and it is astonishing to find how much larger a lifted clump is than it appears. Next year's growths are then exposed as stout "wires" and careful lifting is necessary to prevent these being broken off. The Gentianella loves stony ground and it is wise to introduce coarse gravel into the propagating bed and to press a few pieces of stone around the collars of the plants. Gentiana Kochiana also likes stones. It will grow in any lime-free soil, but the introduction of a little peat is helpful. G. Clusii must have lime and this is best afforded by using old mortar rubble in the compost.

The "Mossy" Saxifrages should be divided carefully and placed in gritty soil in a border which gets shade from the mid-day sun. They may succeed in the open garden nine years out of ten, but in a really droughty summer it is almost impossible to keep them alive in such a position. Pieces of stone placed round the little clumps as they are planted will help to retain the moisture and will also protect the crowns from splashing by heavy rain, and splashing often causes rot to set in.

The encrusted Saxifrages may readily be propagated outdoors if a stone-edged "barrow" be formed and they be planted therein sideways. If well rooted pieces are used no light will be necessary. Even the stronger-growing of the beautiful tufted (Kabschia) Saxifrages may be readily increased on such a barrow. Species which come to mind as suitable are S.S. apiculata, sancta, Pseudo-sancta and Rocheliana.

The Heaths are, in nurseries, usually increased from cuttings, but this method is painfully slow and the amateur may, with a little forethought, increase them quite rapidly by division. It is, quite apart from propagation, very desirable to plant Heaths very deeply, thus making the tops compact and neat. Their subsequent behaviour will largely depend upon the compost in which they are growing. Should this be peaty, they will grow rather loosely and will comparatively soon need dividing and re-planting, but in light gritty and, of course, lime-free soil, with no appreciable peat content, they will grow close and dwarf. In any event such deeply planted plants are easy to propagate as they will be found to root right up to the surface of the ground and so may readily be increased by division. It is not wise to cut off the lower roots when planting. The plants do much better if these are curled round in the manner recommended for the Phloxes.

There is no need whatever to rig up a range of Cucumber frames for alpine propagation. A few 6ft. by 4ft. lights, or even smaller ones if needs be, and a "box" or two made of lin. board, 7ins. wide, set on edge and nailed together to form a rough frame for the lights are all that are necessary.

Archangel mats or scrim shading applied as required are better than any form of permanent shade. In a future issue it is proposed to describe the propagation of some choicer alpine both outdoors and in pots and pans, an especially interesting pursuit.

ST. BRIGID ANEMONES

Fresh visitors to the Royal Horticultural Society's Meetings at this season always remark upon the beauty of these by no means difficult garden flowers.

THE above name has been given to a semi-double strain of the Poppy Anemone (*A. coronaria*), which was introduced from the Levant in 1596, but also grows in South Europe along the Mediterranean littoral. The species has always been more or less popular in this country, and Parkinson enumerated thirty varieties in his day, while Mason in 1820 catalogued seventy-five varieties.

colouring of the flowers are so characteristic in their way that they should become as indispensable in the garden as the Tulips, with which they do not compete. This may be the case when the younger generation of admirers has acquired the art of cultivating the plant with success.

THEIR PROPAGATION.

As in the case of the tuberous Begonia, the tubers may be divided and every piece will grow,

The soil for rearing these Anemones should have a heavy dressing of leaf-soil or half-decayed leaves and road grit or coarse sand. Dig this deeply or even twice thoroughly to incorporate the different materials, level the bed and rake it smooth. Draw furrows less than half an inch deep, so that the seeds will only be lightly covered, and the lines 10ins. to 12ins. apart if the bed has to be kept clean by hoeing. Six inches apart will be sufficient if hand weeding is practised. Give water at frequent intervals during droughty periods. A top-dressing of rich soil will greatly benefit the seedlings as they begin to grow. Many of them will bloom during the following April if given a fair amount of attention to keep them growing during the warmer part of late summer.

SOIL AND PLANTING.

The soil for these Anemones should be friable, and contain some gritty matter in it. The soil from whence the flowers have been brought to this country from Ireland is light and sandy, perhaps too sandy for open situations in droughty seasons like the last, but Ireland has usually a greater rainfall than we get in Britain, except towards the western seaboard. They are now being tried by the Irish growers on the heavier soil of West Middlesex. The soil should be dug 15ins. to 18ins. deep to get the best results, and it should be well drained, if not naturally so. Half-decayed leaves or leaf-soil should be used instead of animal manures, and this should be well incorporated with the soil while digging, not put in layers. Old turf is also excellent material to mix with the soil.

Skilled cultivators with a suitable soil can plant the tubers in almost every month of the year to get a succession, but experience has proved that the middle of October and the end of January are the two best times for planting in England. The middle of February would be more suitable for the north of Scotland. In favourable winters the finest flowers are obtained from the autumn planting. Some protection is needed for this planting if the flowers appear before sharp frosts have ceased. The tubers are best planted in beds at 6ins. to 7ins. apart and 2ins. deep. They can be planted with the trowel. Some cultivators put some silver sand below and above the tubers, especially in the North. The surface should be raked level and smooth before commencing to plant. The hole should be sufficiently wide for the tuber to be laid flat, and not much pressure should be used on the soil when covering them, otherwise some of the crowns or growing points are liable to be crushed, as they are rather brittle. Be careful to keep the right side upwards, and this can usually be recognised by the knobs on the top. A few fibres, the remains of the roots, may usually be detected on the underside.

AFTER-TREATMENT.

It is a good plan to cover the beds with 2ins. of half-decayed leaves for protection; but it may be necessary to liberate some of the foliage and flowers if they have a difficulty in piercing undecayed flakes of leaves in spring. This mulching will prove highly beneficial to the plants during spells of drought in April or May. Some cultivators mix well decayed stable manure with the leaf-soil in spring, and this top-dressing serves to nourish the plants as well as to preserve soil moisture. Autumn-planted tubers will bloom in May and spring-planted ones in June. It is good practice to lift, dry and store the tubers immediately after the foliage has completely died away and before any second growth has commenced. Where the soil is of a light character it may be possible to cultivate St. Brigid Anemones by leaving them in the soil for some years till the ground requires renovating or the tubers require to be replaced.

HORTICULTURIST.

ST. BRIGID ANEMONES.

Single, semi-double and double varieties were produced by British and Dutch cultivators early in last century.

St. Brigid Anemones are an Irish strain that has for many years past been developed to great perfection, both as regards size and colour. In the height of their season the blooms will measure 3ins. to 4ins. across. The colour ranges from white to rose, mauve, purple, crimson, scarlet and deep blue, with intermediate shades. Some are distinctly zoned with white, rose or red, others are parti-coloured. These have all been obtained by seed sowing and the selection of the brightest colours or those combinations of colours that most appeal to the sense of taste. The development of this strain has given a great impetus to the cultivation of this old garden flower, and its great beauty in the garden as well as its suitability for cutting and arranging in vases of water indoors marks it down as a plant of general utility. The dwarf habit of the plant, form and brilliant

provided it has a knob or growing point with one or more buds upon it. As a rule, large tubers should only be cut in half for bedding purposes, and smaller pieces cut off only for the increase of some special variety. Small pieces require to be grown for a year or two to get them to useful flowering size.

For general garden decoration a better way for getting a quantity is to rear them from seeds. The best time to sow seeds is as soon as they are ripe, say, some time in July. The seeds are enveloped in a woolly covering that makes them adhere in masses, so that regular and thin sowing is a matter of some difficulty. This can be surmounted by putting the seeds in a bowl, mixing them with sharp sand and rubbing the two with the fingers till they get mingled in equal proportions. Thin sowing will prevent the necessity for disturbing the seedlings till after they have flowered. The seedlings will germinate in a month or less, and keep growing till November.

GORGEOUS HIPPEASTRUMS

I AM watching just now with especial interest the rapid growth and development of the buds of the Hippeastrums (Amaryllises, many gardeners still call them). This is a batch of seedlings now pushing up buds for the first time, full of promise and pregnant with possibilities. The air seems charged with expectancy as, day by day, the stems elongate and the great buds grow fatter and fatter. What will they be? Who can say? In this case the seeds have not—so far as is known—been "crossed" with others; they were merely "mixed," handed on by a friend, but the future holds possibilities, and I feel that I must "have a finger in the pie" and a "say" in some of the inter-marriages that shall take place in that greenhouse.

These plants are among the most handsome and gorgeously coloured that can be grown in a greenhouse which is only moderately heated, and the ease with which they can be grown is each year making them more and more popular.

The name "Hippeastrum" is derived from *hippeas* (a knight) and *astron* (a star), and the present race of plants is the result of numerous crosses carried out among the natural species. To ensure success in their culture, good and suitable soil is the starting point upon which all else is founded. The large bulbs appreciate a heavy rather than a light loam, to which a moderate amount of sand, bone meal and well decayed cow manure has been added. This should be prepared some time in advance of use and should be turned several times at intervals, so that it is thoroughly mixed. Such soil will suit them to perfection, being strong and lasting, and there can be no doubt that the less the roots are disturbed, beyond actual necessity, the better. While some prefer to give the plants a season of rest, this is by no means necessary; the natural habit is evergreen, and I much prefer to keep them growing throughout the year.

Potting or repotting should be done in spring, just when new growth begins to appear, for that one may take it is synonymous with renewed root activity, and so is the most favourable time. The bulbs should have all the old soil carefully removed from the roots. This affords, too, a good opportunity to remove all easily detached offsets for purposes of propagation. The size of the pot employed differs with varieties, some making much larger bulbs than others, a 5 in. or 6 in. pot being sufficient for a 3 in. bulb, the 8 in. to 10 in. for a larger one with offsets that are not to be removed.

It is a great mistake to overpot, a good average being about twice the diameter of the bulb or clump of bulbs. Drain all pots very efficiently; stagnant water round the roots soon causes sickly foliage and, if allowed to remain, rots the bulbs. Make the soil quite firm, and plant the bulbs so that one half is below the soil and the remainder exposed. After potting, it is a good plan to sink the pots to the rim in a bed of leaf-mould or coconut fibre with a steady bottom heat, although this is not essential: they will start, although more slowly, if stood on the staging where the temperature is between 55° and 75°. The plants love plenty of light, need but little shading and appreciate free syringing with tepid

SOME HYBRID HIPPEASTRUMS.

water. As foliage growth increases, larger supplies of water should be provided at the roots. Newly-potted bulbs do not require feeding the first season, but in subsequent years liquid manure may be generously supplied as soon as the flower buds appear, continuing this, varied by plain water, until leaf growth is completed. It is really astonishing how long the plants can be kept growing in the same pots and soil by thus feeding regularly all through the growing season.

A fine group of plants that is well managed in the matter of soil, feeding, temperature, etc., presents a splendid sight indeed when the great buds expand into enormous flowers, 8 ins. to 10 in. across, varying in colour from the deepest blood crimson and scarlet to pure white, each broad-petalled flower usually showing a lighter band down the centre tinted with green.

These flowers are of equal interest with those of the tuberous *Begonia*, the *Hollyhock* and many another garden aristocrat, in that they have been produced almost solely by the patience and skill of man in hybridising numerous wild species. The history of the *Hippeastrum*, indeed, starts with a very humble beginning, for it was a Lancashire watchmaker, of the name of Johnson, who in 1799 raised the first hybrid, a cross between *H. vittatum* and *H. reginae*, and this he named after himself, *H. Johnsonii*. M. de Graff, of Leiden, took the plants in hand in 1830 and began crossing on a large scale, using such varieties as *H.H. Johnsonii*, *crocatum*, *fulgidum* and *vittatum*. In 1861 fresh blood was brought into the strain by using *H. pardinum* and, a few years later, *H. Leopoldi*. From then onwards development went forward apace, the larger flowers, greater vigour and freedom of flowering that characterise the plants owing much to the two last named Peruvian species.

The plants are not only very easy to raise from seed, but cross with equal facility, thus giving special opportunity to those who wish to experiment. Seeds should in all cases be sown immediately after they are ripe, covering very lightly with finely sifted earth. Constant watering is not desirable, and to obviate this the pans containing the seeds should be covered by a pane of glass until the young plants spear their way through the soil. The temperature should not fall below 60°, and in about a week the young plants will be through the soil. Keep the atmosphere humid, as this encourages quick growth, and as soon as large enough transfer to single pots, repeating this potting as often as necessary to ensure steady and continuous progress.

If you are intending to cross varieties the anthers should be removed from the tips of the stamens—when in the floury state—and dusted on to the three pointed stigma of another flower that is in a suitable condition. The receptivity of the stigma and the ripening of the pollen are not synonymous in the *Hippeastrum*, the pollen being mature about three days before the stigma is ready for fertilisation. Another point that is worth considering when making crosses is the breadth of the petal from which the pollen is procured. The back petal is always the widest, the two side ones slightly narrower, while the lower one is the narrowest. It has been suggested—and probably with good reason—that pollen taken from the anther which springs from the widest petal carries the factor for increased width; the trial, at any rate, is worth while. Every possible care should be taken in selecting both the seed parent and the pollen, and it is a wise precaution to repeat the cross two or three days after the initial attempt.

The *Hippeastrum* is not much infested by insect pests, although, under careless culture, aphides, red spider, mealy bug and scale will all attack them; these visitations are largely the reward of neglect, light fumigation from time to time being sufficient to ensure freedom. The *Eucharis* mite is another question, however, and this little wretch will sometimes attack the bulbs. Should this occur, and if the damage has not gone too far when discovered, the damaged roots and scales may be stripped from the bulbs, which should then be thoroughly washed in a solution of liver of sulphur. They should be replanted in fresh soil and stood in a place by themselves so that they may be kept under close observation for a time.

Although I have spoken of my seedling plants as on the point of flowering, it should not be overlooked that the flowering season is quite an elastic one and can be controlled so as to give a very

prolonged season by placing some plants in a genial temperature, so encouraging early flowering and growth, while others are kept cooler and brought in, in a succession, to the higher temperature so as to provide a long succession of flowers.
H. W. CANNING-WRIGHT.

COLOUR EFFECTS IN THE FLOWER GARDEN

BY GERTRUDE JEKYL, V.M.H.

IT has been suggested that occasional notes throughout the summer under this heading may be of use and encouragement to some who may wish to use colour pictorially. Those who have once attempted this, and who have met with some measure of success, will always be trying for something more in the way of beautiful combinations and sequences. The word "colour" as applied to gardening, to many means only bright or even garish colour, something that attracts or attacks the eye by its own intensity. To the garden artist it means the employment of intentionally related or, in some cases, contrasted colouring, with the result that, while at certain points or in certain regions the most intense colour may be displayed, it has a quality of splendid richness that is the very opposite to garish vulgarity. These notes will make mention, as they occur, of some combinations that have proved successful, in the hope that they may suggest to others the study and practice of one of the most delightful and repaying of horticultural experiences.

A small section of the garden that is devoted to spring flowers has them arranged thus: On entering, there is a grouping of white and pale yellow with a gently contrasting ground of pale blue. The flowers are the Poetaz hybrid Narcissus Elvira with palest yellow bunch Primroses, and Tulips White Swan and Moonlight (faint yellow), followed by Tulipa retroflexa. The groundwork of Primroses runs into one of the pale blue Myosotis dissitiflora towards the front, and the two grounds mingle, not mixed up, but joining like the interweaving of two streams of ravelled thread. A patch of Alyssum is the strongest yellow here. The Forget-me-not trickles into a front drift of pale Aubrietia to meet patches of double Arabis. The Aubrietia darkens in colour and joins a further front planting of a rich purple Viola gracilis, backed by some little bushes of the purple leaved Sage, one of the most useful of the background plants of the spring garden.

A word about Aubrietia. I am of opinion that the truest colour of this useful spring plant is of a medium light tint. The fine dark Dr. Mules is a splendid thing, but, like many good things, it is best used with some restraint. A bold drift of Aubrietias of, say, fifteen plants of what I hold to be the type colour, with four or five plants of Dr. Mules worked in towards the back, has a much more telling effect than if the whole was of the deeper colour. The fine kind called Lavender is a good example of sweet and tender colouring with a rather large flower; but a packet of seed of true Aubrietia græca, a little deeper than Lavender, but still within, will give what I hold to be a good type colour of the plant. I am shy of the reddish varieties; at best they are a poor or heavy kind of red, but some pale pinks, such as Barr's Bridesmaid and Moerheini, are pretty and useful.

The continuation of the spring flower border has Tulips, purple and white, with a backing of purple Wallflower and the dark Honesty. The purple Wallflowers intermingle with the same in rich brown, which again pass into those of a

deep flaming orange, Sutton's Fire King and Orange Bedder. These are interplanted with tall Tulips, deep yellow, orange, brown and scarlet, in a further range of dark brown Wall-

flower. The whole of this is backed by some compact bushes of deep yellow and orange Azalea mollis, with a further backing of Berberis Darwinii and small Japanese Maples of a rich red-brown.

THE TREATMENT OF CHRYSANTHEMUMS

Plants in pots and also those in borders will require constant attention if they are in due course to yield a rich harvest of blossom. The final potting or planting out does not mean that all the important work is done.

WELL remember the time when such varieties as Mme. C. Audiguier and Belle Paule were grown and thought much of. I grew them myself for the production of exhibition blooms about thirty years ago;

the first named attained to a height of 15ft., and the latter to 13ft. Being grown on the south side of a garden wall, I used to stand on it when tying in the shoots and "taking" the buds in August. There were many varieties grown at that time that attained to a height of 7ft. to 10ft.; such tall growers would not find much favour in these days of comparatively dwarf sorts. In the days above referred to one long stake was placed in the soil in the pot and two side stakes made secure to two strands of wire, and the plants were often much broken in the autumn-time by strong winds. Amateur cultivators at the present time may make their tallest-growing varieties quite secure by using one wire made fast to posts so as to be about 3ft. 6ins. above the rims of the pots. Three stakes may be used, from 4ft. to 6ft. in length, and driven into the soil in each pot in the case of plants grown for bearing exhibition blooms, so that the specimens are held upright and firmly when the time comes for placing the plants under glass. Before the month of June is past all the necessary stakes should be fixed in the pots not only with a view to affording support in good time, but also to avoid destruction of the roots when, later on, the new soil becomes thoroughly permeated with them.

Watering is a very important part of the general management of these plants. If the new soil is kept in a constant state of excessive moisture—always sodden—new roots will not enter it, the foliage will turn yellow and many lower leaves will fall off. Neglect to apply water when it is needed will also have a bad effect, causing loss of leaves, stunting of growth and premature bud-formation. If the pot gives out a clear ring when tapped with knuckles or stick the soil is dry, and sufficient water must be applied to permeate the whole of the soil through to the drainage. Just before real dryness again occurs,

water as suggested above. In rainy weather it may be that the surface soil will be moist, while the great bulk of it is actually dry. Pay close attention to the plants' appearance and also the "ring" of the pots,

AN EXCELLENT DECORATIVE CHRYSANTHEMUM, YELLOW CAP.

and water even while it is raining if the ball prove dry.

Do not apply liquid manure before the roots are numerous in the new compost. When the pots are fairly full of roots begin with weak doses of clear soot water, and vary the feeding as much as possible. The object should be to keep the plants moving forward, gaining strength week by week, so that they will be really robust when the buds are being secured during August and the early part of September.

Specimen plants bearing from nine to twenty moderately-sized blooms are really very attractive in a greenhouse or conservatory. Having made a selection of the main shoots, the necessary stakes should be placed at once. The stakes should point outwards at an angle of about 60° the form that the plant will eventually assume. It is a rather difficult matter to stake or support such large specimens against strong winds, and I find it a good plan to sink the pots in the ground to about half their depth, putting a handful of cinders or broken clinkers under each pot to afford sound drainage. It will be advisable to stop the plants a second time to secure the number of stems and blooms, but the last stopping should not be at a later date than the last week in June.

Border plants are becoming more popular every year, and they now form an important feature in most gardens. Many of the varieties used for this purpose are dwarf growing and so do not require much staking. Those which do should

be so staked that their habit of growth is not altered and the stakes not noticeable at the time when the plants are in full flower. Soot water and liquid manure should be applied in due course to help the plants to bear fine flowers. G. G.

A COOL-GREENHOUSE BULB

The genus *Babiana* gets its name from a Dutch word meaning baboon, because these animals are very fond of the bulbous roots. It would not have mattered very much from the garden point of view if they had made a meal of all the strictas provided rubro-cyanea was left. It is out and out the most taking of them. Nothing can well be more striking, and I may add more

picture—not a particularly good one—was published in the *Botanical Magazine*. It is still scarce and seldom seen. This need not be, for there is no difficulty in connexion with its cultivation.

With us it lives with the Freesias, the only difference in the yearly cycle between them being that the *Babiana* is not potted until September,

the season with the scythe or even, where considerable areas are involved, with the mowing machine, or, perhaps better still, along the skirts of woodland, where there will be little growth of grass to cause trouble.

Once placed in the reserve garden, the bulbs must not be forgotten. Immediately the foliage is quite dead they should be lifted for storage, cleaned, sorted and dried in a moderately cool place and put away, carefully labelled, until planting-time comes round. Narcissi, in particular, have the shortest of resting periods and if left even a week or two when thoroughly ripe will almost certainly be found to have made new roots. Most growers consider it a mistake to plant Tulips too early, but this in no way applies to Narcissi, and if it is proposed to naturalise them and the ground is ready, there is no reason why they should be dried at all. They may quite well be consigned again to Mother Earth straightway.

If in "permauent" positions—that is, sites where they may each year ripen off without being an eyesore—Narcissi may remain undisturbed for a number of years, until, in fact, they show obvious signs of becoming overcrowded. The same applies to the Snakesheads and other *Fritillarias* naturalised in woodland or shrubbery, the various *Scillas* (including Bluebells), Snowdrops and the Glory of the Snow. The Crocus, however, needs replanting every two or three years, owing to its habit of lifting itself out of the ground. The Crocus, like the Tulip or Gladiolus, and unlike the Narcissus, forms a new bulb each season, the old one withering away. The new bulb is built, as it were, on top of the old one; hence the tendency of the Crocus to come above ground.

Soft-skinned bulbs, such as Lilies, *Fritillarias* and *Erythroniums*, should not be kept out of the ground longer than is absolutely necessary. The longer they can be left undisturbed, so that they do not become overcrowded, the better. It is very difficult so to time the lifting of the Crown Imperial, *Fritillaria imperialis* or the Madonna Lily, *Lilium candidum*, so that the bulbs are free from roots. Both should be lifted, if lifted they must be, just before the old foliage seems entirely dead, and the sooner the bulbs are replanted the more quickly will they overget the disturbance.

The florists' Hyacinths, forms of *Hyacinthus orientalis*, are generally supposed not to succeed permanently in Britain, but if lifted carefully from the beds and replanted in light but moderately rich soil, many bulbs will flower and increase year by year until they have formed considerable clumps. The flower spikes they will produce will not, it is true, be first size, but they will be very effective none the less, both as growing and for cut flower.

The storage of bulbs, like that of Apples, seems to present great difficulty to some people. It is a mistake to overdo drying in the sun; indeed, it is better to manage even the first rough-drying in an airy shed if possible. Direct sunshine is no good to Tulips and Daffodils; it is extremely detrimental to softer bulbs.

Once the bulbs are dry and stripped, an equable but rather cool temperature in an atmosphere just too dry to encourage growth is best. Too dry an air will cause the bulbs to shrivel. It is, in any case, not difficult to keep the bulbs dry enough in summer-time, and the wise gardener puts his bulbs (with the possible exception of Tulips) "to bed" early.

It may not be out of place to point out that hot summer days afford a fine opportunity to fallow and clean ground intended for bulbs this autumn. Such weeds as Couch Grass and Ground Elder, in particular, should have war waged upon them.

A PAN OF THE BEAUTIFUL *BABIANA STRICTA RUBRO-CYANEA*.

beautiful, than a well grown pan such as that illustrated. Each bloom consists of a central circle of a pretty shade of bright crimson with a surround of a lovely soft shade of blue. Like *Lilias*, they only expand in sunlight, but no one should be put off growing them on account of this. It only makes us value those precious hours all the more. As long ago as 1768 its

whereas the Freesias are started in August. Probably this need not be, and it would be quite right to start both at the earlier date. The little stock of rubro-cyanea grows larger each year, and I have a small pot of home-raised seedlings coming on which is undesigned evidence in favour of the treatment they receive being correct. JOSEPH JACOB.

THE CARE OF BULBS AFTER FLOWERING

MANY good bulbs every year are spoiled after flowering through carelessness or want of knowledge. If bulbs are to be left in borders for another year the foliage should on no account be removed until it has withered. Where summer bedding has to follow on, the bulbs must, of course, be lifted, which, however carefully undertaken, is detrimental to them; yet if the work be carefully performed, and especial care be taken to break the roots as little as possible, no great harm should ensue to such things as Crocuses, *Scillas*, Tulips or Narcissi if they be replanted quickly in the reserve ground, well watered in and afforded protection from hot sunshine. A

wall or fence is, of course, a ready-made and very efficient protector.

The necessity for a proper ripening-off of the foliage is the fatal drawback to the planting of bulbs in mown sward. All goes well until flowering is over, and then either the bulbs must be sacrificed or the appearance and, perhaps more important, the permanent well being of the green. Crocuses, for example, ripen off considerably earlier than Daffodils, but, even in their case, it is easy to see, the season through, by the patches of coarse verdure where the bulbs displayed their springtime beauty.

Bulbs, then, should be naturalised either in rough herbage, which may be cut, say, twice in

THE INVALUABLE PÆONY

EVERY gardener ever I met liked Pæonies, but tastes differ, and this is the season for the pencil and notebook to note down coveted sorts in one's neighbour's garden. Some there be whose fancy runs to the old double-flowered forms of *Pæonia officinalis*—*rubra plena*, *rosea plena* and *alba plena*, a grand, if changeable, trio! for all three change the colour of their expanded flowers.

To others none but the single forms make appeal, and certainly these are among the most chaste and beautiful of flowers. There are at least three single forms comparable to the old double favourites above described. These are *P. officinalis* vars.

blanda, *lobata* and *rosea*. Then there are beautiful species such as the red-flowered *tenifolia* or *Pæonia lutea*, as well as a wide range of colour in single-flowered forms of the Chinese Pæony, *Pæonia sinensis*. It may suffice to mention *Nymphe*, a lovely creamy white sort; *Victoria*, brilliant crimson, golden anthers; and *albiflora grandiflora*, with lovely white and gold saucers.

Of the double Chinese forms it is difficult to make a selection, but those who like a large, bold flower will be attracted by such as *Festiva maxima*, with large pure white blossoms, each relieved by a few rose petals, the fragrant pure white *Duchesse de Nemours*; *La Fraicheur*, with a mat

of sulphur petals surrounded by a ring of blush-pink guard petals; the somewhat similarly coloured *Thorbeckii*; the rich amaranth *Gloire de Douai*, or the purple and very sweet scented *François Ortegat*.

The Pæonies take a little time thoroughly to re-establish themselves after removal, so should be planted where they are intended to remain and spaced a fair distance apart. They have brittle, fleshy roots, so that, though they will survive if moved at any time when dormant, they are best transplanted fairly early in autumn before the foliage is quite decayed. The roots are then sufficiently active to heal up and prevent root-rot setting in. Pæonies, like the Bearded Irises, have a foliage so beautiful in itself as to render the flower but a part of their attraction. The spring, bronzy stems and foliage are an admirable foil for Daffodils and other bulbs. The leaves expand, disclosing the characteristic and interesting-looking buds which in turn give place to the weighty balls of the double sorts or the jewelled chalice of the single ones. The flowers sometimes pass, if left, to interesting seed-vessels, but the cultivator usually removes these to maintain the strength of the plant. The foliage is beautiful all summer and may be used discreetly to veil the uninteresting lower parts of certain otherwise valuable plants, such as the Anemuses, Hollyhocks, Dahlias and even Delphiniums. With early autumn the leaves take on delightful tints of russet and crimson, so that the Pæony may justly claim to be interesting and beautiful from the time when first its leaf stalks commence uncurling to the day when, its year's cycle completed, it slumbers to await another spring.

The herbaceous Pæonies, for the Tree Pæonies need special care and different treatment, are hardy enough and may safely be planted in any part of the country, but if protection from the east can be provided so much the better, for a rimy spring frost caught by the early morning sun's rays will sometimes scorch and disfigure the unfolding foliage.

A TYPICAL SINGLE PÆONY—PÆONIA ALBIFLORA THE BRIDE.

ONE OF THE FINE OLD DOUBLE PÆONIES—P. OFFICINALIS ROSEA PLENA.

WHY NOT INSTAL GLASS?

The amateur's present opportunity

FEW gardeners nowadays need instructing as to the value of glass, whether it be in the shape of greenhouses or in the humbler forms of pits and frames, in the well cultivated and efficiently kept garden. There is a universal consensus of opinion upon its general value, indeed one might almost say upon its indispensability. But it is doubtful whether the many and varied uses to which the possession of glass facilities may be put is understood by most gardeners or whether all of us realise that glass is a practical proposition within the reach of practically the humblest purse and the smallest garden.

In the not far distant past, few amateur gardeners could afford either to build houses or repair them, or even to instal panes, owing to the high cost of all the requisites. Fuel, timber, heating-apparatus, and glass itself rose in price like all other commodities, and there was not (at any rate immediately after the war) an unlimited supply to meet the demand. Recently all this has changed. The costs have fallen by percentages which are staggering. Thus British glass the best for horticultural purposes is 40 per cent. cheaper; fuel, both slack and coke, only about half its former price, and wood is easily 45 per cent. lower. Even heating apparatus

is about a third of what it was formerly so that it is impossible to name any horticultural building requisite (including labour), which is not at a temptingly low rate just now. Moreover, it is unlikely that these requisites will become lower; according to expert opinion they have reached their minimum, and it is quite possible that prices may recover somewhat in the near future. Therefore, the amateur gardener will act wisely in taking immediate advantage of the present situation so favourable to himself, especially as it may not last. The great glasshouse growers, the big professional nurserymen and the like have hardly yet recommenced making good the wartime dilapidations or entering upon fresh building plans; when they do, the increased demand may possibly be reflected in an enhanced price of all materials. Therefore, the private individual should buy and build now—while prices remain favourable and while full quantities are available, thus obviating delay.

In a May like the one we have just experienced, with frosts occurring in the mornings and a 20° fall in temperature in a day or two, the value of the protection afforded by glass is obvious. Even the humblest frame or pit with glass sashes (or "lights" as they are generally called), must have been of untold usefulness to its possessor during this abnormal spring in preserving seeds, bulbs, and young plants from Jack Frost. Then again, they have their summer as well as winter uses, for they afford a convenient means of sheltering delicate plants from scorching suns or heavy rains or hail. Apart from their purely protective purpose the exceedingly great utility of pits is worth special notice even by those gardeners who can afford more elaborate forms of glass structure. For example, pits should be employed for bringing a good stock of plants forward so that when the large houses are built they may present a gay appearance immediately and not remain for some time imperfectly furnished. The presence of pits, too, enables this procedure to be subsequently maintained from the supply which pits in good working order can afford.

With heat at command, too, pits are useful for propagation purposes and for forcing vegetables, flowers and fruit, as well as for nursing plants intended for the larger structures, in the way explained above. They are so easy to construct that an intelligent schoolboy can make them, being essentially no more than a wall-enclosed space with the glass "lights" on top. The cost need be only a few shillings, for it is by no means essential that the walls should be of brick or stone, and boxes of earth or army sand bags or turf sods can be utilised. Their size is a matter for the idiosyncrasy of the individual, but useful proportions are a 2 ft. back wall sloping to half that size in front, with about 4 ft. from front to back.

The ordinary wooden frame with a glass top is so familiar as to call for no detailed description, and excellent specimens admirably adapted for various purposes may be got from the numerous firms engaged in horticultural building work. One advantage of the frame to the small gardener is that it need not be a fixture and can be moved if necessary. The wall-frame—a more elaborate type than what may be termed the box-frame—is useful for protecting wall fruits, such as Peaches and Nectarines against late spring frosts and assisting in ripening them. It consists of covering walls with glass so that they form, in fact, a narrow house, and it partakes more or less of the character of a lean-to greenhouse. A lean-to greenhouse need be little more costly, however, than the wall frame, and it is generally worth while for the gardener to go to a little more expense, because the area enclosed is greater and he can have a command of heat. The lean-to form of house is very generally

adopted in cases where a small house is required and, of course, it enables one to take advantage of a wall already built. Plants grow there very well, but not quite so symmetrically as in span-roofed or other structures that admit light on all sides of the plants.

During recent years the importance of light for vegetation has become better known than formerly, and great improvements in the construction of greenhouses and conservatories have followed. The old-fashioned dark roof, not made of glass, is an abomination of the past. Nowadays the indispensability of glass in the roof, back and ends, as well as the front is generally recognised, for to admit light should be the aim as much as possible, and if this be kept in view and with the means of admitting air, any form of glass-house may be adopted according to circumstances. And, as already pointed out, the present is, so far as the amateur gardener is concerned, an exceptionally favourable time for the installation of glass in any form.

THE CROWEAS

These readily propagated and easily grown hard-wooded plants are not sufficiently appreciated.

THE Croweas form a small genus of pretty flowering shrubs, natives of Australia. At one time it was considered that there were several distinct species, but they have now been reduced to two, namely, the graceful-habited *Crowea angustifolia*, and the larger and more sturdy-growing *C. saligna*, often met with under the specific name of *latifolia*. This last, which will often flower during the winter months, forms a freely branched specimen clothed with evergreen, willow-like leaves. The flowers, which are of a clear deep pink colour, are very freely borne. The leaves of *C. angustifolia* are exceedingly narrow, while the starry flowers, which are produced from the axils of the leaves, are of a delightful shade of pink. The blossoms of *C. saligna* are much less star-like in shape than those of *C. angustifolia*. This last was given an award of merit by the Royal Horticultural Society on March 28, 1905.

The charm of novelty cannot be claimed for either, as *C. saligna* was introduced from New South Wales in 1791; and while I cannot find the date of the introduction of the other, it was certainly grown by our forefathers.

The Croweas, which belong to the Order Rutaceæ, need the same treatment as the general run of hard-wooded plants; that is to say, they must be potted firmly in a compost mainly consisting of peat, with the addition of a little loam and silver sand. Like Heaths and similar plants the pots prepared for their reception must be clean and effectually drained, while it is very essential that the old ball of earth be not buried deeper than it was before. A light, buoyant atmosphere just meets their requirements, and a minimum night winter temperature of 45°, rising during the day, will suit them well. The temperature named applies only to cold weather, as at all times an excess of fire-heat should be avoided. Watering, too, must be carefully done. Cuttings of the half-ripened shoots will strike in a compost made up of peat and sand pressed very firmly and covered with a bell-glass. By some cultivators they are grafted on to one of the Eriostemonas, as in this way they are considered to make stronger growth. The young plants need to have the tops pinched out once or twice during their earlier stages in order to induce a bushy habit.

H. P.

THE VALUE OF MULCHING

The best mulches and the proper method of applying them.

VERY few amateurs realise the great value of mulches to both flowers and vegetables. They say that mulches look so untidy and are greatly out of place in a small garden and they do not realise that the great fact which accrues from using mulches is that they lessen the need for watering. Now every amateur who is not lucky enough to possess a hose pipe well knows that the watering of even a small garden thoroughly is by no means a light task, and considering that mulches really lessen that often Herculean task it requires a good excuse not to use them.

The best of all mulches is, of course, well rotted stable dung, but there are other materials, such as lawn mowings, rotted vegetable manure, cowdung, road scrapings, which are favourites with some people. My opinion is that road scrapings from tarred roads should on no account be used for mulching unless they are collected in wet weather. This is not because of the supposed harmfulness of the tar (which is much exaggerated), but because the dry scrapings cake so readily on the surface soil and the water runs off the top and does not soak in.

Nearly everything is benefited by a good mulch, but such plants as Anchasus, Pyrethrums and Delphiniums are among the plants which are specially grateful, and, of course, Roses, Sweet Peas, climbing plants and many others might be named. In the vegetable garden we have Peas, French, Dwarf and Runner Beans which are most grateful for mulches of lawn clippings, and many other crops are greatly benefited by the application of mulches in very dry weather.

THE APPLICATION OF MULCHES.

It is not the least good to my mind to apply dry mulch to dry soil, nor yet wet mulch to dry soil, for then if the rain should come it has to pass through the mulch before it can reach the soil and soak in and benefit the roots as it is wanted to. If mulches are to be applied at all they should be applied well wet themselves to wet soils and to soils that have been well cultivated with the hoe prior to the rain. A good time to apply is immediately after one of those heavy thunderstorms we so often get in July. It is then that the greatest advantage accrues from the use of mulches as the rapid evaporation is greatly checked by the manure, for manure holds moisture for far longer than soil.

If, however, the Clerk of the Weather is not good enough to send a thunderstorm as soon as you have read this article do not wait for him to do so, as he may be very busy carrying out some important Scotch contracts for lightning and rain. Get out your cans and buckets and make a gallant effort to soak your plants with water and then apply the wet mulch on the top of the wet soil. Then if the Clerk of the Weather returns suddenly from Scotland and brings a thunderstorm with him a few nights later the rain will at any rate soak in and benefit the roots, whereas if both the soil and mulch were baked and dry the rain would—most of it—have run off. Some reader who has leisure and a keenness for experiment should take a definite number of plants, such as Chrysanthemums; he should apply a mulch to half the number and no mulch to the other half. If he compares these plants in a hot season he will not be slow to see the advantages of mulching, but of course, in a wet summer no real comparison could be made.

E. T. ELLIS.

CORRESPONDENCE

HAILSTORM RELIEF FUND.

MY attention has been called to the serious damage caused by the hailstorm which occurred in this borough of Tunbridge Wells on May 25 (the most terrific storm which has happened in the district for the past thirty years), and I have been asked by several residents to open a fund to assist in replacing the thousands of panes of glass of greenhouses broken by the hailstones, and in any case of serious hardship occasioned by loss caused by the storm.

I have obtained information that many thousands of panes of glass of greenhouses of our local nurserymen have been destroyed, and the loss to some of our fellow tradesmen, but for the help to be given by means of this fund, is an irreparable one.

This appeal for funds is urgent and is well worthy of sympathetic consideration and very generous support. If any subscriber desires his

of the shrub as I have seen it. With the exception of *O. macrodonta*, generally described as not even hardy in the South of England, I must confess I do not know and have never before heard of the other species mentioned by Sir Herbert Maxwell. Upon reference to a fairly complete list of shrubs compiled from various sources nearly twenty years ago, I find *O. Forsteri*, *O. Gunniana* (Syn. *stellulata*) and *O. Traversii* mentioned as being hardy in the South of Ireland, but no reference is made to either *O. O. nummularifolia*, *nitida*, *ilicifolia* or *semitdentata*—but *O. dentata* is given as a synonym of *O. macrodonta*. These species are probably beyond the reach of the average amateur, even supposing his locality may be suited to their requirements. I wrote only of shrubs that I knew were on the market and easily obtainable.—
EDWARD SHOOSMITH.

[The *Olearias* are as a family much hardier than is often supposed. They might, and probably

called, *Columbus* or *Gala Beauty*, is another omission. A lady bought three bulbs in the distant past and now has a garden full of them, and to show how it flourished sent a sample of the blooms. It is truly a fine Tulip. Its flames of crimson and deep yellow always attract attention. It appeals to me because of its age; if it is not a hundred years old it might be. P. J. Buchoz, in 1781, published a collection of coloured Tulip plates of elephant-folio size, portraying some of the varieties then grown about Paris. French Crown might have been one of them. I once had it, but it never with me had the robustness and power of increase that I like to see in good garden varieties; but, then, I do not live in that Tulip Paradise, the Emerald Isle.

I thought I might be putting my foot into it when I omitted Mrs. Moon, and sure enough I have. It is a fine Tulip, and if at a certain stage of its growth I could give it gin or anything else that might arrest any further development of its flowers I would have certainly included it. It is not content with just "quartering," but it goes on and on until the blooms literally spread-eagle "all over the place." Its rich colour and graceful tall habit do not quite make up for this short-coming.—JOSEPH JACOB.

A SUGGESTION FOR EXHIBITORS!

THE accompanying illustration of a forest pool in Uganda bears a striking resemblance to the Water Lily House at Kew in summer. The three chief plants are *Cyperus Papyrus*, a *Panicum* grass and *Nymphaea stellata* in three colours, red, white and blue. The effect in early morning, before the sun has become too strong, is perfectly charming. All three plants are quite easy to grow in a house in this country, and if they be allowed to rest in winter, very little fire heat need be used. Such a scene lends itself to exhibition, and could have been shown at the Chelsea Show at much less labour and expense than some of the rock gardens there, and how it would have been appreciated by visitors!—E. BROWN.

UTILISING LATE APPLES.

AS all good cooks and connoisseurs of flavour in Apples are aware it is practically impossible to obtain any Apples in May that are not tasteless and sweet, the following hint may be found useful at the present time. If the juice or syrup of a canned Pineapple be added to the tasteless Apples when they are stewed it will much improve them. The Pineapple itself can be used in making fruit salad, to which it is almost always an agreeable addition.—ANNE AMATEUR.

MONOTONY IN GARDENS.

MISS CASE does well to call attention to this matter (*THE GARDEN*, May 20, page 242). During the past few weeks I have had the opportunity of observing hundreds of "front gardens" in the suburbs of Edinburgh, and in two smaller neighbouring towns, and I have noticed more forcibly than ever the sameness and lack of imagination displayed in them with, of course, some few notable exceptions.

The exceptions generally occurred in gardens where a selection of herbaceous plants was employed. Where borders or beds are filled twice a year the choice of variety is obviously somewhat restricted, but so far as my observation goes, much more might be done even with this class of plants. Daffodils were much in evidence, but *Priniceps*, *Emperor* and *Empress* or *Horsfieldii* were almost the only varieties employed. Why not *Pallidus praecox* and *Golden Spur* to start with, also *Sir Watkin*, *Gloria Mundi*, *Glory of Leiden*, *Mme. de Graaf*, *Poiteus*, *Poiteus ornatus*, *P. Poetarum* and *Barri*

A FOREST POOL IN UGANDA.

subscription allotted to any particular case and will so state when sending subscription, I will see that the desire is carried out. Subscriptions can be paid to any local banks, or to me at the Town Hall.—S. PARSONAGE (Mayor), *Mayor's Parlour, Tunbridge Wells*.

THE OLEARIAS.

IN describing these on page 270 as "never very beautiful," I was thinking of *Olearia Haastii*, the only one that is in general and, I think, somewhat common use. I ought, however, to have given its specific name. I can only say that by reason of its stiff habit of growth and its leaf colour of a nondescript green, that is neither blue nor grey, I do not, personally, care for those specimens that I have seen and grown. As with many other shrubs, there may, however, be a difference in stock or type. *Olearia Haastii* always looks to me as if it has been covered with roadside dust, and the flowers have always appeared to me a discoloured dirty white. Therefore, I do not think my verdict was at all "singular." I merely wrote

would, suffer in an exceptional winter, but such as *O. O. stellulata*, *macrodonta* and *nummularifolia* have come through recent winters unharmed in the Midlands of England. All three appear to be as hardy as, if not harder than, the Gum *Cistus* (*Cistus ladaniferus*); certainly much harder than *Cistus salvifolius*, for instance.—ED.]

TULIP SELECTIONS.

IT is impossible to please everybody, which I acknowledge saying is never more true than when it has reference to a selection of Tulips. So it has not surprised me in the least to get three letters calling my attention to some I have left out. (*THE GARDEN*, May 13, page 226.) One said, "Why did you put down *Picotee* and not *Elegans alba*?" and forthwith proceeded to explain how much more beautiful and rehned the last named is. I grant all that was said in its praise as a flower. The thin wire edge of bright rose which never flushes is exquisite, but for the rough-and-tumble of an ordinary garden I still go for *Picotee*. French Crown, or, as it is also

conspicuous, all of them beautiful and cheap varieties! Wallflowers I saw in abundance, but with very little variety. There was little true Vulcan, but for the most part various shades of red, inferior in colour, in substance of flower and in habit to that fine variety. Of that precocious variety Harbinger I saw not one, nor yet of that lovely sort, Sutton's Orange Bedder.

Allow me to record how I furnished a tiny cottage flower border last autumn. I employed Snowdrops, single and double, *Scilla sibirica*, *Iris reticulata*, *Aureola*, *Sisyrinchium grandiflorum*, *Orobis vernus*, Dog's Tooth Violet, Primrose and Polyanthus in variety, *Doronicum*, Daffodil, Wallflower in variety, Lily of the Valley, Pyrethrum, *Campanula persicifolia*, Ox-Eye Daisy, Michaelmas Daisy, *Chrysanthemum*, *Epimedium*, *Montbretia*, Christmas Rose (*altifolius*).

Several of these, though not mentioned were in variety. Of course none could be planted in quantity in such a limited space, some of the larger indeed were represented only by a single specimen. Here, however, is a border furnished at little cost, yielding bloom throughout the year. Perhaps these hints will prove of service to some reader of little experience.—CALEDONIA.

IN MEMORIAM

S. T. WRIGHT.

The red sun flames in the mist-veiled west,
The light of the day is declining
And a light from the gardening world has passed
Which had brightened it long with its shining.

A chill is pervading the evening air
Which the warmth of the day has forsaken
And a sense of loss is lingering there
Since he from our midst has been taken.

Mournful the murmuring streamlet sounds
While sadly the zephyrs sigh,
For the well known form on its daily rounds
No more shall pass it by.

The oaks which knew him for many a year
Their summer array are delaying
While the pale, sweet flowers he held so dear
A sad adieu are saying.

Not unfelt has his passing been
Since not in vain was his living,
For the treasures of knowledge he long did glean
He lavished in cheerful giving.

At the end of its course though a tribute stream
Seem lost in the swelling river
The stones it smooths where its ripples gleam
Will witness its work for ever.

And the spirit of him whose help and cheer
Oft smoothed the troubled brow
Will live in the lives of many here
Whose course is beginning now.

So the light and the warmth that have passed away
Give no true cause for sorrow,
For the place they have sweetly filled to-day
Will be fragrant with flowers to-morrow.

A. E. SIMS.

FLOWERS OF TIBET.

[N "Mount Everest, the Reconnaissance, 1921," by Lieut.-Col. C. K. Howard-Bury, D.S.O., and other Members of the Expedition, lately published, and full throughout of interesting information and speculation, not the least interesting parts are those which incidentally mention the plants which the members of the expedition

chanced upon. It is, of course, not to be expected that in such a work minute descriptions should be given of the various finds. After all, botany was not the first concern of this notable expedition; and so it happens that the notices of various plants, if interesting and suggestive, are also, it must be confessed, sometimes tantalising in their brevity and vagueness, and that, oftentimes, just where they are most interesting. "We found the valley gay with pink and white Spiræas, and Cotoneasters, red and white Roses, yellow Berberis, a fragrant-flowered Bog-myrtle, Anemones and white Clematis." Such charming glimpses as this of the Tibet valley or mountain flora are frequent in the volume, and just full enough to make one wish they were fuller. "A fragrant-flowered Bog Myrtle"? As far as I remember our native Bog Myrtle (*Myrica Gale*), it is the foliage that is fragrant rather than the catkin.

Again, a *Primula* "with three to six bells on each stem, the size of a small thimble, of a deep blue colour, and lined inside with frosted silver." This flower, one of the new finds, I take it, has been named *Primula Wollastonii*, no doubt in honour of the doctor and naturalist of the expedition. Mr. A. F. Wollaston. Again, "Between 11,000 and 13,000ft. you ascend through mixed woods of Pine, Larch, Birch and Juniper, with an undergrowth of Rhododendrons and Mountain Ash. The Larches have a much less formal habit of growth than those of this country, and in the autumn they turn to a brilliant golden colour. The berries of the Mountain Ash, when ripe, are white and very conspicuous." Our own Larches turn to a fairly deep yellow in autumn, and, for brilliancy, our native Mountain Ash in full berry would be hard to beat. But there is certainly room in our British landscapes for a Mountain Ash with conspicuous *white* berries, though just at first it would strike a new and strange note, to which we should have to get used. *Meconopsis horridula* is pretty certain to be known in Kew, and possibly in other gardens as well—"a dwarf blue Poppy which grows in a small compact clump, 6ins. to 8ins. high, with as many as sixteen flowers and buds on one plant; the flowers are nearly 2ins. across and of a heavenly blue." If Kew knows the plant, the sooner Kew makes us all acquainted with this Poppywort the happier we shall be. Where I find the Everest volume most tantalising in its botany is in its notices of the Valley Roses, which notices are sufficiently numerous but invariably omit the specific names. Nor are there any Rose species entered in the list of plants in Appendix V at the head of the volume. We read on one page, for instance, how "We walked up the valley of Rongshar, which in July should be called the Valley of Roses; on all sides were bushes, trees almost, of the deep red single Rose in bloom, and the air was filled with the scent of them." What is this deep red Rose that grows almost to a tree and fills a valley with its perfume?—SOMERS.

"THE FAULT OF THE DUTCH—!"

DOUBTLESS many of your readers enjoy the quaint "English" of the circulars received direct from Dutch nurserymen and are inclined to give a good-humoured order in consequence. May I offer a warning? I sent a small order and cheque to one such firm on March 20 which was duly acknowledged. The goods, however, were not forwarded, in spite of three unnoticed letters of enquiry and protest, in the course of a month. I then cancelled the order and sent in a claim for the return of the cash. To this no reply has been vouchsafed, and even an appeal to the Dutch police authorities has so far proved ineffectual. Moral: Deal at home. SIMPLE SIMON.

FREAK TULIPS.

WOULD you mind telling me through THE GARDEN what you think of the enclosed? During my gardening career of over forty years I have never seen Darwin Tulips throw up five

FIVE TULIPS ON ONE STALK.

flowers on one stem before. As you will see, one has four flowers and the other five. These were growing side by side. I have several others in the same border like them. The bulbs were planted late in the autumn of 1921 in the front of a herbaceous border. The soil is not overgood, and the bulbs have not been disturbed since they were planted. Can you give the name of the variety?—G. S.

[The above letter is typical of a number we have received. Four or five flowers to a stem seem fairly common with May-flowering Tulips this year. This is largely due, no doubt, to the extraordinary weather experienced during the early part of last summer. Secondary "baby" flowers are also very common this year. The name of the variety was in this instance Professor Rawenhoff.—ED.]

TWO INTERESTING PLANTS.

IN THE GARDEN for February 18, just arrived, there is a most interesting article on *Luculia gratissima*. We have a large plant of this in our garden where it is flourishing splendidly; the warmth and the sandy soil suit it well, and we find it does well when once established, though the greatest care is necessary for the first two or three years. Our plant promises to be one mass of blossom this year, every branch and twig having great clusters of buds already showing colour. The delicate pink colour and the delicious perfume of the flowers would make this a favourite everywhere. We have also been very keen in searching the different issues as they arrive for any notes on *Iris tingitana*. Our bulbs of this grow and increase amazingly, but alas! they very, very seldom gladden our eyes by a sight of their flowers. This year we mean to do as one of your correspondents has done, namely, lift and replant some of the bulbs when 7ins. or 8ins. of growth has been made. Perhaps this kind of root-pruning may be just what is needed to check the too prolific growth and to induce the bulbs to throw up flowering stems instead.—ELIZABETH LAW, Wellington, N Z

PLANTS FOR A SMALL MORAINE GARDEN

Being a record of an amateur's experience with such plants in a North country garden.

IN 1917 some notes on above based on my short experience appeared in THE GARDEN. It may be of interest to those keen on the smaller "alpine" to give my further experiences. While most of the plants then mentioned are still in existence, some few have not proved satisfactory, and others have had to be removed owing to their being too appreciative of the conditions provided for them and the tendency to take up too much of the limited space. In the subsequent years many new plants have been added.

All interested in this type of gardening must acknowledge how deeply we are indebted to the late Reginald Farrer for his enthusiastic and illuminating writing on rock and alpine plants and for the zest with which, after exploring most of the best localities in the alpine regions of Europe, he entered into carrying out researches in the unexplored parts of China and Tibet with the purpose of adding treasures to the gardens of those at home only able to travel along with him in the delightful books that made him, to many, almost an intimate friend who will be greatly missed. His death at so early an age in the wilds of Upper Burmah took away one whose influence will be remembered gratefully by the large and ever-increasing number who find pleasure in this more recent development in gardening that has made it possible to bring into our midst Nature's loveliest creations from all parts of the world. Experiments made in their cultivation by Farrer, Clarence Elliott and many other enthusiasts, stimulated to a large extent by their experiences, which they always generously brought to the notice of those interested, in THE GARDEN and other similar journals, and it has been possible to make at home many lovely

plants hitherto deemed almost impossible to grow.

One comparatively recent development is what is known as the "moraine" garden, which had a prominent place in some of Reginald Farrer's

an extensive undulating moraine broken with rocks, more or less after Nature, and sometimes, as in one garden I visited during the war period, very extensive, but the plants (that existed) few and far between. In my own, the moraine is a built-up one with stone sides planted and with a flagged path all round, the object being to make it easily accessible from all sides, to provide room for as many plants as possible, to provide a good depth of cool rooting material and to

ANDROSACE PRIMULOIDES ON THE MORAINE.

books and which was, no doubt, in the first place suggested by the positions occupied by many of the smaller plants in the moraines which are frequent in the various mountain habitats. Moraines vary considerably, depending on individual requirements. Some have moraine pockets in the general rock garden lay-out; others make

bring the flowers into a good position to be seen and examined, and also to minimise as far as possible the depredations of slugs, earwigs and other vermin that are as keen after rarities as the most enthusiastic gardener and even find their way on to the moraine, however isolated and stony it may be. Briefly, it is about 7yds. in length and averages 1½yds. to 2yds. in width. It is divided into three parts at three different levels, varying from 3ft. 6ins. at the high end to 2ft. at the lowest, 6ins. of the depth being below the footpath level. It has an open aspect to the south and south-east and is sheltered from the west and north. I find that the south-east aspect has one disadvantage, and that is that the earlier flowers especially suffer from the early morning white frosts in the spring and early summer, and frequently considerable damage is done owing to the sun getting on to them before the frost ring has disappeared.

When first planting I set out to obtain as many as possible of the fifty best moraine plants suggested by Mr. Farrer in THE GARDEN of May 24, 1913, and forty-three of these I have tried up to the present time. Many additional plants have been obtained, and notes on these will be added in brackets.

Androsaces: *A. primuloides* and *A. villosa*, both plants in the original position and still flourishing. *A. primuloides*, flowering later than the other similar Himalayan Androsaces, usually escapes the frosts; it is a truly delightful specimen in a sloping position on the moraine side, the rosettes usually coming through the winter quite well without protection. *A. villosa* usually has glass protection for a portion of the winter, but if planted in a more vertical position would probably come through without. *A. alpina* (glacialis): a small piece of this gem was tried in the autumn of 1920, but failed to establish itself; it is possible it might have succeeded if it had been protected from the frost, as it was exceedingly wet when and after it was planted.

THE BEAUTIFUL ANDROSACE GLACIALIS "AT HOME."

GARDENING OF THE WEEK

FOR SOUTHERN GARDENS.

The Kitchen Garden.

[Of the other Androsaces, *A. kumginosa* had to be removed, as, although very pretty, it liked the conditions too well and grew too freely for the limited space. *A. Chunhyi*, which was on a flatish part, died out probably for want of protection from winter dampness, although it does quite well outside in a sloping position. *A. sarmentosa*, in a sloping position, unprotected, sometimes looking the worse for its exposure, but gradually recovers and usually flowers well, the flowers, unfortunately, almost invariably being bleached and sometimes killed by early May frosts. It is rather too free for the moraine and does quite well on a wall or in a sharply sloping portion of the rock garden. *A. Watkinsii* continues to prosper; it is of the sarmentosa type with somewhat darker rosettes and deeper red flowers and quite a desirable plant, possibly, however, more suitable for the rock garden than the moraine. Androsace Chametjasme was lost, possibly owing to a specially trying winter and being finished off by slugs. *A. sempervivoides* is another Himalayan with smaller rosettes of sarmentosa type and pretty rosy pink flowers and is the earliest to come into bloom. Being in a somewhat flat position, it is found that some protection from wet is needed in the winter. A carnea flowered nicely towards the end of April, and as the flowers suffer from frosts, a stone was inserted in front to protect it from the early morning sun, which appeared to have had a satisfactory effect.

A. arachnoidea, one of the villosa group with smaller silky grey rosettes, flourishes in a vertical crevice. It flowered well last May and gives promise of doing so again, with its gracefully poised white flowers with greenish yellow eyes which later become pink. It was delightfully pretty in flower and a pleasant reminder of the exquisite gems seen in the Higher Alps.

A. tibetica, recently added from Farrer collected stock from Tibet, is supposed to be of the sarmentosa group, but my plant has much looser and less compact rosettes than any of the Asiatics previously mentioned. It has been partially protected during the past winter, but looks as if it might winter fully exposed in a well drained position. The flowers started to open on April 24, pink in the bud, opening out white or whitish with greenish yellow eye, and it is the first of my Androsaces to come into bloom this very late season, *A. sempervivoides* having hitherto been the first.

A. helvetica, a small piece of what seems to be this species, obtained from a crack on the underside of a large boulder in the Alps in 1920, with small grey-hued rosettes, has established itself and was on May 10 fairly well covered with its small white stemless flowers. It seemed to be "miffing" off owing to damp in the winter of 1920-21, when the idea occurred to me of placing a small piece of broken glass (beer) bottle over it as a protection from wet. This fitted over it nicely without touching the plant and it answered its purpose, the plant duly becoming nice established and, though small, looks quite healthy at present. It has had similar protection this last winter. It is quite probable that *A. glacialis* might have been wintered if similar protection had been adopted.

A. coccinea, an Asiatic species with brick red flowers was exceptionally fine at Kew in June, 1917. It is a plant that I should very much like, but up to the present it has not been included in any catalogue that I have received.

T. ASHTON LOTHOUSE.

[*A. coccinea* though a striking plant is, unfortunately, monocarpic, so is not likely to become popular.—ED.]

(To be continued.)

Endive.—Where a quantity of salading has to be produced for the winter months Endive is almost indispensable. During the next few weeks the main sowings must be made. The seed may either be sown in drills about 6ins. apart and the seedlings transplanted as soon as large enough, or it may be sown in drills 1ft. or 15ins. apart where intended to grow, and thinned out to about the same distance from each other according to variety. Endive appreciates a light but fairly rich soil, and it is particularly advisable to select a well-drained plot for the winter batch.

Potatoes.—The hoe should be used in good time between the rows of successive batches of Potatoes as they become visible, and the earthing up of late varieties be kept well in hand. Where it can be arranged, a dusting between the rows with a suitable fertiliser previous to breaking up and earthing up the soil will be repaid later on. Care should be taken that the soil is not drawn up so tightly round the stems of the plants as to prevent the rains having an easy passage to the roots.

Turnips.—A sowing should be made to provide an early autumn supply of roots. Choose a fairly cool piece of rich ground which must be brought to a fine tilth for receiving the seed. Draw the drills 15ins. apart and thin the plants to 6ins. or 8ins. according to variety and produce desired. It is an advantage to sow several varieties, as some are more prone to run prematurely to seed than others.

Late Peas.—These should, if possible, be grown some distance away from mid-season varieties, where mildew may have obtained a footing. Sow in shallow drills on land which has been well enriched and thoroughly cultivated. The earlier sown plants should have the hoe frequently plied between the rows, and on hot, dry soils it may be advisable to apply a mulching of manure or short lawn grass. The staking should always be carried out in good time and where the Peas are not growing in shallow trenches a slight earthing up is beneficial.

The Flower Garden.

Roses.—A careful watch must be kept for attacks of green fly, caterpillars and maggots. A few good syringings with an insecticide or dustings with tobacco powder will generally get rid of the fly, but hand-picking must be resorted to for the destruction of the other pests. The surface of the beds should be stirred occasionally with the hoe, and during dry spells a few copious waterings should be given newly planted bushes, even if it cannot be arranged for the whole of the plants. Disbudding naturally requires attention where specimen blooms are sought, and it is also to be recommended where the buds are so thick as to prevent a healthy unfolding of the blooms.

Alpine Plants which have passed out of flower should be cut over, and the growth of strong varieties kept from encroaching upon their weaker fellows. Plenty of cuttings will soon be available from many alpinists, including the Aubrietias, Arabis, Perennial Candytufts, Phlox, etc., and all will strike readily in a light sandy compost in a cold frame, which should be kept moderately close and lightly shaded until the cuttings are rooted.

The Hardy Fruit Garden.

Gooseberry Bushes carrying a very heavy crop of fruits should be relieved at as early a date as possible after the berries are large enough for cooking purposes and for bottling. By gathering only the larger fruits it will enable the smaller ones to develop and serve as a more profitable succession than would otherwise be the case. Trees on poor land, particularly those which have to carry their fruits as late into the season as possible, will be greatly benefited by a few waterings of liquid manure followed by a mulch, if possible.

Outdoor Figs.—Any strong water-wood should be removed as early as possible and thus check the tendency to excessive bleeding which the Fig is subjected to when strong shoots are removed. Plenty of space should be allowed the young growths and every encouragement given to a number of growths springing from the base of the tree.

Fruit Under Glass.

Melons ripening should have plenty of warm, dry air circulating in the house and the roots of the plants also must be more carefully attended to, for too much moisture at the roots at this period

greatly mars the flavour of the fruits. Melons are the better, I think, for being kept several days in an even temperature before using them, so it is advisable to cut them before they are too ripe and suspend them in a fruit-room until required.

H. TURNER
(Gardener to the Duke of Northumberland).

FOR NORTHERN GARDENS.

The Kitchen Garden.

Planting Out Celery.—Maincrop Celery should now be planted out at the first favourable opportunity. Where the young plants have been growing on a hot-bed or in boxes of rich material they will lift with good balls of soil attached, so should suffer little by transplanting, more especially if the manure at the bottom of the trench has been mixed with old potting soil or such material as may encourage quick root action. Should a dry spell intervene after planting, copious waterings should be given.

Onions.—Transplanted Onions will now be growing freely, so should be further encouraged by the frequent use of the Dutch hoe between the lines. Where the plants are being grown with a view to obtaining large bulbs, occasional waterings or well diluted liquid manure from the byre should be given. In beds where growth is slow a judicious sprinkling of sulphate of ammonia may also be given, hoeing it lightly in. This stimulates growth and assists in carrying the plants past the stage when they are most susceptible to attacks from the Onion fly.

Cauliflowers.—Early varieties should be assisted with a suitable stimulant, so that no check to growth may occur. Make further plantations of Early London for use in August and Autumn Giant for late cutting.

Coleworts.—Sow seed now for early winter supplies. The ground for this crop should not be over-rich, as the plants should be grown as hardy and short-jointed as possible.

The Hardy Fruit Garden.

Currants.—Bushes of Red and White Currants may be considerably benefited if the shoots are tipped back at this time. More light and air is thus allowed to reach the fruits, while the bushes are also improved in appearance.

Wall Trees.—The various fruit trees on walls should be carefully inspected at this season, and the young shoots sprayed and cleared of insect pests, which if allowed to carry on their depredations will cripple the growths and retard the swelling of the fruits. Where the trees are carrying heavy crops, partial thinning may now be carried out, but discretion must be used in regard to this important work. Young, vigorous trees may be allowed to carry more fruit than others, but on no account should over-cropping be allowed, as this invariably tends towards unfruitfulness in later years.

Strawberries.—Beds of Strawberries which were not manured or mulched earlier in the year will now benefit if given waterings of liquid manure from the byre.

The Flower Garden.

Bedding Out should now be completed at the earliest possible period. The less hardy plants, such as Heliotropes, Dahlias, Begonias, etc., may now with safety be transferred to their flowering quarters.

Genista præcox.—This delightful and free-flowering Broom should receive any necessary pruning immediately it is past flowering. Unlike many other Brooms, this species will tolerate severe pruning.

Hardy Flower Borders.—Staking and tying will necessitate much attention at this season. Weeds will also be more noticeable, and the use of the hoe through the borders now will have considerable influence in lessening the work of cleaning up later in the season.

Biennials.—Seedlings of Sweet William, Canterbury Bells, Hollyhocks, etc., should now be pricked out in a nursery border or into frames which have been cleared of bedding plants. Water well, and shade the seedlings from strong sunshine for a few days.

The "VILLA" SPRAYER

PATENT NO. 161730. BRASS CYLINDER 17 IN. LONG X 7/8 DIAM.

"The Villa" Sprayer is now fitted with a new and greatly improved nozzle.

It is connected to the pump with the same sized screw the old pattern, so that the old one may be unscrewed and replaced by that shown in the cut above.

Instead of the inlet valve being operated by a rubber bag BRASS BALL VALVE has been substituted.

There is nothing whatever to go wrong or to corrode. It is liquid may be sucked up from the very bottom of the can.

By loosening and tightening the brass screw the spraying it may be set to throw the spray at any desired angle, and it is more solidly constructed.

Former customers may be supplied with this new nozzle, post free, 1/6.
Ask your seed-man or ironmonger for the "Villa" Sprayer.

ROSES FOR THE SHRUBBERY

But few of us think of Roses as shrubs, yet shrubs they are.

IT has been often stated and must be freely granted that the generality of garden Roses should be grown in a garden specially devoted to them, quite in the open and unencumbered by herbaceous plants or by other shrubs—for the Rose is a shrub—or trees. Violas as carpeting plants are generally allowed to be innocuous, and Mignonette is frequently tolerated among them, owing to its perfume.

It does not seem, however, to be sufficiently appreciated that these restrictions only apply with any force to such varieties as are used for bedding purposes. Many beautiful Rose species, owing to their habit of growth, show to much greater advantage in the shrubbery than elsewhere, and beyond question the shade afforded to the bases of the plants by surrounding shrubs is beneficial. Nor need we confine ourselves to species in this connexion. Many of the stronger-growing bush Roses and the climbing Polyanthas, of which Crimson Rambler may be taken as typical, succeed better in the shrubbery than elsewhere. Against the shelter afforded has to be set a supposed greater tendency to attack by insect pests—aphides and caterpillars—in such situations. Admitting that what may broadly be classified as bedding varieties of Rose are more susceptible to attack when mixed with other plants, experience shows that with the freer types referred to the reverse is the case. All gardeners with the "bump" for observation have noticed that healthy plants are less subject to insect attack than unhealthy ones, and this, no doubt, accounts for the observed facts in this case. This

notwithstanding, it would probably be wise to keep Roses of whatever type away from related genera, such as the Hawthorns, for instance.

Much has been written about the various wild (species) Roses, of which many are as beautiful as our own Dog Rose, *Rosa canina*, which, if a good form be selected for comparison, is saying a good deal; but there is apparently much still to be said, for these glorious wildings are still not grown to anything like the extent they should be.

It is a mistake to run after alien and, perhaps, not easy species while beauty is waiting almost on our doorsteps. We shall do well, then, to include in our shrubbery the native Sweet Briar, *R. rubiginosa*, of which the fragrant leaves and Dog Rose-like blossoms are familiar to all; or if this be thought too commonplace, we must at any rate find place for some of the beautiful hybrids, most of them raised by the late Lord Penzance. Most remarkable of these, and perhaps

most beautiful, are those raised by crossing the Sweet Briar with the Austrian Briars (*R. lutea*). Such are Lord Penzance and Lady Penzance, for instance, but they lack the abounding vigour of such a sterling hybrid as Meg Merrilees, for example, which is the one which must not be left out. For the front of the shrubbery the Austrian Briars themselves are excellent, since, though not specially free to flower, they form interesting and eyeable clumps.

Closely allied to the Dog Rose, but remarkably distinct from it, is the Central European *R. rubrifolia* (*R. ferruginea*) with red spiny stems and foliage of a singular but striking glaucous-red shade. It is worthy of cultivation for the foliage alone, but the flowers, if small and starry, are a bright rosy-carmine in colour, and the clusters of red hips at once beautiful and striking.

The Scotch or Burnet Rose (*R. spinosissima*) is an easy-doing species which spreads rapidly from underground suckers. It attains a height of 4ft. or so and has a habit of producing an abundance of upright, fine-spined growths, somewhat reminiscent of the Raspberry. The white, rarely pale pink, flowers with their golden stamens are lovely, but rather fleeting. Worth a place in the wild garden, it will be better rather to reserve space in the shrubbery for some of the good sub-species, such as *R. spinosissima altaica* with much larger flowers than the type, often reaching 3ins. across. This is a much larger plant in every way than our native type and needs room. Another very good form is var. *lutea* with bright yellow flowers. Except that it is taller and more upright in

ADMIRABLE FOR THE FRONTS OF SHRUBBERIES, THE SO-CALLED AUSTRIAN BRIAR, *ROSA LUTEA*.

A HANDSOME ROSE—ROSA RUGOSA REPENS ALBA.

THE MUSK ROSE, R. MOSCHATA, EXCELLENT FOR THE LARGE SHRUBBERY

growth, this, to the uninitiated, looks much like the Austrian Yellow, and since it is, on many soils, more accommodating, is to that extent to be preferred to it.

The Rose species most commonly found in shrubberies is undoubtedly *R. rugosa*, and undoubtedly in districts where birds are not troublesome the handsome crimson fruits above the yellowing foliage are very effective. There are, of course, numerous varieties, but readers will remember that the double-flowered forms do not bear the glossy fruits which are the principal ornamental feature of the plant. That wonderfully fragrant, handsome and early-flowering Rose, Courad F. Meyer, owns much *rugosa* blood. It is one of the most suitable Roses for our purpose. The white or nearly white sport, Nova Zembla, is hardly so free flowering, but it also is useful.

One of the quaintest of Rose species and one admirably suited for shrubberies is *R. pomifera* with more or less apple-shaped fruits of shining crimson colouring and of, for a Rose, remarkable size. The flowers, like those of *R. rugosa*, are rather dull in colouring.

Rosa multiflora (Polyantha) is too large for many shrubberies, but, where space can be found for it, is a particularly beautiful species with white flowers borne in clusters. This is the parent, or perhaps it would be more truthful to say a parent, of all the climbing and dwarf Polyantha Roses of our gardens. The climbing Polyanthas succeed admirably in the shrubbery, even in a tangled one, and strangely enough appear to suffer much less from drought there than when trained on a pergola or to poles in the rose garden.

Some of the best Polyantha Ramblers for the shrubbery are Crimson Rambler (or Philadelphia Rambler, if that is preferred), Blush Rambler, Carmine Pillar—this is especially excellent so treated—and Aglata. That beautiful white Rose, The Garland, also is excellent, and though classed as a hybrid Musk, probably has *multiflora* blood.

The Musk Rose itself, *R. moschata*, is admirable where space can be afforded it, but it is a large grower and needs space to show itself to advantage.

Rosa macrophylla, with rosy-red flowers, and *R. Moyesii*, with deep brownish red blossoms shot with fiery crimson possess many points of similarity. Both have brilliant fruits, curiously constructed at the junction of the fruit proper with the persistent sepals, which give them a bottle-like appearance. Both are elegant growers with arching wand-like canes and handsome foliage, but *R. Moyesii* is more slender in habit and smaller in leaf than the other and longer-known species.

In *Rosa Hugonis* we have another species, suitable on account of its size and spreading habit only for the large shrubbery. Generally considered the best of the yellow-flowered species, it has beautiful foliage, but the fruits unfortunately are black and uninteresting, which is characteristic of all the species allied to *R. spinosissima*, which *R. Hugonis* obviously is. The creamy-white *R. hispida*, also of this family, has bright yellow buds. It is at once uncommon in gardens and ornamental.

It is necessary always to keep in mind the distinction between Roses such as the Austrian or Scotch Briars, which are bushes in themselves and need spacing accordingly, and *Rosa multiflora* and its hybrids, for instance, which like to grow between and throw their trails over other shrubs. There is room for both classes in the shrubbery, where late-flowering sorts are especially valuable.

SOME BEAUTIFUL GENTIANAS

THE Royal Horticultural Society might do worse than undertake the classification and nomenclature of the genus *Gentiana*. There is certainly much confusion in nurserymen's lists for which, as a rule, the nurserymen are not to blame, though a certain "boosting" of supposed new

the so-called pink *Gentian*, *Erythraea diffusa*. *G. bavaria* is probably more difficult to grow than *G. verna*, though not everyone has found it so. Outdoors treatment similar to that recommended for *G. verna* affords the best chance of success, but an abundance of moisture is essential.

G. pyrenaica, when it is obtained true, is an excellent moraine plant with well rounded flowers of a rich deep blue colour, but without the startling brilliance of *G. gentianella* or *G. verna*. *G. punila*, another excellent and not difficult species,

distinctly brighter in colour than *G. verna*. Unlike that species, it grows into compact tufts or mats of foliage. Though its range in the Alps is higher than that of *verna*, many find it easier to make happy in the moraine.

Turning now to the taller and more leafy species, the huge *G. lutea*, from the root of which is obtained the bitter principle so excellent as a tonic, is in its native fields a remarkably handsome plant, so handsome that it might well be tried in cool, rich soil in the wild garden. It is fairly easy to raise and rear from seeds. The related *G. tibetica* calls for mention only as an ugly weed to be avoided. The Heath *Gentian*, *G. Pneumonanthe*, is an indigenous plant and interesting on that account, and, although not showy, is worth trying to establish in cool soil with an abundance of humus. The Continental form called *G. P. arvensis* is much larger and somewhat more showy.

The Willow *Gentian*, *G. asclepiadea*, is, if a good form be obtained and given good culture—it likes a rich deep soil and a cool exposure—a wonderfully fine species for wild garden or border. Its flowers in the better forms have that gloriously rich hue known to gardeners everywhere as *gentian blue*. *G. septemfida*, somewhat in the same way but a much smaller plant, has conspicuous, well opened flowers of a beautiful soft blue. This species also likes a cool root-run in rich, rather peaty soil. *G. Lagodechiana* is merely a dwarf form of this species, but a very desirable one. The beautiful *G. Freyudiana* again is closely related and requires similar treatment.

There are several other beautiful *Gentians* with which the writer has had no successful experience, but he will end these brief notes by mentioning a few weedy species which should be shunned. Such are *G. G. brevidens*, *Cruciata* (this is better than some), *dahurica*, *decumbens*, *Fetisowi*, *Kesselringi*, *macrophylla*, *Olivieri*, *punctata* and *Walujewi*, with the already mentioned *tibetica*. If experimenters with this genus note only the list of rubbish—generally speaking, easily grown rubbish—these notes will not have been written in vain. H. H.

GENTIANA VERNA AS A MORaine PLANT.

species is noticeable in some quarters which are, in fact, not new at all—though new under the name given—and of small beauty or interest.

From a garden standpoint the most valuable species unquestionably belong to the *acaulis* group so admirably described recently (*THE GARDEN*, March 11, page 113) by M. Correvon. It would be stupid to traverse that ground again, but the interest aroused by the article was such that some notes on other desirable and *growable* *Gentians* may not be out of place.

No plant, probably, has occasioned greater controversy as to its culture than the altogether delightful *Gentiana verna*. It unquestionably likes a damp climate, and that, outdoors at any rate, many of us cannot afford it. It certainly does not appreciate bare earth around its rosettes, nor, considering its method of growth in Nature, would one expect it so to do. It is advisable therefore to associate it with some light-growing carpeter, such as the native *Arenaria verna*, for instance. For the rest, moisture at the root and to a lesser extent in the surrounding air can be given by planting it in the moraine. A westerly exposure is, in the writer's experience, best. There are many forms of this plant (leaving quite aside colour forms), and it is worth while to select one with stout, well rounded flowers, but freedom to bloom is an essential point and one often overlooked.

Gentiana bavaria is perhaps even more beautiful than *G. verna*, with a depth in the colouring and finish of the flower which renders it quite distinct, apart from the more slender habit of growth, the paler, much less displayed foliage, and the absence of basal rosettes. The leaves of *G. bavaria*, indeed, get larger as they near the top of stem, being reminiscent in this respect of

might be described as a minute and dark *G. verna*, but the leaves are narrower, more rigid and grass-like. *G. brachyphylla* is rather smaller and

BASKET BEGONIAS

Their Value, Culture and Present Propagation

THOSE who appreciate the most beautiful and artistic effect from their greenhouses and conservatories are always on the alert for charming plants that can be suspended from the roof in baskets. And in this connexion I know of few plants which are capable of giving greater satisfaction than the pendent *Begonias*, for they possess every virtue and no vices, are graceful and varied in form and colouring, easy to grow and to manage, enjoy remarkable immunity from pests, and flower brilliantly and continuously month after month. In winter they can be safely stored away in a frost-proof place while other varieties—in the form of *B. Gloire de Lorraine* and its relatives—take up the story and "carry on" all through winter and spring, until their tuberous brethren are again ready to occupy the place of honour.

Enter through the doorway of a house in which basket *Begonias* are well represented and—however brilliantly the staging may be furnished—you will find your eyes irresistibly drawn upwards to the flaming colour masses that hang overhead. Yellow, carmine, salmon, pink, deep red, orange and scarlet, all are there, and all flowering with the profusion to which we are accustomed on the staging, save that these flowers are in an infinite

variety of form and are borne on long pendulous stems full of grace and lightness.

Culturally, the tubers are started in precisely the same way as the ordinary tuberous varieties and left to grow on until about June, if top growth has been made, when they are ready for placing in the baskets.

Where named kinds are used, one tuber in an 8-in. basket is sufficient, though a better effect is obtained where a 10-in. basket is used with three tubers set in a triangle. Great interest attaches to unnamed seedlings, however, and where a number of these are on hand, half a dozen can go into an 8-in. basket for the first summer, although in subsequent years these make much more vigorous tubers than the named kinds and consequently require more space.

A mixed packet of the hybrids of *B. Lobli* will provide a wide variety of colours, and in the second and succeeding years a single tuber of these is sufficient to furnish a full basket.

Baskets which are to contain tubers must first be well lined with fresh green moss, carrying this right to the top, and then filled with soil. The moss should not be spared or the soil will wash through it when watering has to be done. Make the soil firm and let this consist chiefly of turfy loam. Deep planting is a mistake, the

THE PICTORIAL ROSE GARDEN

tubers should only be just hidden from sight. Water thoroughly when planting is finished and hang the baskets in a house where the temperature ranges between 60° and 70°, keeping the atmosphere well moist by daily syringing. While the roots must never become dry, a sodden condition of the soil quickly brings the plants into an unhealthy condition. Too much or too little moisture will at a later stage bring down the buds in showers.

Basket Begonias are often far too heavily shaded. Scalding sun they will not stand, but a light screen only is necessary to protect the foliage from harm, and there can be no question that they flower much more freely where a good supply of light reaches both buds and stems. A common mistake is permitting the plants to flower before they have well furnished the baskets with growth. Remove all buds as they appear until plenty of vigorous growth has been made; the flowering will then take care of itself. Among named varieties I can confidently recommend the following as first class in every way. Alice Manning is a lovely clear yellow, splendidly free, fully double, and forming a perfect shower bouquet of loveliness. Carminea cannot be accused of heaviness. It is light and graceful and a fine carmine red in colour. Corallina is a distinct salmon pink, the blooms being especially pretty by reason of their long pointed petals. Fleur de Chrysanthème is one of the best named species for making a display of colour. The habit of growth is all that could be desired, while the profusion with which the salmon pink flowers are borne is little short of marvellous. Gladys is another "all flower" variety, very double, with long, narrow petals of rich dark red. The foliage of this, too, is long and narrow, just the best possible complement to the pendulous masses of flowers. In bright crimson Lena is a distinguished variety with attractive, loosely formed flowers, the abundance of which leaves nothing to be desired. Marie Bouchet, owing to its great vigour and the length to which the long branches extend, is suitable only for really large baskets and where space permits of their being hung. In the large conservatory it is superb with a profusion of handsome deep red flowers. As a contrast to this for the small house Mrs. Bilkey (orange salmon) is worthy of high praise; indeed, next to Lloydii it is the most desirable of all, as, while giving glorious balls of colour, it is not too rampant. The name Rose Cactus is aptly descriptive of this showy form. The plant simply smothered itself with a wealth of bright rose cactus-like blooms with very elegant pointed petals. For bright scarlet red Sirius will take some beating; indeed, it is, so far as I have seen, the premier variety in this colour. Stella (another red) is first class as a basket plant, and is distinctive in the pretty form of its flowers, the narrow petals of which are curiously curled and twisted.

When propagation of any of the above is contemplated it should not be left too late in the season. This is an excellent time for detaching the cuttings, which when taken off at this time form nice little tubers before the advent of autumn inhibits further expansion. Cuttings are not difficult to root, provided the watering is in skilled hands. Sever these just below a joint and remove the lower leaves with a sharp knife, then insert in pots filled with light soil so that the base of each cutting rests upon a small heap of sand. Water so that the soil is never more than just damp, but keep the atmosphere well moist so that the foliage does not droop. A close propagating frame in the greenhouse is an ideal place for the cuttings, gradually accustoming them to more and more air until fully rooted, when they should at once be given single pots and be grown on as rapidly as possible. H. W. CANNING-WRIGHT.

THE rose gardens on the Riviera have been unusually beautiful this season, partly because the month of April was so cool that the blooms opened more slowly and lasted longer, and partly because the bushes had rested so long and so completely, owing to the absence of the usual autumn rains. In consequence of this, no Roses were pruned last winter, and this absence of pruning, coupled with the long rest and thorough aeration of the soil, produced the most splendid harvest of bloom—richer in colour and larger in size—than any season I can remember. It will be interesting to see if there is anything of the same sort visible in English gardens this summer.

We certainly are apt to over-prune our Roses in England: we love our trim rose gardens with their neat bedded-out masses of flowers hardly taller than the geranium beds they have replaced, and no doubt quite as brilliant in colour in many cases; but is it not a fact that one often hears a friend say: "My rose beds are quite worn out and must be renewed"? The truth is many of these gardens are too neat, the Roses too closely pruned in spring, and, what is worse, the Roses in summer are cut with such long stems that the growth of the plants is seriously weakened. You cannot always be cutting your Roses back if you wish to make or keep them vigorous, and the bedding Roses should be lightly shorn of leaf or flower during the summer.

On the Riviera the Rose bush is all the better and more vigorous as the years go on, and a twenty year old bush will produce hundreds of flowers each year—often twice yearly on bushes that are allowed to grow at their own sweet will and are not cut down to ground level each winter. There was a charming picture the other day in THE GARDEN of Rhododendron bushes in rough grass, each covered with abundant heads of flower. I showed it to a friend, who said at once: "Why, without my glasses I should take this as a picture of the Rose bushes in your valley!" and it is no exaggeration to say that Rose bushes on the Riviera should be as big and as full of flower as any Rhododendron bush in England.

It is not every Rose, however, that is suitable for the pictorial rose garden, and that is where comes the "rub." We see so many beautiful Roses at a show that we are possessed with the idea that they are the Roses needed for the garden of our dreams. It is true they may be so, but you have to prove them. Especially is this the case on the Riviera. Roses budded on the Briar stock are sure to suffer in a really dry, hot season; while the Indica major and De la Grifferaie stocks do not suit many Roses, notably the brilliant Pernetiana Roses, which prefer a moister climate at all times. Travellers all delight in the cascades of Roses seen tumbling over the garden walls or climbing high in the Olive trees, not one of them probably is less than twenty or thirty years old, and if ever grafted (which I doubt) has long ago made root for itself and left the stock to pine away. So, then, the Roses you wish to depend upon for your pictorial garden should preferably be on their own roots, and patience will be needed for a year or more. On the Riviera we have a number of Tea Roses raised years ago, chiefly by the Nabonnand family, that are quite indispensable on account of their vigour and freedom of bloom, especially in winter, when Roses are doubly precious and doubly delightful because they last so long in the cool atmosphere. In the more northern gardens, and especially in England, the Hybrid Tea Roses are the mainstay of any rose garden, but many of them have not the same

vigour of growth as the Tea or Bourbon Rose, and I leave it to those who cultivate them best to say which are the most pictorial in growth and habit, for it is the *free-growing* Rose that I wish to champion, and it is the permanent and pictorial rose garden at which I aim. There, if need be, pruning may be left alone now and again, when the seasons are kind, so that Roses may have the chance of showing themselves in full beauty. To show off such Roses an Olive tree or two and quite a sprinkling of Orange or Lemon trees are needed to give background and shelter from sun and wind. That entails irrigation in summer, as the Orange and Lemon trees must be kept green and growing. So, then, the pictorial rose garden must be where water is at hand, whether on the terraced hillside or on more level ground. I need say nothing about the necessity of planting the familiar Banksian Roses of all types, or of the Japanese *Rosa sinica* and its lovely hybrid Anemone, or of that lovely but uncertain Rose, Fortune's Yellow, for they must be in every garden.

I am now mentioning the strongest growers and the best winter bloomers. Noëlla Nabonnand (deep red), Comtesse de Turenne (pink, Bourbon), Dr. Rouges (red), Duchesse de Nemours (bright pink, Bourbon), Lamarque (lemon white, Noisette), Mme. Alfred Carrière (flesh white) Beauté de l'Europe (buff yellow), M. Choutet (orange and yellow) and M. Calvat (pink, Bourbon) are all of the greatest vigour and beauty and should be used for arches, climbing up trees or posts, or a wall, if there be one.

Not many Roses succeed on a south wall, but Lamarque and Noëlla Nabonnand seem to "stand" anywhere. Then comes a slightly less rampant group, most useful for cut bloom in mid-winter, of which Peace and Warrior are almost invaluable. Peace is either a seedling or sport of the good old G. Nabonnand (still one of the best) and its blooms open in cold weather as well as did the old Safrano, now discarded, and its lemon cream tones are always welcome. These Roses (and many others) need either a pole or an espalier to show off their best points. There is a new American Rose named Hadley, deep red in colour and very fragrant, that promises to come under this category.

Then come the ever-welcome bush Roses, which should in time attain 8ft. or roft. in height and as much through. These are the mainstay of the more formal part of the garden and should be planted in groups of three so as to make more effect. After many years experience I unhesitatingly give the first place to the rose pink General Schabliakine and the creamy Antoine Mari as the most dependable of all winter Roses. Comtesse de Leusse, flesh pink and very hardy, and Archiduc Joseph, more stiff and sturdy, if possible, and varying in colour from pale to deep rose pink, come next as indispensables. There are many others nearly as good, and local conditions bring them into the first rank sometimes, as I have seen, but the list would be so long I dare not go on with more names; but I must remark, *en passant*, how few good yellow roses are to be found in winter, and I regret not to be able to recommend the good old Maréchal Niel or the still lovely Chromatelle without a word of apology for their uncertain behaviour. Will some good man give us a Rêve d'Or that shall be worthy its name? How welcome it would be! It is amusing sometimes to bud a new Rose on a strong shoot of any of these free-growing Roses—sometimes it is a great success. A hedge of Roses can be agreeably varied by such a proceeding. E. H. WOODALL.

THE ESSENTIALS OF GOOD GARDEN DESIGN

I.—Simplicity and Directness.

AGARDEN designer must, if his work is to be worth while, have good taste, but the possession of that elusive quality will not of itself make a garden designer; or, indeed, a designer of any kind, for between the appreciation of what is good and fine and the power to design or construct such there is a great gulf fixed. The professional garden designer, or garden architect as he is now generally called, has, or should have, over the amateur who designs his own garden, the great advantages of much experience and a prolonged study of various styles and traditions. This notwithstanding there will always be numbers of people who will wish to design their own gardens, and it is largely for their benefit that these notes are penned, though many who would never venture to carry through their own designs may probably find them of interest.

The amateur designer has usually one advantage over the professional in that he can, if he has patience, bring an amount of thought to bear upon the matter in hand which a garden architect could hardly be expected to give. Such thought is especially valuable in that it may suggest ways of using to the best advantage existing features—clumps of trees and what not—ways which would at first sight elude one. Even this advantage, however, should not be unduly magnified, for it must be granted that a trained observer will see and absorb in a few hours what it might take an amateur weeks or months thoroughly to appreciate. If the amateur designer is a keen gardener of long standing, he may perhaps have a better knowledge of trees and plants and their possibilities than, at any rate, the average garden architect, and this knowledge he should turn to full account.

The veriest novice can usually distinguish a garden designed by the garden owner from one

laid out by a garden architect—even by an architect of middling ability—though he would perhaps be puzzled to state wherein exactly lay the difference. The failing of the architect's garden is apt to be monotony, that of the amateur's complexity, hence the need of these notes upon simplicity and directness.

Want of simplicity is manifested in a multitude of ways, as, for instance, in the indiscriminate dotting of little beds in a lawn where a stretch of unbroken greensward or a stretch broken only by a bed or group of beds would have been at once simpler and more restful. Again, how often does one see a path that obviously winds hither and thither merely for the sake of winding, and how fatuous such a path always looks! A straight path or a path in one strong yet beautiful curve would in such case be infinitely better because of its straightforwardness and simplicity. Generally undue complexity leads to the compressing into a given space of more detail than the space will properly display. Paths and vistas accordingly are apt to be too narrow to be effective, and in other ways want of simplicity is apt to strike the eye as meanness of proportioning.

A good and restful garden need have scarcely any ornaments, but those included should certainly be good of their kind, bearing in mind that goodness and expensiveness are not interchangeable terms. A Venetian well-head and a simple modern potter's urn may be equally good each in their separate ways and as fitting for your garden, especially if it be a small one, the urn may conceivably be the better as being more suitable, both in scale and material, to its surroundings. Observe, however, the essential difference, apart from design, between the good and the bad. A terra-cotta urn that frankly is that, may be very pleasing; but a terra-cotta vase that makes believe to be stone is an

Fig 1.—Two Rose-bordered paths. On the left a meaningless wriggle. On the right an example of simple, sound design.

imposture. It may fill the eye from a distance, but when, drawing nearer to inspect what one admires, one discovers it to be a fake, nothing but dissatisfaction is left.

This question of ornaments is responsible for much of the feeling of complexity with which so many gardens impress one. An ornament may be intrinsically beautiful and yet be quite unfitted to your garden or to mine. What we need is something right, not only in feeling but in *scale* for the place into which it is to go. Well-heads and sundials in the medium-sized garden are,

Fig. 2.—Treatment for the garden-front of a house rather awkwardly circumstanced as to its boundary. Note the absurd curves of the surrounding shrubbery, the (usual) round Rhododendron bed, and the ugly and distracting little beds in the foreground. Yet this illustrates a by no means exceptional treatment.

Fig. 3.—A simple treatment for the same site, in which the offending waves are abolished and the beauty of the grass setting is allowed play. The bed at left hand top corner would be filled with dwarf-growing shrubs in keeping with the shrubbery behind and the balancing trees on the right might be under-planted with Heaths, *Genista hispanica*, etc.

IRISES AND SUMMER FLOWERS AT VINCENT SQUARE

experience shows, apt to be over-large—though there is a wide range of small sundials always on offer—while garden seats and bird baths, on the contrary, as often seen are ridiculously small. It is difficult in a small garden not to get the summer-house too large to make a good ending to a vista, but it is amazing sometimes to hear, as one often does hear, "We hope some day to put a summer-house there to close that vista," and then to see the seat which, pending the provision of the summer-house, they have set to close the vista in its place. If a vista cannot be closed worthily and weightily by garden furniture, much better let it terminate in a half-circle of solid English Yew.

A notable example of want of directness in treatment is to be seen on the garden front of the new laboratories at the R.H.S. gardens at Wisley, where the terrace, falling from end to end, is quite unnecessarily broken and the steps suffered to meander in a way which is not only distracting but which actually breaks, by the interposition of a wall parapet, the line of vista; all quite unnecessarily.

Much restlessness and complexity is introduced into gardens because of a desire to have something different from other folk. The personality of the garden-lover will surely stamp its mark upon the garden, and that quite unconsciously. The seeking of the merely bizarre to provide a difference is as unnecessary as it is disturbing. Where natural rather than formal gardening is desired or is appropriate it might appear that the resolute quest of simplicity is no longer essential, yet actually in no form of garden lay-out does one need more steadily to keep one's eyes upon the light. Breadth and simplicity are, in fact, the very keystones of successful natural gardening, though it is true enough that such work is not simple to carry out effectively. The amateur has, however, this consolation that working with living material he may largely alter season by season the living picture he is painting until he moulds it "nearer to his heart's desire."

Estates laid out by "Capability" Brown or such parts of them as still bear evidences of his handiwork—have sometimes a dignity and beauty worthy of emulation. It is rather doubtful, however, whether this is not rather evidence of Nature's triumph over mediocre design rather than any special goodness in the design itself. Be this as it may, it is certain that Brown's ideas of garden arrangement are quite unsuitable, not only for small gardens, but for any gardens of a size likely to be constructed to-day. Present-day taste certainly rather favours the formal in garden making, but the formality should not be over-emphasised by undue restraint on the liberty of growth of the plants used.

If there is anything worse in modern gardens than the succession of aimless serpentine paths—sometimes seen it is the serpentine curves which but too often, form the outline of lawns. Usually a very little thought will show how these may be altered, nor need it as a rule be a difficult matter.

The popularity of stone paving is understandable, since it forms an excellent dry path and is, especially if it takes the form of self-faced hard York stone, exceedingly pleasing in itself and even more pleasing as a splendid foil to many plants with flowers or foliage in shades of purple, crimson, soft yellow or grey. There has, however, sprung up of late years a tendency to use what is called "crazy" paving—often with hideous gaping joints—even for formal paths and terraces. This tendency can only be described as retrograde. It reminds one of the strange fancy which existed a generation ago for "rustic work," rooteries and other monstrosities.

It was very largely a show of Irises at Vincent Square on June 7 and 8, even though the hot, dry weather had so hastened the blooming of so many varieties that the selection of types to illustrate the proposed classification

of Irises was not so valuable as was hoped. But the great trade growers were able to set up magnificent collections of many types and their great excellence may be judged by the fact that three gold medals were awarded to [collections. These were by Messrs. Barr and Sons,] who arranged their [great array in a most attractive manner; to Mr. Amos Perry, who had his gorgeous Irises rising from a cool green bank of his admirable hardy Ferns; and to Messrs. Wallace and Company, for such an extensive and valuable collection that the "congratulations of the Council," the latest and most valued award of the Society, were added to the gold medal.

Although it did not contain so many flowers as in their entrancing Iris garden at Chelsea, the collection of Messrs. G. Bunyard and Co. was very attractive and particularly rich in varieties of the showy Iris squalens section. At the other end of the hall Messrs. G. G. Whitelegg and Co., Limited, had a valuable collection of Irises, in which the yellow and carmine-bronze Iris King, the lavender shaded Tamar, the yellow Mrs. Neubronner, and many others were very prominent. Of the many sorts in Wallace's collection, Isoline, lavender bluish with rosy lavender falls; Souvenir de Mme. Gandichau, the deepest and most velvety dark blue Iris in the show; M. Boyer, a good spike of metallic purple standards and rosy purple falls; Ambigua, of delightful reddish carot and maroon shading, were especially charming.

In Messrs. Barr's artistic group there were stately spikes of such pallid varieties as Crepuscule, Albert Victor and dalmatic Princess Beatrice. Chief among the Iris squalens sorts were Mary Garden, Eldorado, Le Réve and Quaker Lady. Besides these and many more of similar types, they had some excellent varieties of giant Niphium Irises and Ixia Humbert and Scarlet and Gold. A smaller collection by Messrs. Lowe and Gilson, who can grow Irises equally as well as they do border Carnations and Auriculas, included beautiful spikes of Dora Longden, Eldorado, Prosper Laugier and, best of all, Camelot, a chaste Bliss seedling with milk white petals lightly feathered pale lavender.

Such Irises as Fro, of golden and bronzy-carmine colouring; Isoline, pale shades of purple; Princess,

a dainty lilac bluish, and Ed. Michel, royal purple, with bright lines at the base of the petals, were pleasantly associated, by Messrs. Waterer, Sons and Crisp, with goodly masses of the Golden Sunshine Beauty Lupin, Delphinium Lamartine,

ONE OF THE NEATEST OF SUN-ROSES—HELIANTHEMUM ROSMARINIFOLIUM.

Achusa italica Dropmore variety and some tall spikes of Eremurus.

The bulbous Irises were represented by two interesting collections in addition to the Niphium varieties in Barr's collection. Ryders had a number of very good Dutch Irises. Those of blue shades included Imperator and E. B. Garnier, while, of the whites, D. Haring, White Excelsior, and A. L. Koster were chaste and beautiful. Messrs. Chapinan, Limited, set up some of their Rotherside Irises which are said to be crosses between Iris tingitana and Spanish varieties. They are early flowering, of good size and in a pleasant variety.

There was an Iris Conference during the afternoon and in order to assist in the work of colour classification the Society had brought from Wisley flowers of many classes and types, but the season prevented this being as full as was wished. The three or four competitive classes found ample space in a part of the Orchid annex. The best exhibit from every point of view was the collection of twelve varieties by Messrs. Wallace and Co., which won the prize offered by the American Iris Society. These were

all varieties in commerce and included handsome spikes of Ma Mie, Medrano, Proserpine, Isoline and Ed. Michel. Mr. Baker was a good second in this class.

The prize for the best three spikes of one seedling was awarded for Chasseur, by Messrs. Vilmorin-Andrieux. It is a free flowering sort, mostly yellow in colour; the falls are paler than the standards and have rosy-carmine markings at the base. It cannot be said to be a beautiful flower. Mr. A. J. Bliss won the other two first prizes. Only two of his three seedlings were on view and these were Swazi, a purple shaded Iris, and Citronella, which was the most beautiful Iris in the hall. It is much of *I. squalens* type and the golden falls are heavily lined with carmine which is enhanced in beauty by the golden beard. As a single spike he showed Bruno, a rich purple shaded flower of magnificent size and shape. Many judges thought this should have taken first prize over Chasseur in the class for three spikes of a seedling Iris.

Besides all these gorgeous and beautiful Irises, there were sufficient general flowers to interest all tastes. Richly coloured sprays of such Roses as Persian Yellow, Star of Persia and Harrisonii, were shown by Mr. George Prince and the Rev. J. H. Pemberton, while *Rosa grandiflora*, *R. Moyesi* and *Pax* were also noteworthy for their grace and beauty. The usual collections of bright and fresh Carnations were shown by Mr. C. Engelmann and by Messrs. Allwood Bros., who included a good selection of their graceful Allwoodii. Messrs. John Peed and Son, staged an excellent collection of Streptocarpuses, greenhouse plants that are of very easy cultivation if given light shade and

atmospheric moisture. These plants were all large-flowered hybrids and unusually free flowering for that type. They also had four double Petunias in rose, blue and white.

Bastin's strain of double-flowered tuberous Begonias were also extra good and the new variety Lady Bell was particularly charming.

Although hardy flowers, the Sweet Peas shown by Messrs. R. Bolton and Son, and the Antirrhinums by Messrs. Dobbie and Co., had all been grown under glass, and they both were especially fine. There were several new Sweet Peas of Bolton's raising. *Comdale* may be termed a bluish rose Picture, for it is very like that beautiful sort in form and habit. *Elsie Dean* is a silvery lavender self and is certain to be in request, as it is a great advance on all previous lavender coloured Sweet Peas. *Wonderful*, a glowing scarlet, and *Orange Flame*, of very orange colour, are both said to be sun proof. *Artistry* is a greatly improved Princess Mary. Among the Antirrhinums we noted a vase of the old striped Antirrhinum which is rarely grown in the south, but is in high favour above the Tweed. At the shows in Edinburgh, Glasgow and Dundee there are often as many as twenty exhibits in the class for six vases of distinct colours, and the fanciers are very critical over them. The self colours of such as *Coecinea*, *Yellow King*, *Cottage Maid* (one of the best pinks), *Amber Queen*, *Maive Queen* and *Maize Queen* appeal much more to the southern taste.

Lupins were very prominent among the border flowers. Mr. Clarence Elliott had a splendid strain of scented *Lupinus polyphyllus*, and Mr. R. G. Downer showed some very strong spikes,

though they were not scented. A charming strain of long-spurred Aquilegias was shown by Mr. V. C. Vicars of Newsell's Park, Royston, who grows over 9,000 plants and staged some sixty very charming varieties. Among several brilliantly coloured Heucheras, Mr. G. W. Miller staged *H. narelloides*, a graceful, feathery, soft pink variety; while Messrs. B. Ladhams, Limited, had many charming and fragrant garden Pinks in their collection of border flowers, and Messrs. Maxwell and Beale showed the uncommon *Lavandula Stochas* and several of the *Mesembryanthemums*, which flourish in warm, sunny places. *Apuga Brokbanki*, shown by Mr. M. Prichard, bore many sturdy spikes of intense blue flowers. Another extra good dwarf blue herbaceous plant was the *Veronica Shirley Blue* of Messrs. Ladham's collection. Especially pleasing was *Helianthemum rosmarinifolium*, starred with silvery flowers, on Mr. Clarence Elliott's exhibit.

The most showy of all the trees and shrubs were the sprays of the rosy purple pea-shaped flowers of *Robinia hispida macrophylla*, with the somewhat similar *R. Kelseyi*, shown by Messrs. J. Cheal and Sons. Mr. Charles Turner had several very interesting shrubs, such as the sweetly scented *Syringa Swegnizowii* and *S. Enodi*. *Dentzia hybrida Lemoinei* may be termed a greatly improved *D. gracilis* and it is an excellent pot plant for gentle forcing. Mr. Turner also had flowers of *Magnolia Delavayi*, which are deliciously fragrant. *M. Watsonii* and *M. parviflora*, two other desirable creamy-white flowered Magnolias were to be seen in Mr. G. Renthe's collection of shrubs and alpines and he also included brilliant spikes of

A MOST STRIKINGLY COLOURED BEARDED IRIS,
CITRONELLA.

DIANTHUS x MASCOTT, A HYBRID BETWEEN SWEET WILLIAM
AND CARNATION.

Habranthus pratense. The fragrant early Dutch Honeysuckle was shown by Messrs. Hillier and Son, with several good *Cistus*s, *Abutilon vitifolium* and other species.

In a corner space Messrs. Blackmore and Langdon had a collection of splendid *Delphiniums* in great variety, while at the other end of the hall Messrs. Kelway also had some *Delphiniums*, but their beautiful *Pæonies* were the greater attraction. An admirable collection of double and single-flowered *Pyrethrums* was shown by Mr. W. F. Gullick.

NEW AND RARE PLANTS.

Begonia Lady Bell.—A very uncommon and beautiful tuberous *Begonia*. The broad stout petals are prettily frilled and it is a fully double flower of fine shape. The colour is deep creamy white and the margins are of soft orange. The marking is much like that of a heavy edged *Picotée*. Award of merit to Messrs. Blackmore and Langdon.

Buddleia alternifolia.—This appears to be a very graceful and free flowering species. The alternate, lanceolate leaves are about 2 ins. to 3 ins. long, pale green above and silvery below. The very long flowers are somewhat of *variabilis* type, but the raceme is not branching at the base. The flowers are of silvery lavender colour and slightly fragrant. Shown by Sir H. J. Veitch.

Catalpa Fargesii.—A handsome tree, 20 ft. to 30 ft. high, which was first discovered by Père Farges in Szechuan, China. Wilson found it in W. Hupeh, Western China, in 1907. The broadly ovate, soft green leaves are much smaller than those of *C. bignonioides*, but the flowers are about the same size. They are spotted with pink and brownish red and have bronzy orange markings on several segments. Shown by the Hon. Vicary Gibbs.

Dianthus Mascott.—A sturdy and uncommon hybrid, much like a large flowered Sweet William, though the flattish heads are rather looser in habit. The deep pink flowers are delicately scented and have a small pale eye. It was raised by crossing Sweet William Scarlet Beauty with a single *Carnation*. Award of merit to Messrs. Ireland and Hitchcock.

Euonymus Wilsonii.—This bushy species, which was discovered by Wilson on Mount Omi, W. China, has coriaceous, serrated, dark green leaves and bears quantities of greenish flowers. Shown by the Hon. Vicary Gibbs.

Gloxinia Bacchus.—A very distinct, erect flowering variety which bore plenty of large, perfectly formed, very deep crimson coloured flowers. Award of merit to Messrs. Blackmore and Langdon.

Iris Citronella.—The most beautiful of all the *Iris*s in the Show. It is of *squalens* type, the standards are golden and the golden falls are heavily lined with carmine, which contrasts well with the golden beard. Award of merit to Messrs. Wallace and Co.

Iris ochracea cœrulea.—A very delightful *Iris*. The standards are copper coloured and the falls have brown reticulations with a yellow base. The blade is bluish, shading to copper. Award of merit. This variety was raised by Mr. Denis of Ealarueles-Bains and shown by Mr. W. R. Dykes.

Lathyrus pubescens.—Although introduced from Chili in 1840, this beautiful blue perennial *Pea* is not at all common in gardens. It is generally considered to be a greenhouse climber and it received an award of merit in 1903. Some very floriferous sprays were shown by Sir William Lawrence.

Lupinus polyphyllus Six Hills Strain.—This new strain of *Lupinus* is all that can be desired in habit, form and colouring and in addition possesses that precious gift of fragrance and for this it

received the award. A very large exhibit was made. Award of merit to Mr. Clarence Elliott.

Mimulus luteus flore pleno.—This variety is so floriferous that the plants become a mass of glowing golden yellow colour. The flowers are of the hose-in-hose type. Award of merit to Messrs. B. Ladhams, Limited.

Odontonia Merope var. vivicans.—A large flower of *Miltonia*-like appearance and deep purplish mauve colouring. The circular lip is deep rosy mauve with a red mask and yellow crest. First class certificate to Messrs. Charlesworth and Co.

Papaver orientale Thora Perry.—One of the useful pigny *Oriental Poppies* bearing silvery

flowers enclosing a central mass of very dark crimson stamens. Award of merit to Mr. Amos Perry.

Potentilla fruticosa var. Farrerl.—A pretty little shrubby plant which bore large quantities of clear golden flowers. Award of merit to Mr. Amos Perry.

Pelargonium Pink Profusion.—A compact and floriferous "Ivy-leaved *Geranium*," which bears good trusses of very bright rose pink flowers. Shown by Messrs. F. Woolman and Sons.

Pyrethrum Eileen May Robinson.—A beautiful single variety of pale pink colouring, tinted light mauve. Award of merit to Mr. H. Robinson, Hinckley, Leicestershire.

THE SUMMER PRUNING OF FRUIT TREES

It is the bounden duty of a fruit grower to give full encouragement to his trees. Summer pruning or pinching is a direct aid to fruitfulness and it ought, therefore, to be regularly practised.

CULTURAL tasks in the fruit garden come forward with the seasons, and their successful accomplishment depends about equally upon the promptitude with which the work of the moment is put in hand and the soundness of the lines on which it is carried out. There is, perhaps, no detail of fruit management in which skilful growers differ so widely, as well in system as in the manner of procedure, as in summer pruning—or, as my best mentor in all fruit training, Mr. Morle, of Veitch's Southfields Nurseries of long ago, insisted on calling it, summer "pinching," although he used his knife with much more freedom than he did his fingers. And yet these masters of fruit culture do not drift from the primary objectives—the building up of perfect buds for the future and the assisting of the finish of the burden of the day—though, admittedly, they travel towards them by devious routes. But what, when all is said and done, does the particular road matter provided that the ultimate end is won?

The one outstanding, really substantial objection to summer pruning is the comparatively great amount of time that it demands. It is essentially a matter of judgment, backed by skill in manipulation, and it therefore devolves on the head-gardener personally or on the most trusted member or members of his staff. In this relation one might cross swords with gardeners under whom one has worked for their refusal to help the juniors, not simply by demonstrating the work to them, but by carefully explaining the whys and wherefores of the several details. If the chief does not feel disposed to teach all his staff he should, for the maintenance of the credit and status of his avocation, teach one or two thoroughly and encourage them to pass the knowledge on to others. This, however, is a digression.

The point is that summer pruning consumes a considerable amount of time which can be ill-spared from other and, perhaps, reputedly more important operations. This, presumably, is why it is almost wholly neglected where the staff is barely adequate to the demands made on it, and is a sound reason for total neglect where the strength is obviously unequal, as, unfortunately, is frequent, to cope with even the imperative work. If it were permissible to do in a private garden what is often done in a commercial plantation, namely, simply break over the summer shoots about the middle of August, good would be done undoubtedly; but the ragged, untidy appearance of the half-separated dying growths would be like so many heralds of the coming of the end of

the world—at least, as far as the gardener's tenure of his position was concerned.

It is impossible to state an inflexible rule as to when summer pruning must commence, since there will be variations with every year and garden and in lesser degree with every tree, but the season will always be covered by the period mid-June to mid-July, and the operation will finish during the first half of September, all subsequent cutting being relegated to winter pruning. There are cultivators who are prone to hasten the work forward, but in no circumstances should it commence until the leaves are perfect in size, no matter how freely the shoots may grow or how numerous they may be. That over-anxiety to start before the leaves are full-sized leads to an increase of labour, because lower buds than commence quickly and lead to crowds of young shoots which can never have substantial value; on the contrary, they are a nuisance. For equally sound reasons the start must not be postponed too long, because this spells long, vigorous growths which appropriate to themselves the sap at the same time as they shade fruits and spurs, and whose sudden, wholesale reduction will inevitably prejudice the health of the tree of the moment and the future prospects very seriously.

Speaking in the broadest sense, and taking no cognisance of the minor peculiarities of individual varieties, the summer pruner will have three types of growth always before him, apart from the leading shoots, which will be accorded a few words of special consideration. There will be, then, the stubby shoot carrying a bold, plump bud in a ruff of fine leaves; this is a spur, and the question of pruning or pinching does not arise in connexion with it. Then he will find the short shoot with six or eight leaves, conspicuous buds in the axils and a bold, plump bud as a terminal; again pruning or pinching does not arise in association with it. Finally there is the clean, healthy young shoot bearing about one dozen leaves, all of which are perfect in development, and this must be reduced to three leaves, exclusive of the two small ones at the extreme base. Following upon this there is every probability that two of the three reserved buds will break into growth, and when these have made about six perfect leaves they should in their turn be reduced to one leaf. From these will spring sub-laterals, each of which should be pinched to one leaf, as, in point of fact, must be all growths made subsequently.

Turning now to the leading shoots—extensions, as they may be termed correctly. There is a marked inclination on the part of inexperienced

growers to cut these hard back both at summer and winter pruning, under the supposition that this will check any tendency towards exuberance and lead, therefore, to superior crops. No such result will, or can, accrue. Excessive luxuriance must be suppressed by root pruning when the leaves are coming down in autumn, or by ringing, both in intimate association with scrupulously careful winter pruning.

Leading or extension shoots on bush and pyramid trees must be permitted to proceed to a length of at least 12 ins., when they should be stopped. Immediate swelling of the lower buds will follow,

and shoots which spring from the uppermost buds ought to have their points removed when three perfect leaves have developed, but not sooner; any subsequent growths should be pinched to one leaf, as made. The same principle of procedure in regard to extensions should be applied to side shoots on trees trained on restricted lines, except in the case of those trained in horizontal form. Herein it is highly important that each leading growth shall be trained in to its full length until such time as the available space is furnished, after which the suggestions set forth above will apply with equal force here. W. H. L.

CAMPANULAS ON THE GALIBIER IN JULY

THE Galibier Pass is a good place to visit in June, when the meadows are full of Poets Narcissus and sumptuous Anemone alpina. In fact that is, for several reasons, the pleasantest time to visit it. Yet to me it will always remain the place of all others at which to see *Campanula pusilla* and *C. linifolia*, and to find these at their best you must go in July. Neither species is rare. In fact, both are extremely common; but both are of absolutely first-class importance in the

almost impossible to define the difference. For many years now I have grown, as type *linifolia*, a very beautiful specimen which I picked out at Mt. Cenis. It is a sturdy grower, 6 ins. high, with very large bells of a gloriously rich glossy purple. At the same time I collected a charming pallida variety, with shining silvery lavender blue flowers. Also there is a white form.

At Lautaret in July, 1921, we potted around doing a lot of rather dull conscientious collecting until almost the end of our time. Often we

A CHARACTERISTIC AND CHARMING FORM OF *CAMPANULA PUSILLA*, THE VARIETY MISS WILLMOTT.

garden, so easy to grow, so exquisitely lovely, so profuse in flowering. Both, too, are variable plants. *C. pusilla* has given us besides several pallida forms and the delicious little alba, two such great plants as Miss Willmott and Miranda, which reminds me, by the bye, that *pusilla* should not be called *pusilla*, but *bellardi*, though it seems very doubtful if we shall ever abandon *pusilla*. It is now some years ago that *C. pusilla* Miss Willmott set Holland House on fire. Miranda is a later find, of Farrer's, and one of the best things he ever brought from the Alps, though hitherto it has not caused the conflagration one might have expected. *C. pusilla* is widely distributed in the Alps as a common roadside plant. It haunts broken shaley ground, never occurring in meadow turf. Occasionally it will turn saxatile, finding its way into a running crevice in some big rock, from which it hangs its bells so closely packed as to suggest a vein of some coloured ore in the rock. *C. linifolia*, too, is happiest in broken ground, though, unlike *pusilla*, it will sometimes venture into the grass. *Linifolia* is very near our own native Harebell (*C. rotundifolia*). One can never mistake one for the other, though it is

looked across the valley which runs down to Briançon, from which branches back and up the great Galibier Pass. One can see the road mapped out on the mountain sides, snaking and looping away and away up in gigantic coils, and we felt we must in the end face that long, high, tedious road-crawl, though we kept putting it off to the last. In the end we chose a Sunday to escape the dust and crowds which Sunday *chars-à-bancs* always bring to Lautaret. The lower reaches of the tramp were, from the flower point of view, dullish. The meadows, through which we made short cuts, were now hayfields, either cut or ripe for cutting. In June the year before they had been lawns of Gentian and Soldanella and all the other small early brethren. But now it was good to find and to smell the purple Martagon Lily. By midday we were half way up the pass, and there on a rocky roadside promontory we sat and discussed our nosebags and watched through glasses the arrival of minute *chars-à-bancs* at the hotel away down below. We watched, too, the awful descent by a *char-à-bancs* of our own Galibier road. It lurched and lumbered and swung adown and around most frightful hairpin

corners. There seemed no reason why it should not lurch over the edge, yet it never did. And it seems they seldom do, these Alpine *chars-à-bancs*. I enquired of a native about it. One did roll over, I was told, the year before, making seven pirouettes down a scree, shedding a passenger at each pirouette, yet none were killed! Then we visited a big scree up behind our feeding perch to get *Anemone baldensis*. It is an attractive plant in a quiet sort of way as it rambles through the stone slides with its parsley-like leaves and pallid star flowers. But it seems never to have taken a very firm hold on English gardeners or their gardens. On this same scree was *Campanula Allionii* looking as though a child had pulled all the blossoms of a Canterbury Bell and flung them on the ground. This, too, likes to ramble in scree. An astonishing plant with its splendid colonies of giant bells sitting practically stemless on the ground. It is the earliest *Campanula* to flower at home, and is quite easy to manage in moraine or even in ordinary light loam. A splendid plant, too, for a pan in the alpine house, and one which never fails to astonish.

Then we set ourselves to toil up the last half of the pass, and here the *Campanulas* began, *pusilla* and *linifolia*, and the higher we got the more wonderful they became. It was slow work, for the two species varied so widely and enchantingly that one had to examine every colony and every drift on the look-out for distinct forms. They grew everywhere, on the banks and all over the screes, filling whole gullies, above the road, below the road, and even in the roadside gutters. Some of the most astonishing *linifolias* were dwarf-stemmed forms with enormous bells of deepest glossy purple, and there were fat bells, narrow bells and trumpet bells of that curious form which *Narcissus triandrus* imparts to the trumpets of its offspring. The most enchanting of the *pusillas* was a wee dwarf, very low growing and compact, with minute round bells drawn in at the mouth like a Japanese lantern. And yet I don't know; there was a luminous pale blue beauty in great colony on an almost inaccessible slope above a waterfall. As it grew there it promised to make Miss Willmott (the *Campanula*) look positively dowdy and Miranda a washed-out fat bag of a thing. The sad thing is that two minutes after you have collected these *pusillas* they lose all their brilliance and charm. They look dull and draggled, and as you look at them you wonder why on earth you collected them. However, each as it was collected was wrapped separately and labelled "Big bell," "Baby bell" and so forth, and all are now supremely contented and happy and satisfied in numbered pots. Just near the top of the pass is a house which looks as though it ought to provide coffee. It is a great Jure. It helps one up the last wild flourishes of road, and there on a clothes line are road-menders' socks and a notice that refreshments are *not* provided. Almost we hated the last highest splendour of the *linifolias*, which here predominated and were more abundant and brilliant and bewilderingly varied in form than ever. At the top of the pass the road plunges through a long, dark, dripping tunnel, and from its gloom one bursts at the far end upon a marvellous view of sunshine and mountain far, far across to Mt. Blanc. Upon screes to the right of the descending road we found *Ranunculus glacialis* and *Geum reptans* abundant. After browsing here we sat in the sun and watched a motor cyclist tuff-tuffing away down the looped ribbon of a road miles down the pass till even through the glasses he was a speck which finally disappeared, apparently over a precipice, and probably round a corner. And so home to our Lautaret Hotel.

Stevenage.

CLARENCE ELLIOTT.

CORRESPONDENCE

COLUMBINES.

I AM a strong believer in sowing seed of alpine and other wild plants as early as possible in the autumn. In the case of hard coated seed I adopt occasionally the plan of sowing in stratified pots, *i.e.*, between layers of sand. That it can be overdone I have proved several times to my disadvantage in the case of Columbines. Fresh seed of *Aquilegia alpina*, obtained from Lautaret and sown on November 20, 1920, did not germinate until end of May, 1922. Perfectly sound seed of *A. flabellata* failed to germinate when sown in sand. Thus I have come reluctantly to the conclusion that it may be a distinct disadvantage to sow Columbine seed before spring.

I was under the impression that *A. alpina* is a perennial plant and it has certainly proved so in my garden. As a rule flowers of this species in gardens do not compare favourably with those of the mountains. One exception is a specimen in my alpine meadow, which was a picture of perfect loveliness and lasted a week longer than others planted in earth containing plenty of chips. To obviate disturbance of the root, transplant into small "Long Toms" when in the cotyledon stage.

This mixture in a hot Surrey garden is not to the liking of *A. iucunda* (*glandulosa*), which lingers on for years without ever flowering. The same applies to *A. calcarata*, only it vanishes more quickly. *A. flabellata*, waxing too fat on a diet which seemed none too rich, disappeared in winter 1920-21, and I believe this species does not love too much sun. *A. Stuarti* must now be considered a chimera and is no longer in cultivation.

The writer of the article on Columbines (page 262) did not draw attention to *A. pyrenaica* and its local varieties, all, as a rule, good and desirable garden plants.

Before closing I must mention another little known and beautiful specimen, *A. olympica*, blue and white, a strapping plant nearly 2ft. high and a fine deer. From my notebook I remark that my plants were raised in 1912. It comes nearly always true from seed and I shall be pleased to exchange a few packets of seed, when ripe, with your readers against seed of *A. calcarata* and *A. viridiflora*. I have been unable to obtain the latter true from dealers in seed. By the way, do you or your readers know of a Monograph on Columbines?—P. R. CURTWINO, *East Molesey*.

The Editor knows of no such monograph. Will any reader who does give us the benefit of his knowledge. Ed.]

THE GREEN COLUMBINE.

I WOULD that some reader could tell me where I might procure seed of the unusual *Aquilegia viridiflora*. It is well worth a place among the choicest plants in border or rock garden, although it always seems to be trying to escape notice by reason of the curious sage green colour of its flowers. I have seen it, and very beautiful it is, both in form and colour: a strong-growing plant, native (I believe) of Siberia, but who has it or where seed can be procured, alas! I do not know.—H. W. CANNING-WRIGHT.

A GRAFT-HYBRID.

I AM enclosing two sprays of bloom cut from my freak *Laburnum*. Every spring, in addition to the ordinary yellow blossom, there are sprays of different colours and apparently of different habit. Perhaps one of your readers could explain this. DUNCAN BARR.

The sprays sent (and illustrated herewith) were of *Laburnum Adami*, a graft-hybrid produced

accidentally as long ago as 1825, between the common *Laburnum* (*L. vulgare*) and the Purple Broom (*Cytisus purpureus*), which is commonly grafted upon the *Laburnum*. This tree always shows a tendency to produce specimens of the growth

TWO SPRAYS OF *CYTISUS ADAMI*,

Showing ordinary yellow *Laburnum* blossoms on left; purplish blossoms and characteristic growth of *Cytisus purpureus* at the top right hand and intermediate flowers and foliage in the centre.

and flower of both parents in addition to the intermediate cream-pink form.—Ed.]

THE ROTATION OF CROPS.

THE letters (pages 193 and 220) on this well-worn subject adhere more or less rigidly to orthodox lines which imply that rotations in the vegetable garden are desirable and even hint at their necessity. The most popular arguments in favour of rotational planting are that crops are superior in appearance, flavour and bulk; that they enjoy a comparatively greater immunity from insect and fungus enemies, and that they spell economy in manuring. On page 220 "J. F." urges, further, as a substantial merit that "the sowing or planting of a deep-rooting crop after a shallow rooting one enables the plants to feed at different levels in the soil, and to draw nourishment from the upper and lower spits in different years." I must join clear issue with this correspondent. The first part of his argument puts a premium on shallow cultivation, which is wrong for all soils, light, medium or heavy; and the second part ignores the natural law of moisture rising in the soil, this moisture carrying the elements of plant nutrition in suspension. Neither "J. F." nor any other cultivator can afford to rely on shallow soil culture any more than either can doubt that if moisture did not rise in the earth, crops would not flourish. I long ago convinced myself that rotation is in no sense necessary in the vegetable garden, and I have been successful in converting others to my view. The secret of success—the honest attainable in appearance, quality of flavour, human food value and bulk—in vegetable culture no more lies in the worshipped rotations than it does in the manure heap. Success lies in deep, mechanical culture carried out in the most thorough manner at the correct season, in the provision of a firm

bed for seeds and seedlings, in avoidance of the water pot until the very hour of compulsion, and in incessant surface working, though not always with the over-glorified Dutch hoe. It is, of course, imperative that there shall be periodical additions to the soil of a material which will maintain the humic content, and man's vision is drawn by the force of inherited habit to the heap of stable or farmyard manure, or, but in much lesser degree, to the incorporation of green crops. For myself, I would rather have, and should have if I could afford it, half a ton of Wakeley's hop manure or Rito than 20 tons of most of the impoverished stuff which is dignified by the description of "farmyard manure." If I lost a little in food it could easily be given to the growing crop in the form of one of the several excellent compounds advertised weekly in *THE GARDEN*, and if I thought that a stimulant was required there is nitrate of potash, or, and even better on occasion, a mixture of equal parts of that and phosphate of potash, and sulphate of ammonia waiting and unflinching. As for insect and fungus enemies my experience is that they come, rotation or no rotation, and the sensible man keeps himself in readiness to attack them with promptitude and vigour.—W. H. LODGE.

BEGONIA MITE OR RUST.

THIS pest has for many years caused widespread damage among indoor plants, its attacks not being, as the name might imply, confined to Begonias alone. Other plants that are commonly attacked are Bouvardias, Gloxinias, Streptocarpuses, Achimenes, Cyclamens, Celosias, Solanums and *Lucentia gratissima*, while all Gesneraceous plants are subject to attack. The name "rust" is understandably applied to the rusty appearance of the injured parts. The damage is usually confined to the growing points of the shoots, although in bad cases the injury may extend to the underside of the older leaves and even to the stem of the plant. Even now many cultivators do not associate an insect with the injury, which is perhaps not surprising, since for long enough it eluded the entomologist. When specimens of injured plants were received by post there were never any mites present on them, as they seem always to leave the specimen, so that the packing material must be examined if they are to be found. At present this mite is generally known as *Tarsonemus floricola*, Cau. and Fau., but it seems that its identity and life history have never been properly worked out. For many years the entomologist—or plant doctor—failed to find an effective remedy for this pest. Spraying with nicotine compounds, weak solutions of carbolic acid, soft soap and flowers of sulphur, proved more or less effective, but often caused serious damage unless great care was taken. Such was the state of affairs until a few years ago, when a private gardener discovered that the use of Campbell's Sulphur Vaporiser proved a cure for it, and what is of prime importance is the fact that it is an absolute preventive, some three or four applications in the course of the season being sufficient to keep plants free from this pest. The apparatus is quite safe if the instructions issued with it are carefully followed, and it is well known to Grape growers, who use it for mildew and red spider. In the latter connexion it is interesting to note that the Begonia mite is said to be nearly related to the red spiders.—J. C.

A TOO-SELDOM SEEN RHODODENDRON.

RHODODENDRON *IVERIANUM* or Ivery's Scarlet—the most brilliant variety mentioned in a recent issue of *THE GARDEN*—was raised many years ago by a man named Ivery, who carried on the business of a nurseryman in Dorking. The

land he cultivated has long since been built over, but I believe some of his descendants still live in that town. Some of the largest plants of this variety are growing in gardens around about Dorking, and a bush in these gardens about 12ft. in height and the same in diameter, was this year at its best in the middle of May. It carried thousands of trusses of flowers and was a gorgeous sight. Although raised so many years ago it is still comparatively rare. Probably because it does not flower freely in a young state, but after the plants reach the age of eight to ten years they will flower freely enough. Plants in full sunshine flower more freely than those growing in shade, and the colour does not burn, so one need not fear to plant this variety in full sunshine, but it must have shelter from wind. The habit of the plant is good; it does not get leggy, and the long, narrow, acutely pointed dark green leaves are a splendid foil to the brilliant scarlet flowers. The stamens are white, which serve to intensify the colour. The trusses are compact and of good size, and altogether this hybrid is undoubtedly the very best of its colour, flowering from late April through the whole month of May. There are two unusual features about this *Rhododendron*—namely, that it is freely visited by honey bees; that it is only on a very few flowers that seeds are produced.—S. W. PHILPOTT, *Anstie Grange Gardens, Holmwood.*

NATURE'S WALL GARDEN.

THE picture showing nature's planting of a dry wall, taken in the Island of Sark, is, I think most readers of THE GARDEN will agree, quite as effective as, though perhaps less brilliant in colouring than, man's efforts in this direction. *Sedum*, Pennywort (*Cotyledon Umbilicus*) and Lichen each do their part to give tone and beauty to the wall, without in any way obscuring the

A DRY WALL OF NATURE'S CLOTHING.

texture and natural beauty of the stone, a point too often overlooked by planters.—G. HARVEY.

BABY TULIPS—A POSER ?

I DO not know how many visitors noticed the vases of "baby" Tulips in the front row of the exhibit of the Anglesey Bulb Growers at Chelsea. The one that attracted me most of all was *Millet*, but there must have been at least half a dozen more. Mr. Watts, who was in charge, told me that when he had had a big "Tulip At Home" the previous week, his wife had decorated all the tea-table with these "babies" and that their visitors had gone mad about them. I know it would be so. My own housekeeper, who arranges flowers beautifully, is always asking me

if we could not grow some of these. She thinks there is nothing like them. In most years, however, we only get an odd dozen or two in many hundreds; hence her wish for more. This year they are much more plentiful; in fact, in our bed of about five hundred early *Tulip La Tendre*, practically every bulb put up a second "baby" flower. I suppose this must be one result of last year's baking summer. The question then arises, can the same productiveness be brought about by artificial means? I do not remember to have noticed anything of the kind having taken place on the occasions when I have put the bulbs in heat for the purpose of retarding their blooming in the following spring; nor can I say now if a similar thing occurred after that black year in *Daffodil* history, 1911, when we had quite as warm a summer as the last one. Can any of our English or Dutch growers throw any light upon the subject?—JOSEPH JACOB.

KEW GARDENS ON WHIT MONDAY.

"ONE is nearer God's heart in a garden than anywhere else on earth." Personally, I did not think so when I visited Kew Gardens on Whit Monday. On the Saturday before, the Gardens were delightful, but on the Monday it was as though Kew had been transferred from Paradise to Bedlam. There were, so I am officially informed, 54,005 people in the Gardens on that Monday and I should think that every person (except myself), took in 3lb. of oranges and three or four bananas, to say nothing of paper parcels, and largely spent their time scattering peel, skin and paper about.

Never before have I seen the Gardens in such a disgraceful condition, in fact, I believe it rivalled Hampstead Heath. The Gardens are intended primarily for those really interested in horticulture

GARDENING OF THE WEEK

FOR SOUTHERN GARDENS.

The Kitchen Garden.

Planting Brassicas.—Take advantage of all dull or showery days to get as many of the various Brassicas planted as will be required to meet the demands. Remember to allow of a good margin, if possible, to meet depletions by unfavourable conditions or from any other cause. See that Broccoli and other plants which have the winter to stand make their growth on firm ground. One good watering at time of planting and the latter firmly done, is generally sufficient to give a start to the majority of the Brassica family, but Cauliflowers should be frequently watered copiously during hot spells.

Cucumbers in vigorous growth and fruiting in houses or pits must receive regular attention in stopping and regulating the growths and the removal of exhausted foliage. Keep the roots in a healthy active condition by occasional top dressings of spent mushroom dung and good loam, and render the plants further assistance when cropping well by giving them thorough soakings weekly of diluted farmyard manure water, and by an occasional dusting over the whole bed with a good fertiliser, watering the same well in when applied.

Leeks.—As soon as convenient after this date the main batch of Leeks should be got out, choosing a well manured piece of ground, for the plants delight in liberal treatment. A suitable method to follow when dealing with a quantity of plants is to draw out deep drills 15ins. apart and then with a good dibber or bar make deep holes about a foot apart into which the young plants should be carefully dropped and each hole filled up with water to give the plants a start. Little, if any, soil is necessary in the holes at planting time. Where an early planting of Leeks was made to provide large specimens, the plants should be well supplied with water when necessary and occasionally thoroughly soaked with weak manure water.

The Flower Garden.

Climbers are all in vigorous growth and must receive periodical attention as regards tying and regulating of the growths before they become hopelessly entangled among other plants near at hand. A certain looseness of tying and training should be followed as much as possible where such does not interfere with the display of other plants. In dealing with Clematis though, particularly, a few strong shoots over other plants or their supports may often be made an interesting feature. Among Roses on walls, pergolas, etc., Clematises always add to the good effect, so long as a little discretion is used as regards colour combination and they may often be associated to advantage with plants which give a very early display and are somewhat dull afterwards, also among plants which are grown for an end of season display or for foliage effect, such as *Vitis*.

Violas are not so largely grown in Southern as in Northern gardens, and it is, I think, because of the amount of attention required, particularly during hot seasons, such as last, when it was almost impossible to keep any life in the plants. All spent blooms should be regularly removed and the plants mulched with leaf soil and spent manure if they are expected to last in good condition very long on dry soils. To provide an early display of blooms old plants are the best and enough should be lifted and divided and afterwards placed in lines in cool ground in the reserve plot and then placed in permanent positions in the autumn.

The Hardy Fruit Garden.

Thinning Fruit.—No hard or fast rules need be adopted in dealing with this work as so much depends upon the health and vigour of the trees and upon other conditions, such as the aim of the grower respecting size of fruits desired, and upon the amount of attention it may be possible to give to the trees in constant waterings, cleanings etc., thus rendering it possible in some cases to carry a crop much heavier than in others. One essential point to bear in mind is that when the health of a tree is not satisfactory, and where, owing to staff depletions the necessary amount of time is not available which should be spent upon the care of the trees, then overcropping must be carefully guarded against. Newly planted trees and very weakly ones should be cleared of their fruits in order to concentrate all energy upon the work of building up the trees for future crops.

research. Surely it is up to the public not to disfigure the gardens in this way, because such conduct may close the Gardens to them at holiday times. Next Bank Holiday I, for one, shall certainly stay at home.—HORRIS.

FORTHCOMING EVENTS.

June 21.—Southampton Horticultural Society's Rose Show, Hertford Horticultural Society's Meeting.

June 22.—Royal Botanic Society's Meeting.

June 24.—Windsor Rose Society's Show.

June 29.—National Rose Society's Summer Show, to be held at the Royal Botanic Gardens, Regent's Park, London.

Fruits Under Glass.

Figs.—The unfavourable climatic conditions experienced during early spring necessitated the use of considerable heat in the hot water pipes where early fruits were required. Where this was the case a keener look-out than ever must be kept for attacks of red spider or thrips, for each of these pests quickly become a nuisance when a sudden hot dry spell follows a cold spring, like it did this year during the month of May. The best antidote to such troubles is to give the tree thorough drenchings twice a day with the syringe. Even when Figs are ripening the syringing will not harm very much as the forwardest fruits may easily be removed first, and it is better to sacrifice an occasional fruit than have dirty trees, especially when there is a second crop to be thought of.

H. TURNER

(Gardener to the Duke of Northumberland).
Albury Park Gardens, Guildford.

FOR NORTHERN GARDENS.

The Kitchen Garden.

Cucumbers.—Red spider is a troublesome pest at this time, and unless checked by vigorous syringing of the plants and regular damping of the beds, the crop will to a great extent suffer. Dryness at the roots, and a hot, dry atmosphere, are the primary causes of red spider, so guard against this by affording liberal supplies of moisture and give occasional applications of liquid manure. Regulate the growth, removing all superfluous shoots and cut off the fruits immediately they attain a suitable size, standing the fruits stalk end in water if not immediately required. Frame cucumbers must also have their growths regulated, pegging down the leaders and top-dressing as required.

Savoys.—This popular Cabbage should now be planted in quantity for winter use. Plant the strong growing sorts in rows 2ft. apart and 20ins. between the plants in the row. The dwarf varieties, such as Little Pixie, may be grown much closer, 18ins. between the lines being ample, allowing 15ins. between the plants in the row. These dwarf kinds are highly esteemed for household use, being of convenient size and of excellent flavour.

Late Cabbage, such as Winningstadt, should also be planted now, and accorded a well enriched piece of ground, so that the best results may be obtained. For northern gardens, Winningstadt is probably the best keeping of all the late Cabbages.

Asparagus Kale.—For use during the spring months this popular Brassica should be planted by the middle of June, as it is essential that the plants are of good size before the winter sets in.

Peas.—A final sowing may yet be made, but it is advisable at this time to revert to an early variety. We find Gradus the most suitable of the earlier for this purpose and a good sowing at this date ensures excellent pickings on until the frost comes.

French Beans.—Further quantities of these should be sown now for succession, as it is always desirable to be able to procure fresh pods of this delectable vegetable as far into autumn as possible. For general cropping Sutton's Evergreen can be commended. This sort keeps in usable condition for a lengthy period.

Leeks.—The principal planting of Leeks should now be made, choosing ground which has been heavily manured, as this vegetable is a gross feeder. Draw deep drills and dibble the plants into fairly deep holes, dropping a very little soil over the roots. Liberal waterings should be given during dry weather and copious supplies of liquid farm-yard manure should be given as soon as the plants are established and growing freely.

Fruits Under Glass.

Vines.—It may be necessary at this time to subject the second viney to another thinning, for where the vines are in a vigorous condition the berries swell rapidly and generously show that no matter how judiciously the first thinning has been carried out, there are yet many berries that may be dispensed with. Added care must be taken so that none of the bunches may be damaged in the process. All sub-lateral growths must be kept in check up to the time the berries are stoning, when this work may be relaxed for a period. Examine the borders at intervals, and water thoroughly when required, so that the soil may be moist throughout.

Peaches in Pots should be assisted with generous waterings of well diluted liquid manure. Syringe

the trees in the evening so that clean healthy foliage may result.

The Hardy Fruit Garden.

Young Fruit Trees which were planted during the spring months will suffer readily should a lengthy spell of dry weather prevail, so water should be applied freely. Also mulch with well rotted manure. Should manure be scarce, the mowings from the lawn may be used and will prove an excellent check to evaporation.

The Flower Garden.

Rose Beds.—Hoe vigorously all beds and borders in the rose garden, keeping a sharp look-out for maggot, otherwise many of the flower buds may be destroyed. Attacks of aphids may be averted by timely spraying with quassia.

Aquilegias.—Seed of these elegant plants should be sown at this time in boxes in a cool frame, transplanting immediately the seedlings are of a suitable size. The varieties now procurable from a packet of seed are wonderful. The flowers are eminently suitable for decorative purposes.

JAMES McGRAN

(Gardener to Sir Henry H. Houldsworth, Bart.).
Coodham Kilmarnock.

GREENHOUSE AND CONSERVATORY

Rehmannia angulata is an excellent plant for the cool conservatory, remaining in flower as it does for a good many weeks. It is really a perennial and may be propagated each year from off-shoots, but the best results are obtained if it is raised from seed every year. Seed should be sown now, standing the seed pan in a cool house or frame. When large enough to handle the seedlings should be pricked off into pans or boxes, afterwards potting them up as they require it. By the autumn they should be in 5in. or 6in. pots, in which they may remain all the winter, growing them throughout in cold frames. Early in the New Year they should be transferred into their flowering pots, which are 8ins. or 9ins. in size if good specimens are desired. During all stages of their cultivation these plants do quite well in any good potting compost. Seedlings vary somewhat in colour, this seed should always be saved from selected plants.

Rehmannia kewensis is a hybrid between *R. Henryii* and *R. chinensis*, and is also worth growing for the cool greenhouse, and succeeds under the same cultural conditions as *R. angulata*.

Gilia coronopifolia is a beautiful biennial that is deserving of more general cultivation for the cool conservatory. It is easily raised from seed, which should be sown at this time in a cool greenhouse. When large enough to prick off the seedlings should be placed in pans containing light rich soil. They should afterwards be potted into thumbs, and again into sixty sized pots, in which size they should be wintered. This plant requires some care—especially in the immediate neighbourhood of London—to bring it safely through the winter months; for like many other Californian plants it is very impatient of stagnant moisture during the winter. I find it winters best on a shelf in a cool, airy greenhouse, during which time only enough water must be given to prevent the plant from shrivelling, taking care not to wet the foliage. Early in the New Year more water must be given, and as the plants commence to grow they may be potted into their flowering pots, which should be 6ins. in size. A free compost, good drainage and careful watering at all times is essential for the successful cultivation of this plant and well grown specimens should attain a height of 3ft. or 4ft.

Euphorbia pulcherrima (The Po'insettia).—Many cultivators make the mistake of propagating this plant too early. The middle of June is quite early enough for the first batches. This plant is easily propagated by pieces of the old stem cut into lengths of some 2ins. Some gardeners contend that such good results are not obtained by this method; personally I have not found any difference. In any case the usual procedure is to use young shoots about 3ins. in length as cuttings, leaving a shaving of the old wood at the base of the cuttings. As they bleed freely the base of the cuttings should be dipped in finely powdered charcoal, and should then be inserted singly in small pots and plunged in a warm propagating case, taking care that they are not allowed to flag. When rooted they should be potted up, and after they are established they should be removed

to an intermediate house for a few days, and then to a cold house or frame, where they should have plenty of air and full exposure to the sun, removing them to a warm house during September.

Chrysanthemums.—If these are not already in their flowering pots, no time should be lost in getting the potting completed. The potting compost should consist of good medium loam chopped up roughly, with the addition of a little leaf soil, or old mushroom-bed manure, and enough coarse sand or old lime rubble to render the whole porous. A forty-eight sized potful of fine bone meal should be added to every bushel of soil, about the same quantity of soot may also be added, but no artificial fertilisers should be used at this time. The plants should be firmly potted, and if large specimens of the decorative varieties are required, three plants should be put into 8in. or 12in. pots. Single plants should be placed into 8in. or 9in. pots. Instead of standing the plants out in their summer quarters at once, as is too generally done, it is better to stand them closely together for a few weeks, as moister and therefore better growing conditions can thus be maintained. It is also much easier to syringe the plants several times a day.

J. COUTTS,

Royal Botanic Gardens, Kew.

THE PROPAGATION OF THE SCOTCH ROCKET

(HESPERIS MATRONALIS ALBA PLENA.)

THIS, one of the very choicest of hardy plants, is too often lost in gardens simply for want of a little knowledge of its habits and requirements. For a couple of years or so the plants thrive and flower splendidly, but "all of a sudden" they mysteriously die off and the cultivator is left lamenting. It is, of course, only fair to say that it is not on every kind of soil this floral gem will thrive, for unfortunately it is somewhat fastidious in this respect, and no matter how skilful the cultivator may be, the plants simply refuse even to remain alive in some districts. It may be grown grandly on a heavy clay loam, but it probably prefers a fairly rich deep loam of a light character. Division of the root-stock is often advised, but long experience has demonstrated that by far the best results are obtained from cuttings in early autumn. Many readers who have tried this plant will pertinently enquire where cuttings are to be had, as usually the plants flower so profusely that not a single side shoot is produced without a flower-spike. It is here that a little foresight is demanded. Two or three good plants should be planted in the reserve garden, and as soon as flower-stems appear these should be cut back, which will conserve the strength of such plants and in due course induce the latent buds near the base to break forth into vigorous growth after the flowering season is over. These side shoots, if taken off with a "heel" and inserted firmly round the edges of 5in. pots filled with very sandy compost, will soon form roots. The cuttings will root if placed in a cold frame, but as damp is the great enemy during winter, it is preferable to stand the pots in a greenhouse from which frost is just excluded. The Rocket will not stand being coddled, so give abundance of air after roots are formed. In early March pot off singly into 4in. pots, using good but not over-rich soil. Keep in the greenhouse for ten days after potting, then remove to a cold frame, gradually harden off and plant out where they are to bloom by the first week in April. Treated thus few plants can surpass the true Scotch Rocket as a border plant.

The "VILLA" SPRAYER

PATENT NO. 161730. BRASS CYLINDER 17 IN. LONG X 7/8 DIAM.

"The Villa" Sprayer is now fitted with a new and greatly improved nozzle.
It is connected to the pump with the same sized screw as the old pattern, so that the old one may be unscrewed and replaced by that shown in the cut above.
Instead of the inlet valve being operated by a rubber band a BRASS BALL VALVE has been substituted.
There is nothing whatever to go wrong or to corrode. The liquid may be sucked up from the very bottom of the can.
By loosening and tightening the brass screw the spraying tube may be set to throw the spray at any desired angle, and it is more solidly constructed.
Former customers may be supplied with this new nozzle, post free, 1/6.
Ask your seedsman or ironmonger for the "Villa" Sprayer.

THE TALL BEARDED IRISES

THERE is probably no genus of hardy plants which can equal the Irises for interest, beauty and that diversity of colouring which inspired their name. It is a most remarkable family and so widely distributed, alike in Nature and in cultivation, that it might well claim the whole world as its country."

The old type Germanicas, in which there are shades of white, blue, purple and violet, and which flower during May, must now be looked upon as out-dated garden plants. In the so-called Tall Bearded Irises there is far greater interest. They have a larger range of colour, are endless in variety, comprising innumerable shades and tones of colour in their sectional families of *amœna*, *neglecta*, *aphylla*, *squalens*, *variegata* and *pallida*. They make an appeal comparable with that of the Lily and the Orchid. Both in stature, foliage and habit many of the newer forms of Iris stand proudly beside the former, while for colouring, form, perfume and general beauty they may easily equal the latter.

It is generally accepted that the Tall Bearded Irises are the most showy and interesting section of the great Iris family. The tall, stately flower stems frequently rise to 3ft. and 4ft. with greyish glaucous foliage, which adds much to the effect of the branching flower scapes. Their delicately textured blossoms may be compared to the silken and velvet robes of queen or courtier.

Space would not permit me to dwell upon all I saw in the various collections at the recent Iris Show, containing as they did some of the finest possible types. I will, however, mention briefly just a few of those which appealed to me as among the finest, all certainly of first-rate merit.

Souvenir de Mme. Gaulichau, a tall and distinct deep royal purple, well built flower.

Bruno, a great beauty, where bronze and reddish purple pre- dominate.

Ambassadeur.—Standards, smoked reddish violet; falls, dark velvety red. Large, well balanced flowers.

Perry's White.—Standards and falls pure white. The largest and most stately I have yet seen; certainly the "Queen of Irises."

Lord of June, a perfect giant in Iris. Standards, lavender blue; falls, violet blue; the surrounding atmosphere completely permeated by its powerful and delightful perfume.

Robert Wallace, a real masterpiece in colour, being a rich ruby purple; well built flowers.

Marian Cran.—Standards, light rosy purple; falls, deep rose purple; white crest.

Lady Sackville, a most beautiful and well built flower; standards, broad and of a silvery shade of sky blue; falls, rich crimson purple; yellow beard.

Ma Mie, pure white, standards and falls beautifully frilled blue.

Neptune.—Standards, pale blue; falls, purple. Delightfully fragrant.

Isoline.—Standards, silvery rose, flushed bronze; falls, purplish old rose, golden throat, yellow beard.

Alcazar.—Standards, lavender blue; falls, deep purple, with a bronze veined throat, orange beard.

Black Prince.—Standards, purplish blue; falls, rich velvety purple, almost black; most distinct.

Iris King.—Standards, old gold; falls, rich bright velvety crimson maroon, margined gold.

Caprice.—Standards, reddish purple; falls, deeper, bright yellow beard.

Magnifica.—Standards, light violet blue; falls, long, deep reddish violet, reticulated brown at base; bold yellow beard; sweetly scented.

Ed. Michel.—Of very imposing appearance, tall, stately spikes, bearing distinct wine-red flowers.

Eldorado.—Standards, a curious combination of yellowish bronze shaded with heliotrope; falls, violet purple shaded bronze yellow, with clear gold beard.

Donna Nook.—Standards, lavender blue; falls, bright purple shaded lavender; large, well built flowers; tall, stately habit; highly perfumed.

Jacquésiana.—Standards, crimson copper; falls, rich maroon.

Lady Foster.—Stout branching spikes; standards, pale blue; falls, bluish violet, veined gold at base.

La Niège.—Standards and falls pure white; a good variety for front row of border.

Monsignor.—Standards, pale violet; falls, rich velvety purple, with paler edges.

Flammenschwert, a real acquisition, large well formed flowers; standards, rich yellow; falls, velvety crimson maroon.

Prosper Langer, larger than *Jacquésiana* and brighter in colour.

Queen Mary White, pure snow white, white beard.

Grevin.—Standards, violet, flushed and

TALL BEARDED IRISES IN A PERGOLA.

shaded yellow; falls, dark violet; large, well built flowers.

Nibelungen.—Standards, fawn, shot bronze; falls, violet purple, suffused bronze.

Princess Victoria Louise.—Standards, primrose yellow; falls, reddish purple, distinctly margined primrose; very effective.

Caterina.—Tall, stately spikes, bearing massive lavender blue flowers; falls, prettily veined at throat; sweetly scented.

Cherubin.—Wonderfully free; standards, white, flushed pink; falls, pale lilac.

Oriflamme.—Exceedingly large, well built flowers, sweetly scented; standards, bright blue; falls, dark purple.

Miss Dorothy Rowe.—Distinct branching habit, medium-sized flowers; standards, lavender blue; falls, deep reddish purple.

Rhein Nixe.—Standards, white; falls, rich violet purple, with conspicuous narrow white edge.

Mrs. Neubronner.—Standards and falls, deep golden yellow; flowers rather small.

Miss Eardley.—Standards, old gold; falls, crimson maroon, margined yellow.

Lohengrin.—A most beautiful *Cattleya*-rose shade; large, handsome flowers.

Minos.—Standards, light blue; falls, deep purple blue; free branching habit; sweet scented.

Mlle. Schwartz.—A tall, stately variety of French origin, bearing large, well built pale mauve flowers, much branched.

Pfauenauge.—Quite distinct; standards, olive gold; falls, curiously shaded, gold at the edge and deepening to plum towards centre.

Dawn.—Standards, pretty sulphur yellow; falls, bronze, bronze at throat.

Few plants respond more kindly to well worked ordinary soil than the Bearded Irises. To attain full-sized flowers and vigorous foliage, deeply worked soil should be the rule, and if lime is absent, the addition of a little is desirable.

It is well to transplant every three or four years, and the best season for transplanting is, should the weather prove favourable, as soon as possible after flowering. It, however, this cannot be done they may be planted quite successfully during the autumn and spring, with the difference that the plants do not attain their full height, the quality of flowers will not be so fine, and that sometimes they will miss flowering for a season.

The Bearded Irises are unquestionably the flower of the garden, as, providing they are given a sunny position, they will thrive equally well in the herbaceous border, on banks or slopes. I have seen them growing quite close to the water's edge on banks at such a distance that their toes, or roots, do not touch the water; also on the out-kirts of shrubberies. WILLIAM LOGAN.

WHEN TO TRANSPLANT

THERE is a widespread controversy as to the best time to move the giant Bearded Irises. Such arguments mostly arise with plants which are exceedingly difficult or exceptionally easy to transplant. In this case it is the easiness with which, given ordinary care, these Irises may be moved and re-established which has provoked the controversy.

It is certain that these plants have been transplanted successfully at every season of the year,

not excepting the dead of winter, but with choice and perhaps expensive varieties in question it is certainly not advisable to remove them after root action has ceased for the season. Removal immediately after flowering is often advocated, and where the ground is ready for them, this season can hardly be bettered. All through July the nurserymen will be propagating for themselves and sending stocks to all parts of the country to Iris enthusiasts who have proved this time the best at which to establish them. In many gardens, however, it would only be possible to plant or divide Irises at this season by disturbing the effect of beds and borders which, with so easily moved a plant in question, is certainly not worth while.

Early in September, while the ground still retains some of the warmth bestowed on it by summer sunshine, is an excellent time to plant, but not, let it be whispered, too good a time to order new varieties, since those most wanted may by then be sold out unless the order was placed betimes. Much depends upon the season, but as long as the ground is moderately warm planting may well continue. It is, however, a mistake to plant in January, for instance, in the hope of getting better flowers than with later planting. The only result is likely to be the setting up of rot among the unavoidably damaged thong-like roots.

Irises planted in March usually flower well—the buds are already formed in the heart of the plant—but are usually wanting in size and stature the first season. As to their behaviour the following year, the experts disagree, but with ordinary care they should again flower well.

THE MAGNIFICENT NEW IRIS BRUNO, A STUDY IN BROWNS AND PURPLES. NOTE THE FINE FORM.

IRIS KING WITH I. VARIEGATA AS COLLECTED IN THE BALKANS, SHEWING IMPROVEMENT IN SIZE AND SUBSTANCE.

THE USES OF MATERIAL

III.—THE ARRANGEMENT OF BEARDED IRISES.

THE newest of all the glories of the garden! Not that the Iris is new to the garden, for it has a history of hundreds of years, but in an incredibly short period it has swept into a popularity unique in the whole story of floriculture. Twenty-five years ago the Iris was a valued garden plant, no more, no less. To-day it has entered the ranks of the elect few, such as the Rose, Lily and Carnation. The evidence of this is not far to seek: The Iris Conference in Paris; a special Iris Meeting under the auspices of the Royal Horticultural Society at Vincent Square; special visits by the keenest and best informed men in America to both. Twenty-five years ago this was beyond our wildest dreams. Now the thoughts of the leading lights in the horticultural world have been for several weeks concentrated on the Iris.

There is no need to ask why this is so. "Beauty is the quality that makes to endure," and of all the flowers that to-day give to the garden-lover joy none is more fair in form, exquisite in colour variation, or subtle in appeal to the sense of beauty than are the wonderful Irises of June.

Many years ago I remember an old, old man who used to tell me all sorts of wonderful things about flowers that will never be found in books. He was not a learned man, but he had a faith all his own, or perhaps he invented one for my benefit. It was certainly a very beautiful faith. He said that the souls of mortals came to earth through the medium of flowers. The colours of the flower were indicative of the character of the individual whose body the soul would ultimately inhabit. There were no truly black flowers, because there were no characters entirely and altogether bad. There were few really pure whites, because they only inhabited the infants who died before they were conscious of good or evil. Some, like Tigrisias, were just those splendid stars that burst brilliantly on our social system for a short time and then disappeared. Red flowers were soldiers; blue, philosophers and scientists; rose and pink, poets and artists; yellow, misers and self-seekers generally; and so on. I am afraid I must have absorbed more of his teaching than was beneficial, for I must confess that I never walk among the Irises without unconsciously applying it. For this reason I am perhaps inclined to extravagance of language with regard to them. Moreover, there is evidently something in the flower that appeals to the romantic side of all who have dealings with them. The nomenclature of the many varieties is evidence of this. Look through a list of varieties and you will find that about 90 per cent. of the names are suggestive, commemorative or descriptive. One raiser goes to the pages of Shakespeare, and fits his flower with both name and character at the same time. Another sees his garden peopled with the romance and chivalry of Camelot and finds in Tennyson's "Idylls of the King" knights valiant and ladies fair who are to him so real that his choicest productions are found worthy to bear their names. Another finds his names in the departed glories of an Eastern Empire, while yet another sees in the pure depths of colour a "Blue Lagoon," or in dainty poise and spreading falls a "Blue Bird." Indeed, the Irises are more happy in their names than perhaps any other flower of similar popularity, which is due to the fact that no other flower offers quite the same romantic sublimity of beauty. Perhaps some

etymological purist will object to the use of the word "romantic" here; then I shall retort that one great writer has said: "The real and proper use of the word romantic is simply to characterise

"LACY" AND BEAUTIFUL, THE TALL FREE-FLOWERING IRIS DIMITY.

an improbable or unaccustomed degree of beauty, sublimity or virtue."

It is perhaps this very fascinating power over the senses that has detracted my thoughts thus far from the object with which I set out, namely, to write rather of the uses of Irises in the garden than of what they are. First, then, they are the finest of border plants, and this for several reasons. Long before their flowers appear their sword-like leaves furnish the herbaceous border with green and grey relief. The young growth acts as agreeable furnishing among the later spring flowers. When the time comes for them to open their flowers there is a colour range that will offer harmony or contrast to every other flower in season. If it is cool greyish lavender colour you want there are the Pallida forms, some very tall, such as Pallida dalmatica, others smaller in stature, but equally delightful as to colour; or if you require something very stately and imposing, free flowering beyond regret and of the most exquisite shade of soft rose-lavender, there is Sweet Lavender. Another giant of equally

soft colouring is Ann Page, perhaps the finest of its type, with everything that grace of form and delicacy of colour can add to magnificence of stature to recommend it. Others that come within the same colour group, of varying height and with many subtle distinctions of colour variation and form, are Drake, Mlle. Schwartz (too pale to be called blue, too blue to be called grey, but a gem in every way), Morwell, Ballerine, Goldcrest, Viola and others. Grouped with pink Lupins, surrounded by pink Heucheras, or growing in association with masses of the paler pink shades of Pyrethrums, they one and all delight the senses with that harmony of colour arrangement that gives to colour in the flower garden all its realised attraction. But a change will be desired, and it can be found in the warmer colouring of Iris King with its old gold standards and deep reddish maroon falls, or Marsh Marigold, a pale yellow and warm brown combination, Dusky Maid, Nibelungen, Maori King, Knysna and many others of which yellow forms an important item in the colour scheme. Most of these are sufficient in themselves so far as the colour in the border is concerned, but they associate well with the deep purple Lupins, near the bronze-green foliage of certain Pæonies, or with any foliage similar to that of Prunus Pissardi.

It is impossible to take all the various colour groups and deal with them separately, and it must suffice if I point out that the colour range is as rich and perfect as it can be. Pure white, white with delicately pencilled markings or varying suffusions, purples of deepest dye, violets rich and full, yellows that are all yellow, and yellows staining and suffusing every other colour, and a whole host of indefinite graduated colours that can neither be accurately named nor described, each of which will find its place in the well designed herbaceous border.

Another use for the June Irises is to mass them in bold groups in the open spaces in front of the shrubbery borders. Flowering and foliage shrubs play a much more important part in the garden proper than they once did. There is an infinite variety at our command to-day, and the shrubbery border is not the dull affair it was once. Even so, as the later spring-flowering shrubs are passing their best the Irises are invaluable in prolonging the colour effects until summer has asserted itself and such borders take on new attractions.

Nevertheless, it must not be assumed that I am advocating using Irises merely as temporary furnishing for existing shrubberies. Rather would I suggest that they are worthy of creating such associations for their own value; in fact, the garden can provide no more beautiful combination than groups of Irises backed by the sombre tints of the dark-leaved Japanese Maples. If the position is too exposed for these beautiful foliaged shrubs there are the Prunus Pissardi, Blietana and Moseri, Corylus Avellana purpurea (the purple-leaved Nut) and many others that will produce equally enchanting effects.

One of the most brilliant effects that can be produced is by associating Azaleas, preferably the later-flowering varieties, with some of the colder toned Irises. Mixed they cannot, or at least must not be. The soil requirements are quite different. Azaleas will not have lime; Irises, at least the June-flowering bearded section, require it. But there is one accommodating factor in the case, that whereas you can hardly extract lime from the soil that contains it, you

can apply it locally to such plants as require it. A broad open glade through woodland, a fringe of late-flowering Azaleas, interspersed here and there with dark foliaged shrubs, such as are mentioned above, and then, in broken groups, masses of Irises of the earlier June-flowering varieties, and you will produce a riot of colour that no other combination can provide. Moreover, this colour madness may be full of method. There need not be an inharmonious note in the whole, because though you may splash a sunset glow broadcast upon your garden area, crimson, gold and orange, you will find among the Irises a sufficiency of cool colouring to subdue where necessary, enhance where desirable, and unite the whole in one grand natural colour harmony.

There is yet another method of using these wonderful flowers, although it is not for everyone.

realises how far progress has wafted the Iris. Another exceptional variety, both as regards stature, size of flower, colour and form, is Asia. Pale lavender, red-purple, brown, gold and bright yellow mingle in this remarkable flower. Alcazar, another violet and purple giant, is a very noticeable variety. A wonderful impression of blue is conveyed by a group of another giant, Crusader. Of a distinctly different colour is Edouard Michel, nearly approaching red. This variety has an exquisite wave in the fall that gives it a very distinctive and attractive appearance. A group of varying lilac and rose shades claims attention. It consists of a perfect gradation of colour and includes Queen of May, M. Aymard, Miriam Troost, Lancelot, Lohengrin, Phyllis Bliss, Roseway and the ever-flowering Mrs. Alan Gray. But perhaps the most wonderful colour

AMONG THE JUNE IRISES

THE Bearded Iris, a sufficiently common but not over-valued flower in gardens for many generations, is fast coming into its own. The first seriously and systematically to attempt the improvement of these Irises was M. Philip de Vilmorin, and until recent years almost everything new of any note was marketed by Messrs. Vilmorin-Andrieux et Cie, whose productions are still to the fore. No one country can, however, now claim a decided superiority for the sorts of its raising. It is safe to say that some of the English-raised varieties are as good as any in commerce; and many fine varieties have been raised in the United States, notably by Miss Sturtevant. It is a little difficult to compare the merits of American and British varieties, since some of the best American sorts hardly do themselves justice here and some of the stateliest of "Britishers" fail in the trying climate of Eastern U.S.A.

The raising of new Bearded Irises is a work calling for rare judgment and much patience. It is, however, hardly recommendable as a money-making proposition. Use what judgment one may, one is hardly likely to find more than one per thousand seedlings which is worthy of further cultivation as representing either a distinct break or a noteworthy improvement in size, habit or colouring on some existing variety. Even then, it may well turn out eventually that some other raiser has effected the same improvement, and that his flower is nearer to perfection than one's own.

Raisers have, naturally, each their own idea as to the most important point in a new Iris, which point must, of course, be accompanied by considerable merits in other directions. The Iris is before everything a stately flower, and to the writer two points of outstanding importance are stature and clear, bright (garden) colouring. A visit, the week before the Iris Show, to Messrs. Perry's "plant farm" at Enfield showed that the brothers Perry have much the same ideals. Stature their seedlings certainly have, and some of them are sure to be heard more of in the near future. Most of these possess a great deal of pallid blood.

The closely held flower and narrow, upright spike characteristic of the plicata section and to a lesser extent of the pallidas have been largely bred out in present-day strains by the introduction of neglecta and trojana blood. Considering these Irises from the standpoint of flowers for garden adornment, this represents a dubious advance. The narrow spike is certainly dignified when seen massed above a strong clump of foliage, and there should be room for it, as well as for the candelabra-like inflorescence to which the word "spike" is hardly applicable.

Such varieties as Dominion, Ma Mie and the novelty, Bruno, attract by the perfection of their flowers in colouring and shape. As garden flowers they must give place to many sorts with individually less handsome blossoms.

So much intercrossing has been effected that it is difficult—it would perhaps be more truthful to say "impossible"—to allot most new varieties to any particular section, yet the old divisions have their value as enabling one to appreciate the habit of a plant referred to the particular section.

If these Irises are to continue to increase in popularity at the rate they have done of late years, an abundance of varieties must be raised—stately in habit—and clean and yet strong in colouring, such as will, in fact, make delightful

JUNE IRISES, CATMINT AND MAPLES.

It is in the devotion of some portion of the grounds exclusively, or almost so, to the cultivation of Irises. In such a case the earlier-flowered species and varieties would have to be introduced, and also the later-flowering, grassy-leaved varieties. Time and space forbid dealing with these now, and in any case it is the June picture with which we are concerned.

The picture that rises before my eyes is that of a long valley-like depression on the outer extremities of the garden. It is perhaps, soft, or goft, wide, and bending to its slight undulations a little rill gurgles its way along at the lowest level. Fringing this tiny stream are tufts of foliage, showing where some of the later-flowering, grassy-leaved and moisture-loving Irises have yet to flower, and also some, like the Sibiricas, past their best. Away up the sides of the valley, well removed from the stream and stretching to the highest crest and beyond, are breadths of wind-stirred colour, for it is June and the Iris has come to its own. Here is the giant Lord of June, a peer indeed among its fellows, and as it moves in the wind it becomes a blue and violet haze. Next, the eye is caught by an exquisitely shaped flower of delicate colouring—white, veined lavender—called Dmity. Then there is a wonder, all red and purple and bronze and orange, with which mingles a modicum of brown—Cretonne. Away in the distance is Camelot, very tall and stately, with creamy white flowers, edged with a delicate veining and thread-like margin of pale violet. Ma Mie, another variety of similar, though somewhat smaller, hues, is also attractive; and it is by comparing these two with the older Mme. Chereau that one

note in this wonderful garden is where all the gold, bronze, copper, brown and every warm metallic hue mingle—Nibelungen, Romany, Mithras, Eldorado, Ambassadeur, Opera, Prosper Langier, Jacquesiana, many of which in the sunlight appear to have the texture, as well as the colour, of the metals they resemble.

Elsewhere are stretches of white, or white with light markings and suffusions, deep red-purples, faint creams, pure yellows and every variation of violet and purple, but to name them all would be wearisome and futile.

These, then, are some of the uses to which Irises can be put. There are others, but space forbids dealing with them. Now for a warning as to the position in which they should never be grown. Formal beds, on terraces, or in positions where prolonged colour effects are desirable, are not the places for them. A garden of geometrical design, with walks between flower beds near the house, should never be devoted exclusively to Irises. If they are planted in such beds (and it may, of course, be the only place in which they can be grown) then they should form only about one-fifth of the plants used, the remaining four-fifths being plants that will make such gardens interesting during the period when Irises are not in flower. There are a hundred things that can be planted with Irises to flower at different periods. Where the garden is of sufficient extent to allow of devoting a portion to the purpose of their cultivation without destroying the interest in the garden as a whole, it is well worth doing; but there is no compensation for the sacrifice of the whole garden year even in the joys of the wonderful June Irises. GEORGE DUNSTON.

garden pictures. Beauty of finish, excellence of form and subtlety of colouring on close inspection are all very desirable additional qualities, but these are of secondary, not primary importance.

The pallida group needs little improvement as regards size of blossom or stature. A collected form, *Iris pallida dalmatica*, has a dignity of bearing and a grandeur still unattained by any variety attributed to the *squalens* or *variegata* sections or even to the *neglectas*. Progress here must be directed to improving the colour-range. Already the original silvery lavender has become in one direction a clear lilac-rose (Susan Bliss), in another bright wine purple (Edouard Michel), and in yet another the falls are deep violet purple (Alcazar); while within these limits there are such magnificent varieties as Lord of June and the silvery-blue Drake, surely one of the most effective Bearded Irises yet in commerce. The aim, however, is to produce a race of Irises with the stature of the pallidas and *plicatas* and the colourings peculiar to the *squalens* and *variegata* sections improved and made clearer. For this reason great importance attaches to such sorts as *Iris King*, illustrated on another page and compared with *Iris variegata* as collected in the Balkans, and that exquisite novelty, *Citronella*, in which this amalgamation of qualities has to a great extent been effected. The richly if somberly tinted *Sunset*, also illustrated, also marks a notable advance. It received a well deserved award of merit at the recent *Iris Show* under the clumsy name *I. ochracea corulea*. Very free flowering and an excellent grower, its good form the picture will attest. It is, we understand, to be distributed this autumn by Messrs. G. G. Whitelegg and Co.

There is still an immense amount of work to be done before all the existing colours in Bearded

Irises are adequately displayed in handsome flowers on tall stems, but there is every reason to hope that the colour range may be very considerably extended. True blue is a colour unknown in Irises, but the lovely *I. sibirica* Perry's Blue is many shades nearer to it than any Bearded Iris yet seen. There does not seem any reason either why the lilac-rose shades should not approach more nearly still to pink on the one hand or to red on the other. It will be seen therefore that immense as is the progress which has been achieved, there still is a wide field of endeavour left open.

On Friday, June 9, there were to be seen at Messrs. Wallace's Tunbridge Wells nursery some of the most important personalities in the Iris world, including M. Mottet (representing Messrs. Vilmorin-Andrieux), Mr. Bliss, Mr. Yeld, Sir Arthur Hort, Mr. Dykes, Mr. Wister (President of the American Iris Society), Messrs. E. H. and G. N. Bunyard and, of course, Mr. R. W. Wallace himself, all intent on comparing and appraising the newest varieties—some of them as yet unnamed—both with one another and with older sorts now recognised as standard.

M. Mottet admitted in a speech he made at the luncheon that he had not realised what strides had been made with these flowers in this country. If asked to give the five best varieties to date he should, he said, name Duke of Bedford, Swazii, Cardinal, Bruno and Dominion. Dominion he considered the largest, but he thought the best of the five Swazii, because, in addition to wonderful flowers, it has height.

Mr. Wister did not agree with M. Mottet as to the five best. It was, he said, very difficult to give a best five or even a best dozen, but he thought M. Mottet had been too generous to England. *Ambassadeur* should certainly be in

the first five. The best three in Mr. Wister's opinion are *Ambassadeur*, *Prospero* and *Swazii*. He leaves *Dominion* out because, so far, it has not flourished with him. The best five varieties under English cultivation would probably not be the best in America, owing to the different climatic conditions.

Mr. Bonnewitz, another Iris enthusiast from "over the water," had been more successful with *Dominion*, so that it should be a success in the central and particularly the north-western States of the Union. Mr. Bonnewitz hails from Ohio.

All the experts are unquestionably in a king size something of a petish, but this is assuredly a quality which may be overdone. *Lord of June*, for instance, errs, if at all, upon the side of over-largeness. It is doubtful if there is a more pleasing variety in commerce than the silvery-blue pallida form, *Corida*, which is only moderate in size, but is distinguished by admirable spacing of the very pleasing flowers. This variety was very notable among Messrs.

THE GLORIOUSLY FORMED IRIS DUKE OF BEDFORD.

Wallace's large collection. Speaking generally, masses of colour were for the most part made by flowers individually quite moderate in size.

The Bearded Iris achieved fame too late to be a florist's flower, so that raisers have no arbitrary standards of form to contend with. Beauty of shape and proportioning, for which substance is necessary in the standards, there should be; beyond that there is hardly any limit to the number of pleasing arrangements that may be evolved and welcomed. The strongly held falls of *Bruno* or *Dominion* certainly make a big appeal and, moreover, give an effect of size, but some of the varieties with drooping falls are very beautiful and modest-looking. A word of warning seems necessary here, however. Some of the very newest seedlings of this type have the falls very square sided and large, and it must be confessed that, however showy such varieties may be massed in the garden, their form is upon closest inspection the reverse of beautiful.

The use of lime to combat, and as a preventive of, rhizome-rot is now universal, but the known easiness of culture of these rhizomatous Irises often make planters neglectful of those details which make all the difference between complete success and comparative failure. A deeply worked but thoroughly consolidated soil should always be provided, well drained at all seasons. Burnt earth is always beneficial.

THE RE-CHRISTENED IRIS SUNSET.

THE ROTHERSIDE IRISES

CHARMING as are the Bearded Irises for garden decoration, they must give place as cut flowers to the bulbous Spanish, Dutch and English strains

flowering and exceptionally fine strain of the Spanish Iris (*I. Niphium*), introduced by Mr. C. G. Van Tubergen, junior, of Haarlem, to whose

THE "ROTHERSIDE" STRAIN OF BULBOUS IRISES.

and the related Algerian species *tingitana*. The Rotherside Bulbous Irises illustrated herewith were recently exhibited at Vincent Square by Messrs. Herbert Chapman, Limited, and were much admired.

The strain has been evolved with the idea of filling the gap which exists among bulbous flowers between the late-flowering *Narcissi* and the ever-welcome Spanish Irises, a gap already partially filled by the so-called Dutch Irises, really an early

work in several directions bulb lovers owe a debt of gratitude.

To return to our muttons however, by re-crossing these Dutch Irises with the older forms of Spanish Irises, on the one hand, and the early, but not very free Iris *tingitana* on the other, there has been evolved this strain of Rotherside *Niphium* Irises which mark another step forward and which should be invaluable not only for cut flower, but for culture in pots.

THE ROCK ROSES IN NORTH WALES

If not, generally speaking, entirely hardy, the Cistuses are too charming to be omitted from any but the bleakest gardens.

THE *Cistuses* comprise one of the most important groups of flowering plants with which our gardens are adorned, and though none of them is suitable for bleak climates, most can be grown to perfection where the winters are not too severe and the soil well drained. All are sun-worshippers, most persistent bloomers and so easily raised from cuttings (which come to a flowering size in a very short time) that in districts where the winters are sometimes keen enough to injure them, a stock can always be held in reserve. They probably all like lime, though this is not essential.

The most familiar and one of the hardiest is *C. cyprius*, and a well grown bush of this old kind, bearing legions of its large paper-white, poppy-like flowers with a deep maroon blotch at the base of each petal, is a cheerful and lovely object in the later days of spring. Though often called the Gum *Cistus*, this name rightly belongs

to *C. ladaniferus*, which bears a close resemblance to the above, but may be easily distinguished from it by the flowers. In *ladaniferus* these are borne singly at the leaf axils, whereas those of *cyprius* are produced in clusters. In colour, size (often 4ins. across) and form these flowers are much alike, but those of *ladaniferus* often have rather more red in the blotch and in many forms the leafage of the latter is much narrower than in *cyprius*. There is a fine variety of *C. ladaniferus* known as *immaculatus*, whose flowers have no blotch, these being pure white and usually larger than in the type. All of these will make large bushes up to 6ft. high, but in some places they may attain twice that stature with a stem 4ins. to 6ins. in diameter. The leaves are covered at most seasons with a gummy secretion which is pleasantly aromatic.

Though some discerning nurserymen list them both, I can see no difference between *C. lusitanicus* and *C. Loreti*. This is a delightful little shrub,

smaller, semi-prostrate and more compact than the foregoing, and whose white flowers, which often remain on the bush until late afternoon, may be recognised by their bright crimson blotch. The leaves are slightly viscous, and this variety is in our experience rather more susceptible to frost than any previously mentioned. Albeit, *C. lusitanicus* is such a charming kind that it is well worth a trial anywhere. It is said to be a *ladaniferus* × *mons-peliensis* hybrid.

We now come to the much bigger, coarser and more robust *C. laurifolius*, which is hardiest of all. This species makes a wide, spreading shrub up to 8ft. or more in height; the leaves are a greyish green, and the pure white flowers, with a suggestion of yellow at the base, are lavishly produced in bold clusters. A fine plant for an open spot in the woodland or shrubbery and one that is more easily raised from seed than cuttings. Another good woodland *Cistus*—for it is one of the very few which will do with but little sun—is *C. obtusifolius*. This makes a shapely little shrub of dark green, glossy leaves, which in early summer are almost hidden by the yellow-centred, white flowers, these being about 2ins. across. *C. obtusifolius* is one of the easiest, and in habit and appearance comes near to *C. corbariensis*, which has slightly smaller flowers of the same type, borne in terminal clusters and preceded by reddish tinted buds.

C. salvifolius is another white-flowered species that runs close to the last mentioned. Plants sent out under this name are apt to vary considerably in form, some having the true Sage-green leaf, others more nearly approaching the foliage of *obtusifolius*. This variability, a characteristic common to the species in its native habitat on the Mediterranean, has led to a multiplication of varieties which is confusing. I have found *salvifolius* as hardy and easy as *obtusifolius* or *corbariensis*, which is to say that it can stand 15° to 20° of frost in dry soil, and it is a plant that will grow to about 3ft. and "carry on" for years, taking care of itself.

In *C. mons-peliensis* we have another species that varies considerably. In general it may be described as a rather dense little bush of some 3ft. with bright green, rather narrow leaves and white flowers about 1in. across with a yellow blotch. It has a twin sister in *C. florentinus*, with narrower leaves and which is slightly smaller in all its parts. Both of these are admirable for the rock garden or the top of a dry wall, and they are always most redundant bloomers. They have proved quite hardy here under most trying circumstances. To this indispensable couple I may add *C. rosmarinifolius* (often classed with *Helianthemum*), for it is decidedly one of the best of the dwarf white. As the name suggests, the foliage is narrow, much like that of *Rosemary*, and it makes a neat, compact bush about 2ft. high, spreading, it may be, to double that distance in diameter. *C. rosmarinifolius* is always the first to flower with us, and from April onwards for many weeks it maintains a most amazing succession of pure white flowers about the size of a shilling. This is also as hardy as any *Helianthemum*.

Among the red-flowered *Cistuses* one of the best, giving hardiness, habit and colour first consideration, is *C. Gauntletti*. This is of garden origin and much after the style of *C. crispus*, but we have found it more robust, and while the foliage is hardly as grey and velvety as the latter's, the 2in. flowers are quite as fine a colour, being a dazzling rosy-crimson. *C. Gauntletti* perhaps more closely approaches *crispus* *Sunset*, but again it has even brighter flowers and a tougher constitution. Of their type the three just mentioned are, I believe, the best for the average climate; but the more tender *C. vaginatus*, said to come

from Madeira, has even larger flowers of a brilliant rose-carmine, centred with a bold tuft of golden-yellow stamens. The leaves of *C. vaginatus* are distinct, being peculiarly long-stemmed, large, willow-like and hairy.

C. villosus (*incanus*) is another Mediterranean with flowers of a lively pink, and *C. creticus* appears to be a form of the same thing with blossoms of a deeper tint. Hardly distinguishable in some forms is another of this set, *C. undulatus*, having wavy-margined leaves. All are fairly hardy in all but cold climates. Like most of these red-flowered *Cistus*s, however, *villosus* and its forms do not seem to be long-lived, and a stock of cuttings should always be kept in hand. This also applies to *C. albidus*, another grey-leaved kind from Southern Europe, whose bright rose-coloured flowers have an admirable background in the white tomentum which covers the leaves. All these have an upright habit and attain a height of 2ft. to 4ft. Needless to say, they must all have sun and a hot, dry soil.

C. purpureus stands in a somewhat isolated position among its kind, for while its foliage is greener than that of most of the red-flowered kinds, its enormous crimson-purple blooms have a deep blood-red blotch at the base of each petal. Though not so hardy as some, *C. purpureus* is such a distinct, beautiful and prolific species that no one who attempts *Cistus*s at all can afford to omit it from his collection. It is well, however, always to see the plants in flower before purchasing, for even in *purpureus* there are great differences in the colour and size of the blooms.

Strictly speaking, I believe, there are no yellow *Cistus*s, but I must make custom my excuse for including in my list a few of those yellows popularly classed with the genus, but sometimes listed as *Helianthemum*s. An easy first among these is the very lovely *C. formosus*, excellent for a wall or other dry place, with a loose, trailing habit, small grey leaves and wonderful golden yellow flowers which open flat as if the better to show the fine dark chocolate ring at their base. Then we have *C. f. unicolor*, which closely resembles the type, save that the blossoms are pure yellow throughout. Next to these in order of merit I would place *C. halimifolius* and *C. algarvensis*,

whose flowers might be described as miniatures of *C. formosus*; but these two are of denser growth than the last named, and the blooms are borne at the ends of long stems rising clear of the foliage. *C. halimifolius* is the larger and more robust of the two and has stood some severe winters here without injury. These are no less

prolific in their blossoming than others of their tribe and quite easy in any free soil and sunny aspect. With a mere mention of the dainty little *C. alyssoides*, with its tiny yellow saucers and orange spots, I must conclude, lest I become wholly engulfed by the *Helianthemum* clan. A. T. JOHNSON.

BEDDING OUT

BY GERTRUDE JEKYL, V.M.H.

WE hold to the old term for putting out the summer flowers, although our gardens are no longer dependent on the tender plants alone. We use them now in quite different and more sensible ways, whether as companions and auxiliaries to the hardy perennials or in spaces by themselves. In what we may now call the bad old days the object was to make a bright show for a scant three months in the more important parts of the pleasure garden, leaving them bare for the rest of the year, or, at best, planted in autumn more or less unsatisfactorily with spring blooming flowers. I have no desire to depreciate a bedded-out garden of the older kind when it exactly fits a need, and especially when it is done with the spirit of enlightenment of our present taste and knowledge. Many a great house has an important parterre in close connexion with the design of the building, and the flowers with which it is to be filled are only wanted for display after the London season. But, in this case, by means of the better ways that we have come to know of late years of arranging masses of colour, and also by the much wider range of material provided by our growers, the careful designer has more freedom of hand and has been enabled to redeem the parterre from what it too often was—a mere garish display—to a delightful presentment of colour beauty.

Even without having a parterre of formal design there is plenty of opportunity for a good use of the tender plants if it is decided to have them in a place to themselves. In my own case

there is a three-cornered piece of ground where we try for good effects. It has a kind of axial backbone about 4ft. wide, raised by means of a couple of courses of local stone and filled with permanent plants of solid aspect—*Yucca*, *Phormium*, *Crinum* and the great *Euphorbia Wulfenii*. The rest of the space is chiefly for Dahlias, Cannas, Gladioli, Pentstemons, Antirrhinums and Geraniums. A high wall on one side is made to play its part in one of the chief effects, for here there is a long stretch of brilliant red, and it is tempered and harmonised and enhanced by an intermixture of ruddy foliage richly dark. On the wall a *Prunus Pissardi* is stretched out to cover some square yards, toning delightfully with a tall old Dahlia of deepest claret colour; then come strong red Dahlias grouped with more bushes of *Prunus Pissardi* and *Ricinus Gibsoni*; then dark-foliaged Cannas and tall Snapdragons with bloom of deepest red velvet and dark leaves; then lower scarlet Dahlias leading to a front mass of scarlet Geranium Paul Crampel. A streak of Irisine runs behind these, and among the Geraniums is a French variety of *Love-lies-bleeding*; not the usual large magenta one, but the same plant with a much lower habit and of a dusky red colour both of leaf and bloom that makes a dimly glowing ground for the more brilliant flowers.

How I wish that such a thing existed as a Dahlia with reddish foliage something like that of the dark Snapdragon or the red-leaved scarlet Lobelia, for the green of the Dahlia leaves is in itself uninteresting and is obtrusive in my colour arrangement.

After the harmony of strong reds the colour passes through paler tints to a region of white and yellow. Here at the back are Dahlias, the tall single Victoria with the fresh-looking green of striped Maize; then some tall white and pale yellow Snapdragons leading to white pompon Dahlias and the pretty kind, *Lady Primrose*, a plant of weak habit that easily allows it to be trained almost flat on the ground; also Cannas, pale of leaf and pure yellow of bloom, and double white Marguerite; and near the path a mixture that is always satisfactory. It is a groundwork of the variegated form of *Mentha rotundifolia* intergrouped with *Calceolaria amplexicaulis*, the *Calceolaria* rather thicker towards the back. Quite to the front are little patches and single plants of the formerly much misused Golden Feather Pyrethrum. Some of this is allowed to flower, for its white bloom, yellow centred, helps the picture; in other plants the flower is nipped out the better to show the yellow foliage. The Mint is tipped three or four times in the season so that it grows bushy and does not flower.

In the perennial flower borders the tender plants combine with the permanent ones and greatly help to lark up and carry on the blooming season. At one end of a long border, in a region of blue, white and pale yellow, there is a general hilling of white and yellow Snapdragons and the primrose-coloured African Marigold, while the front spaces are completed with the pretty Cape

A BEAUTIFUL ROCK ROSE, THE PERHAPS MISCALLED CISTUS PURPUREUS.

Daisy, *Agatheæ cœlestis* and the dwarf *Lobelia Cobalt Blue*. Then, where in the middle of the border's length the colouring is of orange and red, the main filling is of the splendid orange African Marigold with the fiery Snapdragon Orange King, Scarlet *Salvia*, and the rich brown

and orange dwarf French Marigold. At the farther end, where the colour is purple, white and pink, with grey foliage, there is tall and dwarf *Ageratum*, tall white Snapdragons, and pink Ivy Geraniums here and there at the border's edge.

JUNE ROSES AND DRY WEATHER

BY the term "June Roses" I refer to the real Roses of June, the earliest of their race to flower, most of them being of the single or wild type. And I am constrained to write of them now with the object of drawing attention to the extraordinary manner in which they have resisted the May—June drought of this year, following the still more severe trials of last summer. In so doing I hope, incidentally, to express my humble gratitude for these adorable things and for the brave and cheerful faces they have maintained during a most trying ordeal. Also, one may express the wish, supposing there are any readers who think they cannot grow Roses because they have not got the right kind of soil and sufficient moisture, that they will, on scanning these lines, realise the fact that it does not matter how dry or poor their soil may be, Roses will prosper in it if they select the right kinds.

Among the first blooms to open here are those of the delightful *R. Hugonis*, which is content with the poorest of stony soil, and whose gracefully hung branches have been wreathed with fragrant sulphur yellow flowers for several weeks.

That fine old single, one of the best of its kind ever introduced, Paul's *Carmine Pillar*, has been enveloping an old stump with a gorgeous array of its brilliant colour throughout the early part of the month, and though its roots are in a sharp slope of thin soil so dry that large bushes of double *Corse* close by have perished of drought, it could hardly have done better. In an equally torrid position the splendid Austrian Copper, in fiery orange-chrome with a pure gold reverse, has once again proved itself to be both the sun-worshipper and drought-resister that its red-hot complexion suggests. Comparisons may be particularly odious when speaking of such Roses as these, for they are incomparable; but there is a splendour so glowing and wholehearted about a good form of Austrian Copper which is transcendently beautiful.

Austrian Copper has, however, anything but an aggressive colour. We have it in conjunction with some of the Irish singles and such Briars as

Lady Penzance (which owes its warm colouring to the Eastern beauty), *Persian Yellow*, the Scotch Rose and others, and the colour blend is a most

A FINE FORM OF THE SCOTCH ROSE, *ROSA SPINOSISSIMA*

harmonious one. All these just mentioned are also happy enough on our loose, shaly banks, and are ardent sun-lovers, though the *Persian* has a way of turning a little weary from over-production in prolonged dry weather. Near to these are also some of the *rigosas*, none of which seems other than delighted with the heat and the drought. Few Roses are so richly fragrant as these, and their handsome foliage is refreshing to behold when less hearty plants are wilting under an unsparring sun.

R. alpina is a choice species for a fairly open spot in the woodland or wild garden, and its spineless stems will bear their soft emerald foliage and bright crimson flowers throughout the most trying weather without complaint. Not less indifferent to dryness is *R. spinosissima*, the sweet little Burnet Rose, one which in its best form is a great improvement upon its wild representatives. For associating with Heaths and other lowly things which enjoy full exposure a group of

Burnet Roses, their arching branches of tiny bronzy-green leaves wreathed from base to tip with large creamy white blossoms, can be very delightful.

Where one can afford to do so, our native Sweet Briar (*R. rubiginosa*) should always be given a place, but some forms are better in colour than others. Another indigenous species well worthy of garden quarters is *R. villosa*, for the brilliance of its rose-crimson flowers; and, under some circumstances, one might venture to include the large and elegant *R. arvensis* which gave us the Ayrshires. There are some really fine forms of the common Dog Rose, but this is unsuitable for most places, and do we not already possess its admirable daughter, *Una*, perhaps the most enchanting of all trailing singles in white? These natives are all drought-proof and easy anywhere if grown on their own roots, and the dwarfier kinds can be put to serviceable use in providing thin shelter for other things on sun-beaten banks.

Somewhat after the same model as *Una* is *Jersey Beauty*, a large single, opening early in a cool yellow and going off white. This is a Rose with a constitution equal to that of *Carmine Pillar*, an evergreen foliage of rare beauty and a temper that will put up with anything. *R. berberifolia Hardyi*, with *Cistus*-like flowers, rich yellow with a crimson blotch, is another that loves a hot, dry place; but, unlike all others mentioned here, it is apt to get fidgety in winter and perish. It has just disappeared with us in this way; but a very lovely form of the same thing, which is stouter, bushier and hardly less pretty, which bears the name of *Hebe's Lip*, is quite content and happy in soil of a starvation character. This has a single flower, creamy-white with a well defined Picotee margin of blood-red to each petal.

The unique and very splendid *Rosa Moyesii* is also an early bloomer and one that, so far, has not made any serious objection to a thin, hot soil; but how long it will be able to carry on and give of its best in such conditions has yet to be proved. Towards the later part of last month, yet before the great majority of Roses are in flower, *Naiad* opens its large goblets of ivory-blush in an open space in the woodland where, despite a rather spare habit, it makes a pleasing feature. At the foot of an adjacent Heather bank we have a little collection of other and very fragrant kinds, most of which possess more than a suggestion of damask "blood." *Hebe's Lip* is among these and so is the most sumptuous *Rosa Mundi*, *Village Maid* and the once familiar *York and Lancaster* with its quaint stripes of white and pink and delicious fragrance. A few semi-double and unnamed strangers from Eastern Europe also claim the hospitality of this little group, and here, too, is the quite dwarf and bushy *William III*, a miniature Scotch Rose with crimson blooms, and the ruby-stemmed *R. nitida*, the autumn foliage of which is always such a joy.

None of these Roses, let it be said in conclusion, ever get any of that attention usually bestowed upon the more ornate inhabitants of the orthodox rosery. They were put into our shaly soil with a little leaf-mould or vegetable compost to help them over their first summer, after which they must practically tend for themselves as the wild Roses of hedgerows do. That they have succeeded beyond one's expectations I have already said, and so long as we have them "the summer month that brings the Rose" will always be something more than a tradition. It never would have become a tradition had the peculiar charm of wild Roses and those of generations gone not been so largely overlooked. The heps of many of these single Roses are delightful. N. W.

CORRESPONDENCE

COLOUR EFFECT IN THE FLOWER GARDEN.

SOME clumps of *Pæonia officinalis*, the old early *Pæony*, that had long shown signs of deterioration, were necessarily neglected during the years of the war. They were in a very poor state when they were taken up two years ago, but a special border was prepared for them—they are great feeders—and they were carefully planted. A good manurial mulch and occasional watering kept them safe during last year's drought and helped to give them nourishment. This spring it was a pleasure to see their glad response to good treatment. Early in April the thick red snouts pushed up with an assurance of strong bloom, a promise well fulfilled by the end of May. They are in the three usual colourings of strong crimson red, deep rose and palest pink, turning to a dull white. These three different forms give quite enough variety of colouring to the little special border, and the quality of colour is so fresh and gay that there is no need for any other bright flowers to be near. Their companions are, therefore, all white, and nothing could suit them better. Just behind them are some little bushes of *Deutzia gracilis* and *Olearia stellulata*, and beyond that white Broom. Here and there among them are plants of the large white Columbine, closely followed by white Foxglove. The whole gives a pleasant picture of simple, joyous flower effect, with a feeling of being unlaboured and almost spontaneous.—G. J.

ALONSOA MUTISII.

I WOULD be greatly obliged if anyone who has grown this delightful half-hardy annual would tell me what colour it is. Is it a pale flesh-pink or a soft rose-pink? I fancy in an ordinary way it is a pale flesh-pink, because, when I commenced to grow *Mutisii* two years ago all the plants save one were more or less of this shade, and it was only this one that had soft rose flowers. I am trying to establish a strain of this deeper colour. Last summer, to my surprise, a small proportion of plants had red flowers, which seemed exactly like those of the well known *Warszewiczii*. Whenever I write this hard name, *Alonsoa Warszewiczii*, I must say I do sympathise with the old lady in his village who told Mr. Tom Aldersey that of all the plants he had given her, she liked "Alfonso Whisky-and-Soda" the best. Perhaps it will be useful and seasonable to say that this plant with this break-jaw name does excellently in pots and might be used as a change from *Schizanthuses* and *Clarkias* for greenhouse decoration. Perhaps some will say, *Schizanthus* I know, and *Clarkia* I know, but what are you like? The *Alonsoa* will answer: "I am a very graceful plant with small toothed deep green leaves and bright red flowers, a wee bit like a *Schizanthus*. I bear pinching when young, and if this attention is vouchsafed to me I become nice and bushy. I cannot produce the same solid masses of colour that my rivals do, but all the same my more subdued show is very graceful and in the opinion of many very charming, and a welcome change from *Clarkias* and *Schizanthuses*."—MÆLOR.

ROSE MARECHAL NIEL.

HOW rarely one sees even poor blooms of this grand Rose, and still more rarely really good ones. From my early days, when I first enjoyed the delicious fragrance of the blooms of the *Marechal Niel* and the full-centred specimens in Cheshire and Lancashire, I have been very fond of the variety and striven to

grow plants, sometimes with success and sometimes without. But I would never think of giving up efforts. The flowers are worth trying for, and I am surprised that more Rose-lovers do not grow this variety.

When first I came to Hampshire I found a specimen growing on a wall facing west and otherwise sheltered, too, but the buds only partly developed and were almost green in colour, not much trace of that rich golden yellow one so much appreciated. About the same time I was on a visit to Cheshire and was told that there was a splendid plant growing on a cottage wall in the district. I did not rest till I had inspected the plant. It was, indeed, a very fine, healthy specimen bearing leaves of large size and very green in colour with blooms to correspond; the soil was a heavy loam. Outside, of course, this Rose is always very uncertain in its growth and flowering qualities. Under glass one can to a great extent control the growth but not the canker. Judging from my own experience, I have found

was not my own method but that of another cultivator.

With reference to canker, there is one instance, to me exceptional, that of a plant quite filling a span-roofed greenhouse about 20ft. long and 12ft. wide. It belongs to a farmer in the North Midlands. The canker had formed a lump on the stem, where budded, about the size of a very large Coconut 2ft. or so from the ground. The stock measured about 1½ ins., through, the Rose stem above the canker about ¾ ins. The plant was very healthy, and the owner said it had never failed to bear blooms profusely for the past twenty years. The soil is a medium heavy loam.—GEORGE GARNER.

THE REGELIO-CYCLUS IRISES.

AS there is so much controversy about these remarkable and beautiful flowers, the enclosed picture showing a breadth of them in the Zwamburg Nursery of Mr. C. G. Van Tubergen, jun., near Haarlem, Holland, may be of interest. Mr. Van Tubergen shares with the late Sir Michael Foster the honour of originating this race of hybrids, which, if hardly such easy garden plants

REGELIO-CYCLUS IRISES GROWING IN THE OPEN GROUND AT VAN TUBERGEN'S NURSERY.

canker appear generally about seven years after the Roses are planted, whether in pots or borders. My best results have followed planting in an outside border and training the branches on a back wall of a greenhouse, the exposed portion of the stem being wrapped in haybands during the winter months.

Another plan, followed with success for a number of years, was to propagate young shoots in spring in bottom-heat and to grow on the resultant plants in pots—never larger than 6 in. ones, and to force them in due season, discarding the plants before canker showed and replacing them with young stock, the latter being raised in small numbers every spring.

I believe the finest blooms of *Marechal Niel* were borne on plants trained up the back wall of a lean-to vinery and treated as cordons about 1ft. apart, every other plant being cut down almost to the ground in alternate years, the annual growth being from 7ft. to 10ft. This

as the Bearded *germanicas* and *pallidas* or the forms of *Iris sibirica*, are, compared with the pure *Oncocyclus* forms, quite readily cultivated. A warm soil, well enriched—but not with fresh manure—and protection from winter wet are the main desiderata. H. H.

SOME AFTER-EFFECTS OF THE DROUGHT.

IT is very interesting to note the after-effects of the long drought of 1921 on many plants, trees and shrubs. Some of them I have never seen with such a wealth of bloom as this year. The *Daffodils* were a glorious sight, partly due, of course, to the lateness of the season causing both early and late varieties to bloom together; but apart from this many rather crowded clumps of bulbs which have for a few years flowered very poorly gave a quite good show, and masses of bulbs under trees and in grass, which were more

thoroughly dried than those in borders could not possibly have been better. Tulips, too, were grand, and many offsets planted in the spare border are flowering. A good-sized patch of *Gentiana acaulis* (*Gentianella*) in the garden here which has not been disturbed for several years was crowded with blossoms. So easy is the cultivation of this when compared with nearly all other *Gentians* worth growing that one almost apologises for making any note on it. It withstands disturbance almost with impunity, and in proof of this I may say that some here which had become very crowded were thinned out last spring to extend the group, and in spite of the long drought the casualties among the clumps moved were very few, though, as was to be expected, those which survived the ordeal gave but few flowers this year. The soil in which they grow is cool, without stagnant water in winter. I have found they benefit by a top-dressing of well decayed leaf-mould and cow manure in spring and coarse river sand in autumn. This, and weeding, is about all the attention required or given.

In the shrubbery the Crabs and Brooms have bloomed as never before. From a distance the Brooms appeared to be a solid mass of colour and broke down under the weight of blossom. *Loniceras*, too, are much better than usual; double *Cherries* a sight to remember.

It would be interesting to know how these things have done on lighter and shallower soils, where the effects of the long drought would be more severely felt; also on stiff clays, which crack badly and so damage the roots.

To wander from the shrubbery to the kitchen garden and orchard, one feels compelled to ask why, while the Crabs seem to have eclipsed all former efforts, the Apples were so sparing with blossom? They were very patchy and disappointing; a very few had a good show; some were very poor, and many had none worth mentioning. *Quinces* flowered splendidly, and so did *Pears*, *Plums* and *Cherries*; but it is to be feared the crops of some of these will be very light, especially the self-sterile varieties, as the honey bees and other insects were unable to be abroad owing to the bad state of the weather while the trees were in bloom.—H. C. Wood, *Lingfield*.

THE HIPPEASTRUMS.

I HAVE read with interest the article on *Hippeastrums* in *THE GARDEN* for June 3. I have found raising seedlings a delightful experience. Some years ago I purchased a collection of ten bulbs from a large firm, who were selling off, and stated the collection was a prize winner. Among them was one of great beauty—very dark crimson—good habit, with a wonderful sheen. I happened to have another very fine bulb of a different habit. I crossed these and waited with great hopes until they flowered 2½ years after sowing seed. I hoped I might get out of fifty plants two or three good ones, but I was amazed to find that with hardly an exception, I had improved on the parents. Practically all the bulbs flowered the same spring. I have since raised another batch with similar results and had a superb display this spring. I have found the culture very simple, except that I have been troubled with a disease that colours the leaves and roots with a reddish tinge, and in some cases caused the flower stems to burst. The method of culture in your article this week is practically the same as that I have followed, but there are one or two hints that I am glad to know of.

I find few people are aware of the glory of a group of these lovely flowers, nor of the pleasure of raising them from seed. I imagine the difficulty would be to obtain really first class seed, and had

I not my own I should not know where to get it.—G. HUNNYBUN.

[Seeds of *Hippeastrum* may be obtained from leading seedsmen at home and abroad.—ED.]

THE ADORNMENT OF CREEPER-ROOT FILLED BORDERS.

MANY houses, and especially old ones, have their walls well furnished with climbers, and the difficulty of finding suitable plants to furnish the borders is often great. Generally one sees the attempt made with the ordinary bedding plants, and very rarely is it wholly satisfactory. Much labour is needed in improving and watering the soil to enable the plants to grow, and this naturally encourages the climbers to form a still greater mass of fibrous roots near the surface and so increases the difficulty in the future. We have one such border here on the west side of the house in which are growing old-established plants of *Pyrus japonica*, *Rhus Toxicodendron*, *Magnolia grandiflora*, *Wistarias*, *Vitis purpurea* and a *Rose*. About eight years ago a part of the

MASSSES OF *NEPETA MUSSINI* IN A CREEPER-ROOT FILLED BORDER.

border was planted with *Nepeta Mussini*, and the result was so encouraging that the whole was filled with it and gives a very charming effect with the minimum of attention. The colour of both flower and foliage harmonise well with the old stone of which the house is built. I enclose a photograph which shows about two-thirds of the border, and many of the plants are eight years old. It is one of the easiest plants to propagate. The young growths may be pulled out in early spring when gins, or so in length and inserted in pots or pans of sandy soil and placed in a greenhouse or frame. They root quickly and may be planted out rather closely to give a good effect the first season and thinned out for the second year. The spare plants may be used elsewhere. Old plants may be divided, but the cuttings, I think, give better results. When in bloom it is a great favourite with the honey bees, which work on it throughout the day, filling the air with their cheerful hum.—H. W.

HAILSTORM RELIEF FUND.

WHILE sympathising very deeply indeed with the Tunbridge Wells growers in the losses sustained in the recent severe storm, one cannot

help feeling that there should have been no necessity for a public appeal to relieve them of distress in times which are more or less distressful for everybody. The Hailstorm Insurance Corporation has been established at least twenty-five years, and the knowledge that the premiums it asks are extremely low, and that its payments for damage done are instant and generous, should have reached the growers of Tunbridge Wells, as it has the growers of other districts, years ago. They could then have safeguarded themselves against loss and an appeal to public generosity. Or it may be that they are in parallel case with a friend of mine who allowed his hailstorm insurance to lapse last year, after paying for a long period, because he had suffered no loss. He now bemoans his false economy, but admits his fault.—W. H. L.

BRITISH-GROWN GREENHOUSE BULBS.

ONE cannot put one of those ample title pages of a past age as the heading of a paragraph in a modern gardening paper. All the same I should like to have done so in order to explain in a short, general sort of way which are the particular bulbs

that are in my mind; and further, to point out the satisfactory way in which they may be grown under glass in Britain. As I anticipate the cool greenhouse will come more and more to the front as an adjunct of twentieth-century gardens, it is well to remind ourselves that there are a good many bulbs which flower in the earlier half of the year that can be successfully grown in such structures from year to year, so that after the initial outlay we can carry on without spending any more money—a not unimportant consideration in these days of more or less entoreed economy. The families that are in my mind are *Freesias*, *Lachenalias*, *Ixias*, *Sparaxises*, *Brodieas* and *Babianas*. All the ordinary greenhouse varieties of these can be grown successfully at home, as I have proved in my own garden. The usual and, I must own, the greatest difficulty is the aftercare of the plants when the flowers are over. They need feeding and watering until the foliage begins to die down. They then require a thorough baking in the sun and to be kept perfectly dry until planting time comes round again. All this means pots of leafage with no blooms.

Now, bloomless pots are not wanted either before or after their period of blooming, if the greenhouse

is to be a blaze of colour. Here is the difficulty, and where there is but one house it is a very real one. Either the idea of a big display must be scrapped, or very skillful use must be made of cold frames. If a small house can be given up to the growing on and the ripening off of the bulbs, all difficulty disappears. Or if the one house need not be kept always gay, but can be used in a more utilitarian way, the difficulty is very much minimised, and with a good cold frame is practically

nil. I have written this rather bald statement of facts to rub in the principle that forewarned is forearmed. Provision must be made for every period of the growth of the bulbs. What happens to them up to and after their flowering is very important, but it is no use attempting to have home-grown bulbs if we are not able to provide adequately for their requirements. All the genera mentioned above provide many varieties most suitable for a cool greenhouse.—JOSEPH JACOB.

more receptive condition than when over-moist conditions prevail. When a sufficient number of fruits are set and swelling becomes visible, a thorough watering with tepid water should be given, closing the frame as early as possible after syringing the foliage. As the fruits increase in size a suitable stimulant may be given the plants, always being careful to see that the water used is tepid.

The Flower Garden.

Shrubs.—Flowering shrubs, such as Deutzias, Berberises and Lilacs, may be judiciously pruned immediately they pass out of flower. This induces a vigorous growth which will ripened will materially add to next season's display of flower.

Wallflowers.—Sow seed now so as to secure nice bushy specimens for transferring to the beds in the flower garden by the end of October. Grow in fairly firm, not overrich soil, as over-feeding tends towards that softness of growth which is so easily damaged by the vagaries of our winter weather.

JAMES McGRAN

(Gardener to Sir Henry H. Hoildsworth, Bart.),
Coodham, Kilmarnock.

GARDENING OF THE WEEK

FOR SOUTHERN GARDENS.

The Kitchen Garden.

Asparagus.—Just when to cease cutting the "grass" for daily usage must be determined to some extent by the earliness or lateness of the season, and also in many cases the requirements of the establishment must be taken into account; but although no notice need be taken of advice which stipulates that the cutting must cease by a certain date, it is wrong to continue the cutting later than the latter part of this month, or sufficient time will not be given the plants to grow and properly develop a good supply of haulm by the end of summer. See that the beds are thoroughly clear of weeds, and if such can be spared a dressing of well rotted manure or a suitable fertiliser will greatly assist in the building up of the plants for another season. The stronger growths should be staked, or a few pea-sticks of suitable length will answer.

Celery.—The plants to form the main supply of roots may now be placed in the trenches as they become ready. The bed or frames where the young plants are growing should be well watered previous to lifting so that as good a ball of soil as possible may be lifted with the plants. The distance allowed between each plant should be from 6 ins. to 12 ins., and as planting proceeds a good watering should again be given the plants. Celery delights in a good spraying over each evening after hot days, and an occasional dusting of soot is beneficial and helps to ward off fly. Celery plants which were planted in the trenches some time ago should also have liberal supplies of water if it can possibly be managed.

Parsley.—A sufficient supply of this should be sown now to yield late autumn supplies and also to provide plants for pricking out in favoured positions for winter use. As Parsley is sometimes a trifle fickle in growth, it is a good plan to sow in two positions and endeavour always to have an ample supply of this indispensable kitchen commodity on hand.

The Flower Garden.

Early Flowering Shrubs will need attention as they pass out of flower, for with many of them what pruning and thinning out of shoots is necessary may be done then. In dealing with such plants as the flowering Brooms, for instance, it is not always necessary or even advisable to adhere to any fixed method of pruning, but make due allowance for position and surroundings. It is by no means rare to come across in some small gardens in Surrey many fine plants which have never had a pruning since they were planted and are yet annual objects of much grace and beauty.

Delphiniums which are expected to yield a second crop of spikes must have the early ones removed as soon as ever they are on the wane, so that the whole of the plants' energies may be concentrated in the new growths pushing from the base. This is not a practice to be recommended as an annual one, and when it is done see that the plants are well supplied with water during dry spells and a liberal mulch given also, or exhaustion will soon set in.

Fruit Under Glass.

Scalding Grapes.—The two varieties which are generally the most troublesome through scalding or scorching of the berries are Muscat of Alexandria and Lady Downe's Seedling, and the time when the evil usually begins is when the berries are about half grown. The best way to guard against the scalding is carefully to avoid a too sudden rising of the temperature, particularly when the atmosphere is heavily charged with moisture. In other words, air the houses freely in advance of a rising thermometer, not waiting until the maximum has been reached before airing liberally.

The hot-water pipes should be kept always luke-warm should this trouble of scalding commence, for in this means a more buoyant atmosphere is maintained. H. TURNER

(Gardener to the Duke of Northumberland),
Albury Park Gardens, Guildford.

FOR NORTHERN GARDENS.

The Kitchen Garden.

Mushrooms.—Nice specimens of these are appreciated at any season, therefore in establishments where manure is available it should be collected and by repeated turnings put in condition for forming beds which will ensure supplies of Mushrooms during September and October. The bed should be trodden firmly, and when the temperature is about 80° spawning should be attended to. Cover over with a layer of fine soil, and as an efficient check to evaporation a covering of straw should be given.

Broccoli.—Attend to the planting of spring and early summer varieties. Owing to the severity of the climatic conditions in the North it is futile to plant winter sorts, more especially where cold, unkindly soils prevail.

Late Potatoes should be well worked between the rows and a dusting of approved Potato manure or soot given before the final earth up. In northern areas Potatoes are promising well, and if given generous cultivation should provide a bounteous yield.

Seakale.—Plantations of Seakale should be encouraged with a light surface dressing of sulphate of ammonia, stirring it lightly in with a cultivator or hoe.

Broad Beans.—Pinch the tops of plants that are well set with pods, as this materially assists in their development.

Tomatoes.—Continue to assist Tomatoes that are swelling their fruits by giving regular waterings of liquid manure. Where the plants are at close quarters the points of the leaves may be pinched off so that more light and air may be allowed to reach the trusses. Opinions differ regarding defoliating Tomato plants, but if the work is not carried to excess the fruits colour more quickly and richly. But if too severely dealt with root action is checked and the crop suffers accordingly.

Parsley.—Sow seed now for winter supplies. Choose a sheltered border for this sowing so that pickings from the open may be as prolonged as possible. When thinning the rows a quantity of the seedlings should be transplanted into a cold frame for use during wintry weather.

Saladings.—Nice crisp saladings are always appreciated, so fortnightly sowings of Radishes and Mustard and Cress should be made. Regular sowings of both Cos and Cabbage Lettuce should also receive attention.

The Hardy Fruit Garden.

General Work.—Use the hoe freely among Gooseberry and Currant bushes so that the ground may be clean and porous before the necessity for netting the crop arrives. Keep a watchful eye on young bushes for attacks of red spider or caterpillar and syringe with Quassia extract on their appearance. Thin fruits of choice Apples and Plums on walls and disbud where necessary.

Fruit Under Glass.

Melons in Frames.—With plenty of sun-heat plants in frames will be making rapid growth and producing abundant fruiting laterals. Stop these simultaneously at the second or third leaf beyond where the fruit is set. To assist setting ventilation should have attention early on fine days so that all moisture may be dispelled and the flowers and foliage be in a dry condition before setting takes place. The pollen of the male blooms will then be more potent and the organs of the female flower will likewise be in a

GREENHOUSE AND CONSERVATORY.

Humea elegans.—A small sowing should be made this month, standing the seed-pots in a cool greenhouse, where they should be shaded until the seeds germinate. When large enough to handle prick off singly into thumb pots, afterwards potting them on as they require it. Many cultivators fail with this plant, this probably due in most cases to careless watering, as care is required in this respect at all stages of the plant's life. The sowing for the main batch of plants should be made at the beginning of August. It is not generally known that this plant causes a kind of rash or eczema when handled by some individuals. In this respect it resembles *Primula obconica*.

Malmaison Carnations.—Strong, healthy plants should be selected for layering as they pass out of flower. Layering is best done in cold frames, using a light compost with plenty of good leaf-soil added. The plants should be well watered before they are turned out of their pots. They should be firmly planted, and if the shoots are at all long it may be necessary to lay the plants down on their sides, and thus render the operation of layering easier. If stock is plentiful only the strongest shoots should be retained for layering. Afterwards the frames should be kept close for a week or so and shaded during bright sunshine. Air may then be gradually admitted. When roots have formed the lights may be removed. As they pass out of flower healthy young plants should be selected for potting on as specimens. The potting soil should consist of good mellow loam, and where it can be procured old mortar rubble may be used instead of sand to render the whole porous, for it must be remembered that all Carnations enjoy lime. Crushed oyster-shells may also be used with advantage. With the exception of a 6 in. potful of fine bone-meal to every bushel of soil, no manure should be added to the potting compost. The plants should be firmly potted, and careful watering is necessary until they are well established in the new compost.

Arctotis aureola.—This beautiful South African plant is by no means so popular as it deserves to be. This is no doubt due to the fact that most cultivators find it very difficult to propagate by means of cuttings, and it is not generally known that it is easily propagated by means of layering at this or any time during the summer in a cold frame, or it may be successfully done outdoors. As advised for Carnations, the plants are best turned out of their pots and the shoots layered in the usual way. *Arctotis aspera* and *A. revoluta*, although not such showy plants as *A. aureola*, are still well worth growing for the cool conservatory. They are both easily propagated by means of cuttings, which may be inserted any time during the summer months in a close case in a cool house.

Primula Forrestii.—Generally speaking, this Chinese *Primula* has not proved successful outdoors in this country. It is, however, worth growing for the cool greenhouse. In addition to its deep yellow flowers, its rugose leaves are quite handsome. It is easily raised from seed sown in a cool house. Its seed is sown at this time good plants should be secured for next year. This *Primula* is a perennial, and is longer lived than most members of the genus. With age it forms several crowns, which affords means of increasing the plant by dividing and rooting the crowns in a close case. As this *Primula* grows on limestone

cliffs, lime in some form is necessary in the potting compost. For this purpose old mortar rubble is as good as any, as it serves to keep the compost sweet and porous.

Agapetes buxifolia.—This plant, which produces pretty, red tubular flowers in profusion, is not so generally cultivated as it should be. It is easily propagated at this time by means of cuttings, which root readily in a close case in a

cool house. It makes a neat bush when grown in pots, but is seen at its best when planted out in a shallow bed of sandy peat in a cool conservatory. Although enjoying ample moisture at the root, drainage must be free and rapid, for in its native state this plant is partly epiphytic, hence stagnant moisture at the root soon proves fatal.

J. COURTS.
Royal Botanic Gardens, Kew.

UNCOMMON PLANTS AT THE BATH AND WEST SHOW

THE plants exhibited in the horticultural section of the Bath and West Southern Counties Agricultural Society at Plymouth were one of the chief attractions to the huge crowds, numbering about sixty thousand people, who visited the Show.

Gardening in Devon and this part of England is mostly outdoors, but some of the finest gardens in the country are to be found here. Glorious Mimosa trees, which are only hardy in sheltered spots in many parts of Great Britain, flourish. Mimosa—in the shape of *Acacia pulchella*—came from the Plympton Nurseries of Messrs. Chalice and Sons, as also some *Callistemon* (*Metrosideros*), which are recognised as the popular "Bottle Brush Trees" which here thrive in the open.

Some similar plants came from the Exeter nurseries of Messrs. R. Veitch and Sons, including the beautiful *Davidia involucreata*, the large white bracts of which were some six, long. *Witsenia* (*Aristea corymbosa*), a rare South African iridaceous plant, was exhibited by them, the delightful blue flowers of which are seldom seen in this country. *Embothrium coccineum* and the white *Callistemon alba* were other interesting plants.

Herbaceous plants were shown by Messrs. Wallace all the way from Tunbridge Wells and by Messrs. Blackmore and Langdon, Bath, whose wonderful *Delphiniums* were a sight seldom seen at this date. They also had some gorgeous *Begonias*. Godfrey and Son, of Exmouth, had giant Poppies and Lupins, as well as fine *Pelargoniums*; while Mr. Gullick, of Salisbury, staged *Pyrethrums* so artistically that this plant, which blossoms just when flowers are none too plentiful, must have many new admirers; some daintily tinted Lupins showed them off well. Messrs. Rich and Co., Bath, also had *Pyrethrums*.

Roses (perhaps the harbingers of the first outdoor-grown flowers exhibited this year) were sent from Messrs. Jarman of Chard and the Devon Rosery, Torquay; also a beautiful group from Messrs. Cutbush and Son.

Sweet Peas, well displayed, were exhibited by Mr. J. Stevenson, Wimborne, the sunproof Poppy Orange variety and the sweetly perfumed Wild Rose and *Cynthia* being prominent.

Other interesting plants of the Show were the Sunbeam Poppies from Messrs. Baker, Wolverhampton; while dainty and miniature rock plants in the shape of miniature *Dianthus* and *Anchusa* came from Messrs. Maxwell and Beale and Bowell and Skarratt.

From Dartmoor some extra well flowered *Rhododendrons* were exhibited by Messrs. Bray and Son of Okehampton. One is inclined to associate this plant with sheltered nooks, but this exhibit proves their hardihood. Messrs. Waterer, Son and Crisp also had a fine group.

The Show was open for nearly a week, but despite this and the heat one noted that the Carnations from Messrs. Allwood Brothers and Stuart Low and Co., Bush Hill Park, not only had stood the long journey to the West, but maintained their freshness; even the *Dianthus* Allwood held up nearly as well as the giant and fragrant White Pearl.

St. Brigid Anemones, which thrive so well in Devonshire gardens, were staged by Messrs. Reamsbottom; and vegetables, well grown and tastefully arranged, came from Messrs. James Carter and Co. and Toogood of Southampton.

Orchids are not largely grown in the West Country, but a small exhibit of easily grown

WITSENIA CORYMBOSA.

varieties was sent by Messrs. Stuart Low and Co. from their Jarvis Brook, Sussex, nursery.

Cornwall, whose gardens in places assume a sub-tropical aspect, although so near, sent but one exhibit in the shape of *Cinerarias* from Mr. Hodge, St. Austell; yet the duchy might have shown Oranges picked from the open, and Australian plants and shrubs in great variety. To see a Cornish garden with its giant Blue Gum trees (*Eucalyptus globulus*), *Embothrims*, *Acacias* and specimens of *Dracena indivisa*, to say nothing of Bamboos 20ft. high, is a revelation. Cornish gardeners are not exhibitors, or there would be many more to envy their delightful climate than there are.

This exhibition has been managed for many years by the Rev. A. T. Boscawen, whose delightful garden near Marazion contains many unique plants.

TWO CHARMING SCENES IN WIGTOWNSHIRE

QUITE recently I have visited the beautiful gardens and grounds of Logan House and Castle Kennedy. Logan is one of the most attractive places in the South of Scotland, and its gardens, which now comprise an epitome of the finest flora of the world, are constantly and assiduously superintended by its proprietor, Mr. Kenneth A. McDouall, who has a competent and practical gardener in Mr. McBryde. At the period of my visit the *Rhododendrons* (in which Mr. McDouall and his genial brother, Mr. Douglas, take a very special interest), the *Azaleas* and *Primulas*, and the brilliant miniature beauties that adorn in thousands the exquisite rock garden, including some *Iris*es of distinctive character and early-flowering attributes, were especially impressive. Among the very finest of the *Rhododendrons* were such superbly effective varieties as Pink Pearl, Alice and R. Dalhousianum, of which the last mentioned has, in its individual flowers, the peculiar grace of an Oriental Lily, such as *Lilium Browni*, or *Longiflorum Wilsoni*, while its fragrance is that of *Magnolia Watsoni*, but somewhat less pronounced and more refined. Many of the climbers that adorn the garden walls, and especially in the vicinity of the ruins of the ancient Castle of Logan, were supremely ornamental; while a myriad *Primulas* of charming colour adorned the famous "Ladies' Walk," which leads from the gracious western environment of the gardens to the sea. There are several fine *Magnolias* in Logan gardens, including *Soulangiana*, *conspicua*, *stellata* and *Watsoni*. Of these by far the loveliest is *Soulangiana*, of which I recently saw an especially arresting and commanding representative in Westmorland, near Patterdale, on the sylvan banks of Ullswater—"the English Lucerne."

A few days subsequently to this memorable visit I cycled to Castle Kennedy, which, with the return journey through a tropical heat, culminating in a thunderstorm which I partly experienced, signified a run exceeding forty miles. But if atmospheric conditions were exacting, I was amply repaid. I had the great privilege of being conducted through the gardens and nobly wooded terraces of this "earthly paradise" (which has three exquisite lakes for its perfect adornment) by Mr. R. Findlay, the head-gardener to its proprietor, the Earl of Stair. There I saw, in the first place, beneath the magnificent ruin of the ancient castle, the grandest collection of the Lily of the Himalayas (*Lilium giganteum*) I have ever beheld. Thereafter we repaired through a glorious avenue of Conifers to the pre-eminently beautiful oval lake, which has been called "The Basin" for several centuries, and of which there is a charming delineation, crayon drawn, in Sir Herbert Maxwell's picturesquely written book on "Scottish Gardens." While the *Marliac Nymphs* and snow-white *Arum Lilies* adorn its calm surface, it is at this special and inspiring season of the year, environed by *Azaleas* of gorgeous hues and *Rhododendrons* the varied colours and prodigality of floral affluence of which (especially manifested in such varieties as R. Broughtoni and R. Loder's White) are marvellous to behold. Such pictures of imperial beauty as these are treasures ever afterwards in the memories of Nature-loving men. When these are reflected, with the far-extending shadow of the ancient castle, in the mirror of the miniature lake on a calm, benignant evening, the vista is one the radiant loveliness of which cannot adequately be described.

GREAT AUTUMN SHOW

AT THE

Holland Park Skating Rink, Holland Park Avenue, W.,

OCTOBER 3rd, 4th, 5th and 6th, 1922.

(Not October 4th to 7th, as at first announced).

This Show will combine the Annual Fruit and Vegetable Shows, with a Display of Flowers and Foliage Plants in season at the time, but there is, unfortunately, no room for Sundries or Paintings. As the space available is limited, no very large area can be allotted to any exhibitor and all applications for space for non-competitive exhibits must be received in writing by the Secretary at Vincent Square, Westminster, S.W.1, not later than August 31st.

Cups and Medals will be awarded to meritorious groups, and the Schedule and Regulations will be available shortly upon application.

ORCHIDS

of vigorous habit and superior constitution. A visit to our Establishment is cordially invited to inspect our immense and interesting STOCK RAISED BY THE

PURE CULTURE SYSTEM

Choice Species, Rare Botanical Specimens. Albinos in warm and cool sections also a speciality.

Expert Advice given and all Requisites supplied for the good culture of Orchids.

CHARLESWORTH & CO., HAYWARDS HEATH.

WHITE FLY DEATH.

NO FURTHER LOSS FROM THIS PEST IF YOU USE

CORRY'S WHITE FLY DEATH FUMIGANT

It is unique and differs from all others. NON-POISONOUS. No danger to operator. No apparatus. Simply pour from the container on to the floor of the greenhouse.

FULL DIRECTIONS WITH EACH PACKAGE.

Cheaper and safer than any other Fumigant on the market and absolutely effective against White Fly. Mr. J. B. JACKLIN, Jersey, writes:— "May 31st, 1922.

"Your new White Fly eradicator is simply splendid, and you can recommend it from me, as it is a perfect killer of White Fly."

The "VILLA" SPRAYER

PATENT N^o. 161730.  BRASS CYLINDER 17 IN. LONG X 7/8 DIAM.

"The Villa" Sprayer is now fitted with a new and greatly improved nozzle.

It is connected to the pump with the same sized screw as the old pattern, so that the old one may be unscrewed and replaced by that shown in the cut above.

Instead of the inlet valve being operated by a rubber band a BRASS BALL VALVE has been substituted.

There is nothing whatever to go wrong or to corrode. The liquid may be sucked up from the very bottom of the can.

By loosening and tightening the brass screw the spraying tube may be set to throw the spray at any desired angle, and it is more solidly constructed.

Former customers may be supplied with this new nozzle, post free, 1/6.

Ask your seed man or ironmonger for the "Villa" Sprayer.

PERENNIAL PLANTS FROM SEED

The sooner such seeds can be sown after ripening the better the results.

FROM the point of view of the amateur gardener perennial plants are raised from seed for three reasons. In the first place, raising from seed is a cheap way of obtaining a stock; secondly, it is a procedure full of interest; and thirdly, plants from seed have, speaking generally, a vigour alien to those propagated vegetatively.

The reason that perennial seed raising is so comparatively little attempted is not so easy to find, but is unquestionably based upon an obscure legend that such raising is difficult. With some noteworthy exceptions perennial plants are as readily raised as the biennials (and perennials treated as biennials), such as Wallflowers, Forget-me-nots, Antirrhinums and Polyanthuses.

Seeds of hardy perennials are now offered by several reliable firms, while in most gardens seeds of many species and varieties could with a little trouble be harvested. Of course, a certain amount of consideration is necessary before seed-purchase or harvesting is undertaken. There is little use in raising a batch of *Centaurea montana*, for instance—even should the plant be esteemed—when a large and robust stock may readily be obtained by division. Unless the inclination is set upon systematically devoting a considerable area of ground to the raising of new varieties, it is unwise to attempt the herbaceous Phloxes from seed or the Michaelmas Daisies, both of which habitually produce a large proportion of utterly worthless seedlings. The same may be said of *Veronica spicata*, of which in a large batch hardly two will be alike either in habit or in foliage.†

For seed raising to be worth while it is not necessary that the seedlings come true to type. In comparatively few

cases can this be relied upon with the improved sorts and strains usually met with in gardens. None of those next to be mentioned reproduce themselves true, yet all are worth raising, since the whole of the produce will be healthy and vigorous—an important point this upon new,

imperfectly worked or difficult soils—decorative, and in all ways desirable for the garden.

Such are Delphiniums, seedlings of which are especially vigorous and of good stature; Lupins, which rapidly lose vigour when divided; Gaillardias, which from seed will often stand outdoors

where named kinds are lost each winter; Bearded Irises, very interesting to flower, but plants may be rapidly increased by division; Aquilegias, of which, however, none, except *Helena*, can be relied upon to come true; Campanulas, especially *persicifolia*, *lactiflora*, *pyramidalis* and *carpatica*; Pinks, of which seedlings are very free-flowering but seldom possess the quality of the parents; Galegas, easily raised and generally come moderately true to type; Geraniums, of which the most valuable species for the herbaceous border, *Wallchianum*, varies much in colour from seed, but all the shades are beautiful; Heucheras; Torch Lilies, but species such as *caulescens* or *Northia* come true to type; Everlasting Peas, *Lathyrus latifolius*—seed saved from *White Pearl* will usually "throw back" to give a proportion of pink and rosy purple forms almost all somewhat deficient in size; *Lythrum Salicaria*, *Purple Loosetrife*, of which the rose forms throw a large proportion of rose-coloured seedlings; Oriental Poppies, which should be flowered on a reserve ground before planting in the border; Pentstemons, very interesting if saved from a good strain; Pyrethrums; and Verbasums—*Miss Willmott* always throws a proportion of soft yellow-flowered plants.

The above have been collected together not only because, while varying from seed, they are worth raising, but because they are all readily raised. All may be sown in drills in the open border if a

THE BEAUTIFUL MADONNA LILY, *LILIUM CANDIDUM*, MAY BE RAISED FROM SEED.

A VALUABLE GERANIUM FOR THE WILD GARDEN. *G. ATLANTICUM*.

THE VALUABLE YELLOW-BRACTED RHEUM ALEXANDRÆ.

moderately rich piece of ground can be placed at their disposal which is in the open, quite free from pernicious perennial weeds and moderately so from annual ones. Sowing in drills is preferable to broadcasting, because if the ends of the rows are marked a line or straightedge may be employed to shew the row, and the hoe plied between when the seedlings are still tiny. All these are open border plants, and sowing in a shady corner as often recommended would be detrimental to the health of the seedlings, but shade must certainly be provided until the seeds germinate. Narrow boards or tiles placed over the rows and lifted every day or so for inspection are most satisfactory as giving shade and also conserving moisture. If the ground has been well dug in winter or spring, there is no need to disturb it to any depth—to do so would leave it hollow—but the drills when drawn—depth according to the size of seed, but, generally speaking, quite shallow—should be thoroughly soaked with a fine rose can before sowing takes place.

There are many gardens, especially new gardens, in which well cultivated, moderately rich but weed-free sites are not to be found. In such case it will be much more satisfactory to sow the seeds in pans or boxes in a nice "silky" but not overlight compost and stand them upon an ash bottom in a frame looking north. The whole frame may then be kept close and shaded until the first lots appear, when light and a moderate amount of air must be given, unless they are removed as they come up to another frame. If seeds and seedlings must perforce stay together, the ungerminated boxes may readily be covered with boards or even with folded newspapers.

Herbaceous plants of the same easy culture which come true (or true enough) from seed include *Gypsophila paniculata*, *Geums Heldreichii*, *miniatum aurantiacum* and *Mrs. Bradshaw*; *Aquilegia Helena*, also all true species from *collected* seed; *Artemisia lactiflora*; *Bocconia*, both species; *Cheiranthus Allionii*, best treated as a biennial; *Coreopsis grandiflora*, also short-lived; *Echinops*, but good seed is not produced every season; *Kniphofia*, true species; *Jasione perennis*; *Linaria macedonica speciosa*; *Linum*, all species; *Tree Lupinus* if saved from either yellow or white forms quite away from others; *Physalis Francheti* and *P. Alkekengi*; *Potentilla nepalensis*; *Rheums* of sorts; and *Thalictrum*, all species.

The above list excludes rock garden plants as such. It is hoped to deal with them in a succeeding article. The enthusiastic gardener will wish to know of other perennials likely to repay the labour of raising from seed, even though germination be slow or the culture requires especial care. In the latter category must be placed bulbous plants of all kinds. Speaking generally, new seed germinates fairly quickly, but the seedlings of some species take many years to flower, notably those of the *Narcissus*. The amateur would in any case be well advised to leave the improvement of this flower to those with long experience of the business and the latest seedlings to use for cross-pollination.

The raising of *Tulips* from seed is chiefly interesting if species are raised in this way. A stock may thus be obtained of species which are not often seen in gardens. The seeds should be sown in light, clean, but moderately rich soil either in deep pots or in borders in a specially prepared frame. On no account must any attempt be made to prick out the seedlings when in growth. This is the stumbling block which has brought about the downfall of many an amateur's hopes. If sown in pots the seedlings should be left undisturbed for two seasons. Grown under a frame and sown thinly, four years may be allowed to elapse before the bulbs are transplanted. When the pots are shaken out, the little *Tulip* bulbs will be found near the bottom, while in frames many will be found a foot below the surface. They must be replanted in rich soil, but without fresh manure, and it is advisable to bed each bulb on a little clean silver sand. *Tulips* usually flower in from five to six years from seed. The raising of *Crocus* species should follow the same routine.

The *Gladiolus* grows more rapidly from seed, which is better sown under lights than in pots. Given good soil and thin sowing—they should not be transplanted—many of the *primulinus* hybrids, if sown immediately the seed is ripe, will flower the following season. All *Gladioli* should flower the second season from seed. All things considered, there are few more interesting border plants to raise from seed than the *Gladiolus*.

By many gardeners, unfortunately, the *Lily* family is looked on with suspicion as a race apart. To endeavour to raise *Lilies* from seed would be to some mere folly, and yet the best *Lily* bulbs procurable have been raised from seed; moreover, they are quicker to flower than *Tulips* and infinitely quicker than *Narcissi*. *Lilium Thunbergianum* and *L. philippinense formosum*, for example, may readily be flowered the second year, and *L. candidum*, *L. regale*, *L. pardalinum*, *L. Martagon* and other good garden *Lilies* should all flower in the third and fourth season. Trade growers usually sow the seed thinly

PRUNING AND THINNING FLOWERING TREES AND SHRUBS

on deep beds of rich but clean soil in a layer of sharp silver sand and leave them there until they flower. The reason for this is that the young bulbs scarcely become entirely dormant, or, if they do, do not ripen off together, so that removal causes serious damage, probably loss and certainly delay.

Closely related to the Lilies are the Fritillarias, also quite easily raised from seed. No one probably will wish to raise the Crown Imperial from seed—indeed, as a rule it does not seed very freely—but the Snake's-head, *Fritillaria Meleagris*, and related species are prolific seed bearers, germinate well, and may even be transplanted successfully when in growth (similarly to Onions); but this is wasted labour and not advised. Other uncommon bulbs may, of course, be raised and present no special difficulty if shade-loving species are given shade and those which need summer baking have it provided for them. In the former

THE REMARKABLE PRIMULA LITTONIANA.

class must be placed the delightful Dog's Tooth Violets (*Erythronium*), which in a shady frame, come readily from seed and usually flower the second year.

The hardy Primulas represent a race of which the easiest method of increase is certainly by seed, but they should be sown immediately the seed is ripe. Germination is then, in the majority of cases, very good and even and almost immediate. The young plants should be protected from too much sunlight, and when dry weather prevails a sharp look-out must be kept for aphid and red spider. Prevention is better than cure, and a good preventive when the plants are tiny is to flood the pan to the brim with soapy water occasionally. For this to be effective the pans must not be filled very full previous to sowing. As the plantlets become bigger the undersides of the leaves may be reached with an angle-jointed sprayer. If hardy Primulas sown as soon after ripening as seed could be procured do not germinate before winter, either expose the pans to a snowfall or cover them deeply with collected snow.

THE pruning of trees and shrubs is an art that requires judicious care and a considerable knowledge of the plants in question on the part of the pruner.

All pruning should be done with a view to flowering the following year, so that there may be no lack of blossom annually. Some people allow their flowering trees to grow as they like for a number of years until they get too large for their positions and then severely lop them after flowering, possibly with the idea that they should not require further pruning for some years to come. This is false economy, for besides making the trees look hideous for two years or more, only a few stray trusses of bloom can be obtained during that period; the young growths are far too crowded, and aphides play havoc with the wealth of young and tender leaves. This too often applies to Hawthorns, Laburnums, *Pyrus floribunda* and Cherries. Another barbarous method of pruning is the indiscriminate use of the garden shears upon flowering shrubs, clipping them into dumpy bushes in spring even before they come into bloom or should do. Such shrubs as Flowering Currants, Lilacs, Syringas and Deutzias can only give a truss of bloom here and there, where the shears have missed cutting the base of the flowering shoots clean away. Happily, most people who love shrubs know that this is wrong, but it is sometimes perpetrated in gardens under public authorities.

THINNING BY WAY OF PRUNING.

Summer pruning, where it is required, could well be placed under the heading of thinning, and it applies to those shrubs which flower in spring upon the old wood, or in summer on short lateral shoots from the old wood. Those that flower early on last year's growth would include *Spiræa Thunbergii*, *S. Veitchii*, *S. arguta* (often named *S. a. multiflora*), *S. Van Houttei*, *S. hypericifolia* and *S. prunifolia flore pleno*. These sometimes get rather crowded, and this may be rectified by cutting out a sufficient number of the oldest stems to make room for those bearing vigorous young shoots, retaining all strong growths of this year unshortened, even if that necessitates the removal of a considerable number of the older and weaker ones. The thinning should not be overdone, but calculation made as to how the bush is likely to fill up. Of the above, *S. arguta* and *S. Van Houttei* are the most likely to require thinning.

It is surprising how little pruning certain trees require if planted in places where they can be allowed to assume something like their natural size, whether they are grown upon low or tall stems. This little pruning or trimming they require should be given annually and not at long intervals. Hawthorns, Laburnums, Caragana, *Pyrus floribunda*, *P. f. atrosanguinea*, *P. f. purpurea*, *P. spectabilis* and the Judas Tree (*Cercis Siliquastrum*) naturally form round-headed trees, and if the shoots are allowed to grow full length they gradually produce spurs all along their length and flower profusely every year. Hard pruning will never encourage increased bloom, but hinders it by the production of strong young wood. Low branches may be removed until the head gets high enough to avoid inconvenience in the garden. Straggling branches may be shortened to maintain the round shape of the head. They seldom grow so dense as to require thinning, unless they have previously been lopped. Twiggy growths with plenty of spurs give the most blossom. If an occasional thick branch

has to be removed, the wound should be well tarred to keep out the spores of fungi. Especially is this the case with the Judas Tree, which is very liable to the coral-spot fungus. When this appears the diseased branches should be cut back to healthy wood and the wounds well tarred. *Laburnum Vossii* is a weak grower, compared with the others, and grows rather erect. It is therefore useless to prune it with the idea of making a round-headed tree. A better plan is to plant it where a broad-headed tree would be inadmissible.

As regards Almonds, Cherries, *Prunus cerasifera*, *Pissardi*, Bird Cherries, *Prunus subhirtella*, *P. Mahaleb* and all stone-fruited trees generally, the less pruning the better, and this may be done annually in winter or summer by cutting back straggling shoots and removing other undesirable ones. To shorten all the young shoots with the idea of keeping the tree small would be cutting away most of the flowering wood. The vigour of young trees may be restrained by root pruning them occasionally in October. Hard pruning and lopping are productive of gumming and other diseases. Even in confined spaces they should be planted where they could grow 12ft. to 15ft. high at least, without inconvenience.

Catalpas are peculiar in the manner of their growth. The leaves are either opposite or in threes, and no terminal bud is produced. To develop a shapely specimen from a small tree, a strong shoot should be trained upright to form a leader, till a trunk has grown 8ft. to 10ft. high, when the tree can be allowed to grow as it likes. Two or three buds at the end of each branch will give rise to as many shoots, forming a round-headed tree naturally. The side branches below the intended head can be removed, a few at a time every year or two, as the tree progresses.

SPECIES THAT REQUIRE CONSIDERABLE THINNING.

Certain strong growing shrubs that flower during June and July require a considerable amount of thinning, on account of the great number of thin and mostly useless shoots which they produce, and which tend to overcrowd the bushes, thus reducing the number of flowers and their size. The stronger growing species of Syringa (*Philadelphus*), including *P. coronarius*, *P. Gordonianus*, *P. grandiflorus*, *P. latifolius* and *P. Satsumi*, are particularly liable to crowding. *Deutzia scabra* (*P. crenata*) and its varieties, Lilacs, Snowball Tree, Guelder Rose, *Kerria japonica flore pleno*, Weigelas and the Japanese Quince (*Cydonia japonica*) may also be put into this category. The thin and useless twiggy branches should be cut back to the base, and if objection is taken to the height of the tall Syringas and Lilacs, the longer stems may be cut well back, always bearing in mind that plenty of this year's growing shoots should be retained unshortened, otherwise there will be no flowers next year. They require all their time now to grow and set the flower buds by autumn. The Lilacs could have been thinned to advantage immediately they finished flowering. The Weigelas do not grow so tall and need only have the flowered shoots cut back. Thin out old stems of *Kerria*. *Cydonia japonica* is best thinned in summer. Trees on walls may be spur-pruned in winter, or the side shoots shortened to joints, when they cease growing, and further shortened to rim in winter. The common *Hydrangea hortensis* and its varieties should have the flowering shoots cut well back to a good bud after the flowers fade, and this will answer the purpose of thinning. The flowerless shoots must

not be cut in any way. *Cytisus purpureus* and *Philadelphus Lemoinei* renew themselves from the base every year, so it is only necessary to cut out the shoots that have flowered, preserving the young ones.

EVERGREEN SHRUBS AND TREES.

No systematic pruning is required by evergreen trees and shrubs, unless they are trained upon fences or walls. Dead shoots or branches should at any time be cut away. Straggling branches may here and there be produced, and one plant may grow into or overlap another, owing to close planting. Such offending shoots or branches should be cut back to make the bushes stand clear. This applies to *Berberis Darwinii*, *B. stenophylla*, *Cotoneaster microphylla*, *C. thymifolia*, *Choisya ternata*, *Faurustinus*, *Fiery Thorn*, *Rhododendrons*, all species of *Escallonia*, except *E. Philippiana*, *Ceanothus Veitchianus*, *Camellias*, *Magnolia grandiflora*, *M. g. exoniensis*, *Garryas*, *Olearias*, *Kalmias*, *Pieris*, *Andromedas*, *Arbutus*, *Pernettyas*, *Rosemary*, *Lavender* and shrubby *Veronicas*. After all space available on walls or fences has been covered by *Crataegus Pyracantha* and *C. P. Lalandei*, the summer shoots that extend away from the wall can be shortened back in August or earlier, if growth is completed. The twiggy growths and spurs may be allowed to extend several inches away from the wall, because this favours flowering and fruiting. When *Rhododendrons* are beginning to get too tall for their position, it is a good plan to layer the lower branches to get young plant. The old plants will break again if cut down in early March. Hardy Heaths, like *Erica vagans*, *Calluna vulgaris* and their varieties, may have their flowering shoots cut back, nearly to the extent of the current year's wood in autumn; *E. carnea* late in April. No *Daphnes* require pruning, beyond regulating straggling branches.

NO PRUNING AT PRESENT

Quite a number of shrubs flower on the current year's growth, and can be pruned more or less hard, late in winter, or early in spring. These are now flowering or will bloom later, and should not be interfered with at present. They include all deciduous species of *Ceanothus*, all hardy *Buddleias*, except *B. globosa*, *Hydrangea paniculata*, *Spiraea japonica* (including all forms of it grown in gardens or catalogued under such names as *S. callosa*, *S. Fortunei*, *S. Bunnalda* and *S. Anthony Watereri*), *S. Douglasii*, *S. salicifolia*, *S. tomentosa*, *S. Menziesii*, *S. Lindleyana* and *S. Arctifolia*.

It is well to remember that such tall, sun-loving things as *Elaeagnus*, *Syringas* and *Snowball Tree*, on the north side of walls or fences, will not bloom well, if at all, if cut below the level of the same. They should be allowed to have full exposure to sun and air.

The proper pruning of flowering trees and shrubs is very important, and should certainly not be neglected. Far more shrubs, however, fail to flower through barbarous cutting than from want of pruning. Better by far leave shrubs unpruned than let the average jobbing gardener prune them.

HOKRIANUS.

THE PERENNIAL LARKSPUR

FEW flowers have been more greatly improved of recent years than the Delphinium. Further great improvements may safely be predicted, but the plant as we know it to-day is among the most useful in the garden. An alteration or development of a flower is not always an improvement. The round petalled form which the florists

when we approach the fuller colourings. Many people find the white-centred cobalt blue sorts "spotty" in appearance, especially in mass planting. They pin their faith to shades of deep purple, violet and indigo with bee-like centres. In the writer's opinion this spottiness represents tradition rather than observation. Certainly these white-centred forms are very beautiful for

THE OLD BUT BEAUTIFUL DELPHINIUM BELLADONNA.

insist on in the perfect Tulip has lost much of the charm of the flower with more pointed petals. This, in the half-expanded state we all appreciate in the Rose, has a far more graceful outline. In the case of the Delphinium, however, development is, at any rate for the present, taking place along the right lines. The Larkspur is essentially a stately flower. Let us therefore seek to breed into our seedlings all the graceful stateliness and stately graciousness of which the flower is capable. Since grace is an objective, forms with stub-ended-overcrowded spikes should be eliminated as quickly as possible and replaced by others seemingly modelled on a good example of an English church spire. The tapering cones should have flowers of sufficient substance to withstand ordinary English weather, and they should not be overcrowded. The ungraceful Dutch Hyacinth effect is emphatically not wanted in the Delphinium. Many single Delphiniums are wonderfully beautiful, but their glory is apt to be transient compared with the semi-double forms, so that it is this latter class for which it is best worth striving.

So far agreement will in all probability be general, but when one comes to discuss the question of colouring, tastes will be found to differ widely. It will, however, probably be fairly generally agreed that there is room for more really good azure blue varieties. The raisers are probably all alive to this, but varieties in this colour are not easy to produce with the stately spire so much admired. The clear pale blues are also much appreciated; differences of opinion come mainly

cut flower. Many critical spirits dislike the combinations of colour found in each blossom of many Delphiniums. The admixture of true blue, purple, mauve and rose in some varieties is certainly extraordinary, but the *tout ensemble* is almost invariably pleasing. There should be room in gardens of any size for almost every shade found in Delphiniums except white, which the writer, at any rate, could well do without. These "white" varieties are for the most part the colour of unblued distemper, but *Morheini* is quite decently white until there comes a shower of rain, when the underlying blue comes out as a dingy lilac tinge.

Like the mixed colours in the individual flowers, a mixed bed of seedlings will get on fairly well together, but segregate the blues from the purples, propagate them and arrange them in colonies, which is, after all, the most delightful way of growing Delphiniums, and if a colony of azure ones strikes the line of vision near a rosy purple clump, they will cry aloud to be separated.

The Delphinium, if it is to attain perfection, must have a rich deep soil, which must be well cultivated in summer. Clumps should be divided every third year. Of its value for massing in the herbaceous border there is no need to speak, but it is perhaps not sufficiently appreciated how effective strong "colonies" are in a shrubbery border nor what an acquisition they are in that favourite part of the demesne—the wild garden. If the plants are well fed they will grow away quickly when the first spikes are removed and

flower again freely in autumn. Some of the newer varieties, indeed, form a multitude of long, elegant side spikes which greatly prolong the flowering season. The principal enemies of this invaluable plant are slugs, which by persistently gnawing on the incipient shoots in early spring weaken and even destroy it; rabbits, which are "impossible" visitors to the garden; sparrows, tits and finches, which sometimes peck the tender growths to pieces; and, above all, mildew. Delphiniums, unlike Roses, do not seem to vary greatly in their susceptibility to this hideous disease, except that old and over-propagated varieties are more subject than newer and more robust ones. Good cultivation, which will maintain the constitution of the plants and prevent

the inequalities of moisture at the roots which predispose to disease, and an avoidance of draughty corners when planting are the best preventives. Flowers of sulphur dusted on or liver of sulphur sprayed on—care being taken with either specific to cover the undersides of the leaves—are the most effective remedies. To be effective they must be used immediately the fungus shows itself.

Lists of varieties in a flower which progresses so fast seem a little futile, but of those now in commerce the best tall varieties are perhaps Millicent Blackmore, Statuaire Ruble, King of Delphiniums, The Alake, Mrs. Creighton, Queen Wilhelmina, Rev. Lascelles and Lizzie van Veen. Of the more leathery varieties of middle height, Belladonna, Belladonna semi plena, Fanny

Stormonth, Capri, Mrs. Thompson and Lamartine are excellent; while for the front of the border the beautiful deep azure species tatsienense is first rate. The red-flowered species nudicaule and cardinale and the sulphur Zulu are another story. Effective tall herbaceous plants are not over-numerous, so that it is new spiry varieties which are most wanted. Mr. Watkin E. Samuel of Wrexham is specialising in these, and in some of his new varieties, five of which have recently received the award of merit of the Royal Horticultural Society, the flowering spike is quite pit. long, carried on stems of almost incredible height and stoutness. Such plants as these will make their presence felt in the back of the herbaceous border.

LUPINS AT CATOR COURT, DEVON

THE rather meaningless jumble of geometrical or merely shapeless beds in which years ago one often saw hardy perennial plants displayed has given way, under the influence of improving taste in matters horticultural and the wave of fashion which almost always follows improvements of this kind, to the simple herbaceous border or, more usually, the straight walk bounded by herbaceous borders on either hand. Such borders admit of much variety in arrangement, since the whole border may be carried out in shades of blue or pink, for instance, or certain colours may be made dominant in particular sections of the border and the whole scheme made subordinate to them.

This is not the time or place to discuss the arrangement of such borders. They are mentioned only to point out that the long formal border is not the only way in which hardy perennials may fittingly be displayed. The massing of Rhododendrons and other flowering shrubs so as to define turf vistas, often contoured, is a recognised part of present-day garden design, and such treatment is becoming appreciated by a wider circle year by year. This style of planting is, however, still unusual as applied entirely to herbaceous plants. How effective it may be the accompanying pictures and a little imagination as to colouring will shew.

Such planting, skilfully carried out, displays to the full the natural grace and individuality of the plant, while making an added appeal because it shews it under conditions approximating to those in which one would imagine it growing wild. It is not every house, of course, of which the architecture would admit so informal a treatment close to it, but where parterres or formal beds and borders are called for in the immediate surround, space can usually be found for more natural planting a little further afield. If the ground at disposal falls from either side to, it may be, a trickle of water, or, failing this, if it has a slope and a setting of trees—there is nothing much more beautiful than an old Apple tree—so much the better.

Considerations of space will insist that some of us grow our Lupins and Delphiniums, our Irises, Peonies and Poppies in formal borders. The more need, then, that those who may, should grow these plants under more natural conditions where their individuality may be better appreciated.

There are many gardeners who take a legitimate pride in growing successfully rare and difficult plants, but it must be confessed that, where decorative effect is the object sought, those plants should be looked for which flourish with the least

A BEAUTIFUL GROUPING.

DRIFTS OF LUPIN AND SINGLE ROCKET.

A FINE STRETCH.

CLOSER INSPECTION SHOWS THE INDIVIDUALITY OF THE FLOWER.

possible attention and which seasons drier or wetter than the normal do not seriously affect. To this easiness of culture add the capacity to provide broad effects, and it will be easy to see why at Cator Court, which, on the fringe of the moorland, stands 1,100ft. above sea level, Lupins have been selected for early summer effect. With these is associated, as will be seen in some of the pictures, the single white Rocket, which has a pleasing Stock-like fragrance. Irises of all kinds, but mainly Bearded sorts, are also grown, as well as Paeonies. Later, Oriental Poppies make a gallant show, followed by Hollyhocks, Delphiniums and Sweet Williams, which in their turn give way to herbaceous Phloxes and Michaelmas Daisies.

Practically all the Lupins seen in the pictures originated from two packets of seed, one of *Lupinus polyphyllus* and the other of *L. polyphyllus* x *L. arboreus* hybrids. Their increase is of the simplest, either from seed, which may be sown outdoors either in spring or summer (as soon as ripe), or by division in autumn.

The immense range of colouring now to be found in herbaceous Lupins seems not fully to be realised. Too many people still think of this flower in terms of the rather dingy white and dowdy purple generally seen five and twenty years ago, with the possible addition of one of the first-introduced pink forms, of which the flowers, as they passed their best, deepened in colour and took on an ugly purplish tinge more to the taste of carrion flies than human beings.

To-day the colour range is truly marvellous, and if the purpling of the passed flowers of the pink sorts has not entirely been abolished, it has at any rate been mitigated. From deep violet-purple through a multitude of tones of mauve and lavender and from an almost pure deep blue through brilliant almost "electric" shades we reach a good clean white. These ranges of colour may be traced in flowers which for practical purposes may be called self-coloured, but in addition there are innumerable forms in which the standard is of some shade of blue or purple and the wings of a shade of yellow or clear white.

Downer's Delight is a strikingly coloured form with more than a hint of brick-red in the combination. It is the only Lupin which has a tendency to be "quarrelsome," not only with other plants, but with its own kindred. Leaving this variety aside, however, there are several shades of an almost true pink and numbers of yellow-pinks giving warm buff and apricot tones. Few flowers have such a colour range as this.

Much of the diversity of colouring has unquestionably been obtained by crossing the herbaceous (*polyphyllus*) forms with the fragrant Tree Lupins (*Lupinus arboreus*), and it is pleasant to record that many present-day varieties which in habit of growth shew no trace of *arboreus* parentage have retained, at least to some extent, its delightful fragrance.

At Cator Court seeds of the Lupins and Rockets are sown in drills in a nursery garden in April, pricked out in rows a foot apart and transferred to their permanent situations in autumn. The Delphiniums are raised in boxes under glass and subsequently transferred to the nursery. The Bearded Irises are divided and replanted after flowering, and the Phloxes are divided in late autumn. Phloxes may, of course, be readily increased from cuttings in spring.

The soil is admirable for propagating and also excellent for growing plants suitable for division, being a light peaty loam. It never cakes, and retains winter moisture excellently. Hoeing, therefore, presents no difficulties, which is fortunate, as weeds spring up in battalions in such congenial soil.

A BEAUTIFUL CHERRY

BY GERTRUDE JEKYLL, V.M.H.

THE genus *Prunus* provides us with a large number of flowering trees and shrubs, for the same generic name includes not only Plum and Cherry, but also Peach, Apricot, Almond and Laurel, besides our native Blackthorn, Gean and Bird Cherry. Several species belong to

25ft. In the case of the specimen shown in the illustration, which is growing in Miss Mellersh's garden at Holloway Hill House, close to Godalming, it has been trained horizontally with a circumference of 75ft. Among the numbers of beautiful Cherries and Plums in cultivation, this is one of the earliest to bloom.

A FLAT-TRAINED SPECIMEN OF THE ROSEBUD CHERRY.

Asia Minor and a number come from China and Japan, the last being the home of *Prunus pendula*, where it becomes a good-sized tree, though in England it stops at a height of 20 ft. to

It is a precious thing in March and early April, brightening the garden before deciduous trees are in leaf. It has the pretty popular name of Rosebud Cherry.

HERBACEOUS CALCEOLARIAS

IN common with the *Cineraria*, these share an unenviable reputation as "dirty" plants, and it is no use attempting to disguise the fact that they are especially liable to attack by aphides or green fly. He who would grow them successfully must be prepared to fight these unceasingly from start to finish and then they are one of the easiest and most gorgeous of all greenhouse flowers, to say nothing of their economy in heat. Indeed, it is just here that we come to the root cause of a great deal of the trouble; no single degree of heat should ever be used that can be avoided, and where kept under the coolest possible conditions all the while, it will be found that green fly is far less troublesome and the result in every way superior. The finest and healthiest lot of plants I ever saw were grown in an old ash pit, converted into a small greenhouse by placing some old frame lights over the top so as to form a span roof. The floor was the natural earth and an entrance had been made at one end with a rough door made from an old orange box. There was no method of heating the place and—beyond standing the plants on the floor and covering them with newspaper and throwing old table cloths or rugs over the roof during the severe cold—the plants were quite unprotected against the sharpest frosts. Further than this, the house had a north aspect and was shaded from all sun by an old garden wall. Here, in May and June, one could always see a gorgeous display of tigered selfs and spotted flowers on giant plants, the pale green wrinkled foliage of which was a pleasure to behold—plants

that would have done credit to Chelsea itself or any other great flower show.

Seed should be sown now. Development is very slow in the early stages and the foundation of a large plant—2½ ft. to 3 ft. across—is laid in early sowing and steady continuous development until flowering time arrives. Seeds are extremely minute; they are the most difficult of any to distribute thinly and evenly, and a finely sifted compost is essential. Two parts of loam to one of fine sand, perfectly mixed together, is suitable, sifting this through a fine meshed sieve and placing the rougher part that will not pass through at the bottom of the pan or box in which the seed is to be sown. Fill in the remainder of the space to within a quarter of an inch of the rim with the finer soil, making this quite level, and finish by watering through a fine-rosed can. After leaving for an hour for the superfluous moisture to drain away, everything is ready for sowing. The packet should be opened with care, inside a greenhouse or shed, so as to be secure from sudden puffs of wind. The seed is usually contained in a small inner envelope and should be mixed with an equal bulk of the finest silver sand, such as is used by housewives for scouring purposes, as this facilitates thin and even sowing. Simply scatter it on the surface and do not attempt to cover in any way with soil. A pane of glass should be laid on top and the pan stood in a cold frame where the sun cannot reach it, for a very brief exposure to this is sufficient to end their existence. Water will not be required for some time, but immediately the

surface shows signs of drying, the pan should be immersed to half its depth in tepid water until this has percolated right through to the surface, then take out and drain and replace in the cold frame again.

When signs of germination are observed, and it takes keen sight to note this in its earliest stages, the pane of glass which covers them should be tilted at one corner with a small piece of wood so as to allow some air to reach them; gradually withdraw this as the young plants gain size and strength. Keep them moist and cool until they are large enough to handle easily before transplanting. This is a delicate matter, as the plants are extremely brittle and the greatest care is necessary in handling them or they will die off wholesale. I usually prick them into boxes first—about 3 ins. apart—and grow them on in these for a few weeks until the leaves are nearly touching, and then they are transferred to single pots.

A compost of two parts fibrous loam, well pulled to pieces, to one of old rotted manure, with sufficient sharp silver sand to make the whole porous, is ideal, and while pressing this down firmly, take care not to make it too solid or the thin fibrous roots cannot work easily among it. Replace them in the frame where they should be kept as far into the autumn as possible, consistent with security from really sharp frost. The base of the frame on which the plants are stood should consist of a bed of ashes 6 ins. thick; this not only prevents the ingress of worms, but assists in maintaining the cool and humid conditions so favourable to healthy growth. Overhead sprinklings, through a fine-rosed can, should be given each afternoon when closing the frames for the night. Considerable trouble will be avoided if an insecticide is mixed with this occasionally, though insect pests are not usually troublesome until the plants are in the greenhouse. Every scrap of decaying foliage must be removed, and especially as the autumn comes on, or they are apt to set up decay at the collar and lead to loss of the plant.

Good specimens in autumn should be in the form of rosettes of healthy dark green foliage, without the least signs of drawing or a speck of green fly. The removal to a greenhouse must be effected unless the frame in which they are growing is furnished with hot water pipes, into which the circulation from the boiler can be turned as required, but they should only be taken indoors when sharp weather threatens. These are ideal conditions and most growers have to house them among a miscellaneous collection of other plants. In any case, give them a good light position on a staging covered with shingle or ashes and well away from the hot-water pipes. As a maximum, 45° of heat should not be exceeded, while the plants must have plenty of water. Early in the year, when signs of renewed growth become apparent, the plants should be given a shift into the flowering size. Five-inch pots are large enough for most plants, the most vigorous specimens going into the 6-inch size. Use similar compost to that recommended previously and drain the pots freely, watering carefully until these are well filled again with roots. As the flower stems commence to push up, thin green pointed stakes should be inserted, sloping these outwards so that the heads will have space to develop fully without crowding. Tying must be carefully done; the flower stems are quite as brittle as the foliage and it is very easy to snap them.

From this time onwards watering should be given regularly with weak liquid manure of varied character, this being a great assistance to the production of large flowers, but it must be really weak, especially in the case of all chemicals. Constant vigilance must be exercised all the time they are in the greenhouse for the appearance of green fly,

and directly the first one is noticed, fumigate lightly, following this up a few days later if any live insects can be found. Shade must be afforded the opening flowers on all days when the sun is bright. No plants so quickly

show foliage disfigured by exposure to sunlight as these, more especially if at all dry, and every care must be exercised to keep them uniformly moist and well shaded whenever the sun is bright.

CROYDONIA.

A NEW PEST OF STRAWBERRIES

BY HERBERT W. MILES, N.D.A., DIP. AGR. HONS. (HARPER-ADAMS).

FROM time to time "white grubs" are reported as doing serious damage to Strawberries, and they are generally understood to be the larvæ of the cockchafer (*Melolontha vulgaris*, L.) and those of the garden-chafer (*Rhizotrogus solstitialis*, Fabr.). So far, however, no case has come to the writer's notice of any species of *Geotrupes* being recorded as culprits in this connexion. During the winter and spring of 1921-22 numerous instances of serious injury to Strawberry plants by white grubs were observed at the University of Bristol Agricultural and Horticultural Research Station, Long Ashton. Some of these white grubs were collected and kept under observation in the laboratory, with the result that, when the adults emerged, they proved to be the Common "Dor" or dung beetle, *Geotrupes spiniger*, Marsh.

The larvæ are thick, fleshy grubs, whitish in colour and much swollen and distended towards the tail end. Owing to the contents of the alimentary canal being partially visible through the outer layers, a faintly bluish coloration is imparted to the hind portion of the grub. There are three pairs of light brown or straw coloured jointed legs, and of these the posterior pair are much reduced, being only about one-third of the length of the intermediate and anterior pairs. The head, which can be partly withdrawn into the first thoracic segment, is brown and provided with very strong dark brown biting jaws. Mature specimens measure from 1½ ins. to 1¾ ins. in length. When unearthed the grubs are seen to be in a sharply curved position somewhat in the form of a narrow U, the lower surface of the thorax resting on the under surface of the last few abdominal segments, which are broad and flat.

The pupa is a stout whitish and fleshy body. It is covered with a thin membranous coat, through which the outlines of the limbs can be seen. It is located inside a strongly constructed earthen cocoon. The pupal stage is about ten weeks in duration.

The adult (see figure) is a typical dung beetle. It is bluish black in colour with the upper surface quite free from scales or pubescence, and the lower surface studded with stoutish bristles which, in the last four abdominal segments, are more thickly massed at the sides than in the centre. The under surface is a rich metallic violet blue colour. The thorax is comparatively smooth on the disc, but is finely punctured towards the sides. Near the lateral edges of the thorax there are two distinct depressions. The elytra are shallowly striated and very rounded at the apex. The legs

are much toothed; they have numerous spines and bristles and are typically fossorial.

Where the grubs were feeding at the roots of Strawberries the main roots had been severed either partially or completely, and the stocks had been damaged by the gnawing of the insect. In severe cases the plants had been utterly destroyed.

LIFE HISTORY.

In the usually accepted accounts of the life history it is stated that the female tunnels below dung and taking down certain portions of it masses them together, and in the ball thus constructed lays an egg, from which the larva emerges

ADULT DUNG BEETLES AND PUPATION "NESTS."

in about eight days. The grub then feeds on the prepared food, which is supposed to be enough to satisfy its larval requirements.

The presence of larvæ in Strawberry beds may possibly be accounted for, where farmyard manure has been torked in during the winter, by supposing that this attracts the female for egg-laying. If only a small amount of the manure is left undecayed it might prove insufficient for the larvæ, which, after exhausting their stock of food, proceed to move about in the soil and feed on the roots of any plants with which they may come into contact or on any available vegetable matter. An alternative explanation is that the food supply prepared by the female is normally insufficient, and that the larva lives, for a shorter or longer period, on other organic matter in the soil. This, however, is a point which can only be elucidated by the careful observation of controlled life-cycles.

In cases where the larvæ are feeding at the roots of plants their development may be much slower than when feeding in dung and, like the chafer grubs, they may spend about two years in the larval stage. When fully fed the larva is very restless and moves round in the soil until a fairly even cavity is formed. It then proceeds to pass soil through its body. This

soil is voided as a soft mortar-like mass and is pressed against the side of the cavity by the upper surface of the caudal portion of the larva until it sets hard, when the grub detaches itself and proceeds to line the adjoining areas. Finally the whole cavity is lined, forming an even cell in which, after a short time, pupation takes place. In the accompanying figure such cells are seen; the left-hand one measured 1½ ins. in depth, while the right-hand one was 1 in. deep and ½ in. across the exit hole. In captivity the pupal stage lasted about ten weeks, the adults emerging towards the end of April.

Very little is known regarding the length of life of the insect, however; a French writer, Labitte, in a paper on "The Longevity of Certain Insects in Captivity" (*Abst. R.A.E., Series A, Vol. V, page 20*), gives the total life of an allied species, *Geotrupes stercorarius*, as occupying 1,137 days, *i.e.*, three years and six weeks.

NATURAL ENEMIES AND CONTROL MEASURES.

In common with other white grubs, the larva of *G. spiniger* is probably subject to the attacks of rooks, jackdaws and seagulls, while Collinge records the nightjar as destroying the adult beetles.

Apart from destroying the adults whenever they are seen crawling near Strawberry beds, control will probably take the form of good cultivation in spring and lifting and replacing sickly or injured plants. Where the nature of the injury indicates the possible presence of root-eating grubs, the surrounding soil should be examined and any larvæ destroyed. This is an expensive and laborious method when employed over large areas, but is quite practicable in small beds and, in the present stage of our knowledge of soil insecticides, is the only treatment which can safely be recommended.

ERICA CINEREA AT MIDSUMMER

THE first of our native Heaths to bloom (though *E. Tetralix* may run it very closely on some moors), the common "Bell Heather" holds a place of no little importance in cultivation, for it comes into flower in early summer, that is, before the other principal groups—*ciliaris*, *vagans* and *Calluna vulgaris*—are showing any colour.

Though never a tall grower, cultivated varieties of *E. cinerea* may now be roughly divided into two sets, the one being normal in height and the other quite dwarf and very compact. Among the former the first to flower (early June) and the best for extensive planting is *E. c. rosea*, a lovely form with soft rose coloured flowers in which the bluish tint often seen in the wild plant is entirely absent. Another first-rate variety is *E. c. spicata*, which has longer sprays (6 ins.) of red-purple blossoms, not quite so taking in colour as the preceding.

The white varieties of *E. cinerea* are not a success with us, having the same fault as *E. carnea alba*, *viz.*, shyness of blooming, but the dwarf white is, if anything, better than the taller one. Among the coloured forms of the lesser *E. cinerea* are several excellent varieties, foremost among which is *E. c. coccinea*. This is quite a low, close-habited little plant, but it is one of the earliest to come into flower, and its freely-produced blossoms are an intense crimson-scarlet that at once distinguishes it from any other hardy Heath. *E. c. atrosanguinea*, the deeply bronzed foliage of which breaks into a fine ruby crimson about Midsummer Day, is, perhaps, the next best of this class, and *atropurpurea*, with rather a more purple hue, is another well worth a place.

All of these are quite at home on our dry, loamy, sun-beaten banks, and once established they will "carry-on" for many years, increasing in beauty as they grow older.

N. WALES.

CORRESPONDENCE

SILVER-LEAF DISEASE

I READ in your excellent paper last autumn the detailed account of how someone had absolutely cured a Peach tree under glass badly diseased with silver-leaf by the application of doses of soot and water at certain periods during autumn, winter and spring. This good news seemed to me to be on the lines of the Gospel—Mr. Jacob please note—really too good to be true, because a friend who has written much on kindred topics has assured me most positively that *silver-leaf is absolutely incurable*, adding, however, a proviso that if a tree does get cured it is not true silver-leaf. Sort of mental reservation?

Well, to proceed. Having five Plum trees in my garden affected with silver-leaf, two very badly, I thought it was at least worth while to give the thing a trial; so I studied again the article in THE GARDEN and found you had to mix soot in a bucket with water till it was a paste—a nasty job. No, thank you! So I put a shovelful of soot round each of the affected trees, forked it over and watered it twice. This my gardener and I did from last autumn to the present time about five times.

Great was my interest this spring to see the leaves of the Plum trees; but I have waited till the leaves are now well out and expanded, and write to say that we cannot find a trace of silver-leaf on any of the five trees. They are all in excellent condition, no extra growth, and two are bearing a heavy crop of Plums. Of course, it remains to be seen whether the silver-leaf will return.

I have been thinking the matter over, however, and have come to this conclusion, that there must

be in soot, besides sulphate of ammonia, some fungicide which the trees take up with the stimulant. I wonder if any reader can give us the

A SMALL GARDEN. THE TENNIS-COURT SURROUND.

chemical analysis of soot? I am also very strongly inclined to think that a similar treatment to Apple trees suffering from canker would cure them. Well, of course, everyone will be agreed who did not see my trees that they never had silver-leaf at all—at least, not the real thing—and I really expect that hardly any other reader of your paper with trees suffering from silver-leaf tried the remedy, because it seemed too good to be true.—W. E. M. CORELAND.

MAKING A SMALL GARDEN.

SOME time ago a suggestion was made in THE GARDEN that photographs and descriptions of small new gardens might be interesting to its readers, as a contrast to the beautiful old large gardens so often illustrated.

Twelve years ago this Somerset garden was a bare windswept field of less than an acre, surrounded by a low ragged hedge and containing nothing but four Walnut trees planted in a straight row. Here and there some Llus in adjoining fields could be seen above the hedge. It is an amateur's garden. The owners, who were quite inexperienced, planned it themselves and laid it out by degrees, and for the first nine

years had no resident skilled gardener. Three years ago the owner of a pair of skilled hands and a good brain, who had already done much to help and advise, began to give all his time to the garden, and was joined at the same time by another (trained) gardener, so that latterly

the little place has had every care and attention.

The first two or three years passed in a long struggle against drought and winds, which took a heavy toll of young newly-planted shrubs and trees. It was difficult to encourage even Laurels to grow sufficiently to provide a little shelter; then came the war and the enforced neglect of the flower garden, the little available labour being concentrated upon the fruit and vegetables. But now shrubs, such as *Choisya*, *Photinia*, *Viburnum Carlesii*, *Ceanothus* and *Azara microphylla*, flourish; a specimen of the latter against the terrace wall measures 20ft. in height.

A terrace walk leads to a rose pergola, which is continued by a lime walk, bounded on one side, in the shadow of the trees, by a spring garden, gay at that season with bulbous flowers and *Berberises*, and, when the Limes are in leaf, brightened by *Columbines* and, later, *St. John's Wort*. On the other side, between pillars of *Irish Yew*, the tennis lawn, sundial garden and shrub garden come successively into view. In front of the house a tiny formal garden surrounds an old pump.

The garden makers had one great asset, plenty of old stone for paths and borders; and one great drawback, so much of the soil was poor and full of stones. They hope these pictures may encourage others to create small gardens of their own, seeing the results which may be obtained in twelve years under most unfavourable conditions (in the war the flower garden and lawns became a jungle). These garden lovers are self-taught from books and papers, THE GARDEN being a faithful friend during the whole twelve years.—K. D. W.

THE DURATION OF HOLLYHOCKS

ARE single Hollyhocks long-lived plants? There is a beautiful single salmon-pink Hollyhock ten years old in this Highland garden. It is one of Dobie's seedlings, probably of Alleghany descent, as the flowers have trilled

IRISES IN THE SHRUB GARDEN.

edges. The plant, which, of course, has grown into a clump, has never been disturbed and has always flowered freely, throwing up four to six spikes every year and promises to do so again this summer.—E. B.

[Single Hollyhocks are more robust and often longer-lived than the double ones, but odd clumps of double Hollyhocks some years old are not uncommon. Few would care, however, to rely upon their longevity.—ED.]

A FINE DAVIDIA.

I HAPPENED to visit the garden of Mr. J. A. Christie, Framingham Manor, Norwich, on June 1, when his specimen tree of *Davidia lutea* was at its beauty. At a first glimpse from a few yards away the bracts look very much like numerous three-corner paper bags tied to the branches. The tree is 20ft. high and the circumference of its spread is 60ft. I think it must be as good a specimen as can be found anywhere in Eastern England.—H. PERRY.

IRISES AND WATER.

THE Iris family at last appear to be getting the attention they so richly deserve. Personally, I think wrong handling of this genus has had a lot to do with keeping it in the back ground. When one mentions *Iris Kämpferi* to people, one often gets the reply, "Ah, yes! I would love to grow them, but they must have water and I have no suitable position." I think the long drought last year should have knocked on the head the opinion that Irises must have water. While many plants that are certainly not looked upon as bog plants were absolute failures, *Iris Kämpferi*, with us, were never more beautiful. A patch of 5,000 plants in light gravel soil with roots practically touching gravel were a perfect picture just at the time when the drought was at its worst. One naturally looked for short stems and washy coloured flowers that would go over in a few hours, but they were just the reverse. Stems of some varieties were well over 3ft., and the blues and purples were simply gorgeous. Another batch of 3,000 planted in the dampest position we could find were very erratic. Certainly there were many good flowers, but in comparison to the large plot they were failures. Again this year we have the same result. The ones on light dry ground are smothered with buds, and coming away strong and even. At the present moment a pond near by is full of *Iris ochroleuca*, and although they are certainly beautiful a few stray plants through the place are equally good. How many people are denying themselves one of the most beautiful flowers because they are under the impression they must have water?—W. SLINGER, Newcastle, Co. Down.

A GLORIOUS GENTIAN.

THE interesting catalogue of Gentians given in THE GARDEN for June 17 (page 287) makes no mention of *Gentiana Farreri*. Perhaps all your readers have not seen the description of it by the late Reginald Farrer, whose name it bears. It was he who discovered the plant in the mountains of Northern China. The following quotation is taken from his book, "The Rainbow Bridge," written in the year 1920: "*Gentiana Farreri* . . . bids fair to be as solid a permanency as *G. Gentianella* itself. It is perfectly hardy and (what is very remarkable in any Gentian, but miraculously so in a Gentian so miraculously beautiful) it is perfectly vigorous and easy to deal with in any reasonable conditions of culture in a cool place, not parched or waterlogged. . . .

In addition to growing so freely and flowering so lavishly in so late and dull a moment of the year (August and September), this preposterously good-tempered exception to the rule of its race keeps its glory open, rain or shine, can be struck from cuttings as copiously as a *Viola* and layered along its shoots as complacently as any *Carnation*. . . . And its beauty! . . . I stood rapt in contemplation before the actual plant . . . well worth the whole two years' expedition merely to have seen it. . . . Every day in early September brings a fresh crashing explosion of colour. Each

where it succeeds, and some cultivators grow it splendidly.—ED.]

A RARE SHRUB.

I AM sending you a photograph of *Fabiana imbricata* growing in a stable yard in this county. The bush is about ten years old and is planted against a wall facing south. It receives no protection in winter.—SOMERSETSHIRE.

[Though of Heath-like appearance, *Fabiana imbricata* is not a member of the Order *Ericaceæ*, belonging, in fact, to the *Solanum* family. A native of Chile, this beautiful shrub succeeds outdoors only in the milder parts of Britain. Attempts to acclimatise it at Kew have not been successful, though it has occasionally survived a winter outdoors. From gardens with a suitable climate it ought on no account to be omitted.—ED.]

A FINE PLANT OF *FABIANA IMBRICATA*.

of the weakly stems concludes in one enormous upturned trumpet more gorgeous than anything attained by *G. Gentianella*, but in the same general style and form. But the outline is different with a more subtle swell to the calice, and that freaked outside in heavy lines of black purple that divide long vandykes of dim periwinkle blue with panels of nankeen buff between; inside, the tube and throat are white, but the mouth and the wide bold flanges are of so luminous and intense a light azure that one blossom of it will blaze out at you among the grass on the other side of the valley. . . . It is like a clear sky soon after sunrise, shrill and translucent as if it had a light inside. . . . It literally burns in the alpine turf like an electric jewel, an incandescent turquoise."—M. F.

[The writer of the article in question was careful to point out that the varieties mentioned were not exhaustive. He wrote only of the species he had successfully tried. *Gentiana Farreri* is certainly a good plant, though whether in cultivation it deserves the extravagant encomiums of the late Reginald Farrer is another matter. *Gentiana Kurroo* is another beautiful Gentian

THE ROTATION OF CROPS.

ON page 229 I made a remark that the "sowing or planting of a deep rooting crop after a shallow rooting one enables the plants to feed at different levels in the soil." This has been construed by W. H. Lodge (page 294) to mean that I am an advocate of shallow cultivation, whereas I have practised deep cultivation for more than forty years. I have had all sorts of soil to deal with in my time, from heavy soils of unknown depth to deep, light soils overlying sand, and a sandy soil averaging 6ins. deep, overlying coarse, water-worn flint gravel of unknown depth,

and managed to take good crops off all of them. In early days I had ample practice in trenching the soil 3ft. deep and manuring it at different levels. We made a point of trenching about a third of the available space for vegetables every year in October, so that in the course of three years we had trenched the whole of the vegetable garden ready to begin again the fourth year. This was done without respect to the length of the roots, whether Radishes or Parsnips. It does not strike me that Radishes or Potatoes could collect so much food from deep levels as Parsnips. I know all about the capillarity of the soil or sufficient to enable me to take advantage of it. Roots that actually come in contact with the soil are able to dissolve and appropriate plant foods that the water of capillarity could not carry up. The more soluble plant foods are liable to be carried deeper and deeper in the soil, finally passing away in the drainage. We never used the watering-pot outdoors, except for newly planted bedding plants, seeds, cuttings or newly transplanted evergreens in late spring. There was neither club-root nor finger-and-toe in the gardens so cultivated.—J. F.

GARDENING OF THE WEEK

FOR SOUTHERN GARDENS.

The Kitchen Garden.

Hoeing.—The hoe should be used constantly among all growing crops, such as Onions, Carrots and Beetroot, during dry spells. This will not only destroy small weeds, but will check evaporation. Moreover, the frequent movings of the soil creates a mulch, which in itself is equal to a good watering and often far more beneficial, unless the latter can be regularly kept up.

Vegetable Marrows.—During intense heat there is nothing more congenial and helpful to these plants than a thorough drenching with water of the roots and all the foliage late in the evening. By pinching a few of the leaders occasionally a quicker fruiting condition is brought about. Remove all fruits immediately they are of sufficient size for use.

Seeds.—Additional sowings of Endive, Lettuce, Radishes, etc., must be made in accordance with requirements. Should the ground be dry all drills should be well watered before sowing.

Dwarf Beans.—Make a further sowing of these on a well worked piece of ground, watering the drills first if necessary. It is sometimes convenient to make use of the borders from where early Potatoes have been lifted for this sowing.

The Flower Garden.

Rhododendrons and Azaleas that have finished flowering should have all dead blooms and seed-pods removed. The latter particularly so, as they make a big drain on the energy of the plants if allowed to remain, while the former look untidy if the plants are in a prominent position. Recently planted specimens must be well watered during dry spells, or growth will be unsatisfactory, for it must be remembered that these plants have no long roots to penetrate into the ground for moisture, but balls of fibres only. Where the plants are grown in beds and a good mulching can be given this will be of great help in conserving the necessary moisture round the plants. Short lawn mowings and partly decayed leaves will make a suitable mulch should no manure be available.

Roses having exhausted themselves of the first crop of blossom should have all dead flowers removed. At the same time a few of the weak growths should be removed. When this work is completed give all the plants a good watering with weak liquid manure so as to assist in the building up of good wood to produce the next lot of flowers.

The Hardy Fruit Garden.

Thinning Fruits.—It is obviously impossible to lay any hard set rules down about what crop of fruit shall be left on trees, whether it be Plums, Apricots or any other fruits. The health of the trees must be to a great extent a deciding factor. If trees are in good health it is fairly safe to make them carry a good crop, as oftentimes such a practice will correct a little of the grossness of growth. Trees in poor or only moderate health should be allowed to carry but few fruits, and the same should apply to young trees which are being trained to fill up allotted positions if there is any danger that much cropping would give them an unnecessary check.

Fruit Under Glass.

Strawberries for Forcing.—As soon as the runners are obtainable a start should be made, by whichever method is followed in securing the required stock. I know of no way which gives better results than by layering into small pots, which should be half plunged between the rows in hatches of such size as are suitable to meet the demand of available runners. These runners, which supply plants for early forcing, are much better when obtained from plants set out last season for this purpose; but where such a practice cannot be followed some of the more healthy and vigorous rows should be quickly cleared of fruits and the plants be given a few good soakings of diluted manure water, which will soon revive the energies of the plants and make the young plantlets full of activity.

H. TURNER

(Gardener to the Duke of Northumberland),
Albury Park Gardens, Guildford.

FOR NORTHERN GARDENS.

The Kitchen Garden.

Late Sowings of Carrots.—Profitable sowings of the Early Short Horn varieties may yet be

made, utilising ground that has been cleared of early Potatoes. The Stump Root type matures quickly and will be ready for use by October.

Purple Sprouting Broccoli.—Where this variety is favoured no time should be lost in getting a quantity planted out. This sort proves useful in furnishing an early crop. Allow 2ft. each way between the plants, choosing a fairly rich and sheltered part of the garden.

Globe Artichokes.—Give these plants a generous mulch of half-rotted cow manure, so that a prolonged crop may be ensured. On light, gravelly soils frequent waterings should be given, both of pure water and of liquid manure.

Swedes.—Seed may be sown until the second week in July, which will produce nice sized roots for winter use. Sow a good field variety, as these seem to be more satisfactory than the so-called garden varieties, which generally produce more "neck" than root.

Cabbages.—Mid-season Cabbages that are for any reason slow of growth may receive a stimulus by giving a judicious application of sulphate of ammonia. Work the ground freely between the plants, and hoe up immediately the plants attain a reasonable size.

Celery.—Take advantage of showery weather to plant out further lots of Celery. Early batches which are well established should be given weekly applications of liquid manure from the byre, varied at times with soot water.

Fruit Under Glass.

Vines.—Mid-season Vines on which the fruit is swelling should be assisted with copious waterings of manure in liquid form, so that the development of large berries may be encouraged. Afford plenty of atmospheric moisture, allowing a free circulation of air, so that scorching of the foliage and scalding of the berries may be avoided. A chink of air may also now be left on over-night. Where the drainage is good and the soil of light texture, outside borders require to be well watered occasionally. Mulching is also of great benefit to the Vines, and considerable assistance may be derived from a surface sprinkling of Thomson's Vine Manure, given before watering.

Peaches in Pots.—Immediately early sorts are cleared of their fruit the trees should be stood in the open, where the wood may be allowed to ripen in a natural manner. Plunge the pots in leaf-soil or ashes to keep the roots cool, seeing at the same time that the trees in no way suffer from lack of moisture at the roots.

The Flower Garden.

Climbers of various sorts are growing freely and soon get into a tangle if not attended to, thereby losing in many instances their charming effect. When tying, use discretion, as most plants of rambling habit do not look happy if tied in tightly or in too formal a manner. Where growth is crowded, thin freely and allow for the proper development of that which is left.

Sweet Peas.—Care should be taken that the plants do not at this time receive a check, as when this happens they invariably disappoint throughout the season. Regular waterings should be given during dry weather, and where facilities allow, mulch freely on either side of the row.

Herbaceous Borders.—Plants which have not been lifted and transplanted for a number of years readily show signs of exhaustion at this time, the plants being quickly susceptible to hot sunshine or lengthy spells of drought. To create a cooler influence a liberal mulch of short litter should be given, working it well round the stools and over the neighbouring surface of the border.

JAMES McGRAN

(Gardener to Sir Henry H. Houldsworth, Bart.),
Coodham, Kilmarnock.

GREENHOUSE AND CONSERVATORY.

Carnations.—The earliest rooted batches of perpetual-flowering varieties should now be ready for their flowering pots, which should be 6ins. or 7ins. in size, according to the vigour of the respective varieties. The potting compost should consist of good mellow loam, with the addition of enough coarse sand and old mortar rubble to render the whole porous. Unless the loam is very heavy, little or no leaf-soil should be added, as it renders the growths rather soft, which is not desirable. A 7in. potful of fine bone meal and a 5in. potful of soot should be added to every bushel of soil.

The plants should be firmly potted, as they dislike a loose rooting medium. For early winter flowering, the plants, if properly managed, should not require any further stopping. Later rooted batches should be potted on as they require it and may be stood outdoors for the summer; but I do not advise this, for if they can be kept in a cool house cultural conditions are under better control, especially during spells of very wet weather. Watering must be carefully done at all times, and attacks of aphid and red spider guarded against. For anyone with limited greenhouse accommodation Carnations of this class are about as useful as anything, as one should be able to have flowers all the year round.

Border Carnations that have been grown in pots and have finished flowering should now be layered. For this purpose it is best to turn them out of their pots and plant them in a cold frame, or even in the open ground, layering the strongest shoots in the usual way.

Stocks.—Where grown for winter flowering, seed should be sown thinly without delay. If the seedlings are overcrowded they are very liable to damp off. The seed pans may be stood in a cold house or frame, shading them until the seed germinates. The Beauty of Nice type, All the Year Round, the intermediate so-called Covent Garden type and Lothian Stocks are all useful for winter and spring flowering. In the country with plenty of light it is easy to have them in flower during the winter. In the immediate neighbourhood of London, for lack of winter light, it is hardly possible to flower them successfully during the winter. Under such circumstances it is best to grow them for spring flowering. In such cases September is early enough to sow the seed. When large enough to handle, the seedlings may be pricked off into boxes or put directly into thumb pots. The potting compost should be the same as recommended for Carnations, remembering that lime is essential. The plants should be potted firmly, and 6in. pots are large enough for them to flower in. During the summer they may be stood in cold frames, exposing them fully to light and air. During continued spells of wet weather the frame lights should be put on, as the plants are impatient of too much wet at the root. When the seedlings are some 3ins. or 4ins. high, the singles can generally be distinguished from the doubles by their narrower leaves and more slender habit.

Wallflowers.—Double Wallflowers, both dwarf and tall varieties, are very useful for spring flowering in the cool greenhouse. Seed should be sown outdoors at this time, treating them like the ordinary single varieties, and by autumn they should have made good plants, when they should be lifted and potted. The plants are best wintered in cold frames, giving them plenty of air on all favourable occasions.

Canterbury Bells in numerous varieties are also splendid plants for the cool conservatory. As the seed is very fine, it is just as well to sow it in a box in a cold frame, pricking the seedlings off outdoors when large enough to handle. Pot them up during the autumn and winter in cold frames.

Hydrangeas.—From now onwards until the end of August good strong shoots should be secured for cuttings. These should be placed singly in small pots and plunged in a close case with slight bottom heat, where they will quickly root. When rooted they should be potted into 5in. pots and may be stood in a cold frame, which should be kept close for a few days until they get established. Afterwards they should have full exposure to light and air, even during autumn and winter, when the weather conditions are favourable.

PLANTS FOR A SMALL MORAINE GARDEN

(Continued from page 208.)

CYANANTHUS LOBATUS.—A further trial of this on the moraine was not successful. It always seemed to be checked when in flower, apparently by early morning frost in August, which sometimes is a cold month in this part of the North-East of England. From my experience I should not consider it a suitable plant for an open, exposed moraine, but for a more sheltered position and in richer soil. It was flowering beautifully in the Edinburgh Botanic Gardens last September, planted almost at the path level in a situation well sheltered from the morning sun, but receiving the mid-day and afternoon sun; it was also

C. tyrolensis, only another name, apparently, for a most aggressive form of *C. pusilla*.

D. arvensis. This is like a dwarf *D. casius*, forming a compact grey cushion from which spring pretty rosy pink flowers. Appears to be very happy.

D. Freynii. This grey-leaved dwarf compact plant still flourishes in its original position, the fairly large sized almost stemless flowers in my plant being white with a pink zone in place of the more usual rosy pink that is preferable.

D. neglectus. This, the loveliest of the family, flourished and flowered very freely for a time in a fully exposed position, but as it got older and the root-stock more woody the effects of damp

part of a sunk rock garden in a position fully exposed to the sun and apparently in soil containing a considerable proportion of leaf-mould. Slippings which were kindly given to me failed to establish, owing to the conditions at the time being very difficult for propagation. When seen at its best it is a lovely plant with good-sized bright rosy flowers on short upright stems springing from a mat of bright green foliage.

D. sylvestris. This did very well, but as the flowering stems thrown up were about 12ins. long and overhung other plants, it was removed from the moraine into another part of the garden, which, unfortunately, it did not approve of. However, it will have to be replaced from seedlings that I now have raised from seeds obtained in the Alps two summers ago, but a position on the outer edge where it can overhang will be more suitable for it.

Other *Dianthi* that find a place are *D. petraeus alba*, which has remained quite healthy and compact; while somewhat increased in size, it does not unduly encroach. *D. integer*, with a somewhat similar green foliage, is more compact and throws up white fringed flowers on shorter stems. The plant under the name *D. Lereschei* that I have does not seem to fit the description. The foliage, which is short, grassy greenish grey, seems about right, but the flowers, which are white, smallish in diameter, are thrown up on 3in. stiff stems. It increases very slowly and, flowering somewhat later than most of the other *Dianthi*, is both useful and quite worthy of a place. *D. microlepis*, a dwarf, compact species somewhat similar to *D. Freynii* in its best form, with bright rosy red almost stemless half-inch flowers, cannot very well be dispensed with. The great difficulty is in the winter to prevent it from being loosened out. The roots seeming to take very slight hold of the soil, are only too easily loosened out by frost and thaw and succeeding rain. This to some extent is prevented by laying a stone partially over the edge of the plant, and it is possible that glass protection would help to keep it in its place. *D. casius Bickhami*, has the usual tufts of glaucous leaves more compact, with deep rose red flowers on short upright stems.

The plant referred to as this in 1917 and received by me as such was quite different, although the foliage and flowers were similar, but much stronger growing, and flowers on longer pendent stems. *D. subcaulis*, a small greenish tufted plant, has rosy pink flowers of smallish diameter on about 4in. stems. *D. Wimmeri*, which is said to be a form of *speciosus*, has deep crimson flowers on long stems, flowering later than most of the other Pinks; only suitable for overhanging the edge of moraine.

Eritrichium nanum.—This brilliant blue gem of the High Alps as yet has not been tried. It appears from Mr. Farrer's own showing to be very difficult and, even on moraine, short-lived.

Heris petraea.—Very dwarf evergreen Candy-tuft with somewhat stiff branched foliage and the usual white flowers on short, erect stems; quite desirable. My plant, received from a friend in 1917, has been very slow in growth and very unlike the other members of that family.

T. ASHTON LOFTHOUSE.

(To be continued.)

THE BRILLIANT DIANTHUS NEGLECTUS ON THE MORAINE.

partially shaded by other plants with which it was associated.

Delphinium nudicaule.—Very effective with its uncommon red flowers in June. Quite happy for four or five years, but requires renewal from time to time, and this is fairly easy as, if allowed to seed, seedlings usually come up in the vicinity.

DIANTH.—*Dianthus alpinus*. Further experience has somewhat modified my early ideas as to this lovely Pink. Very few of the original plants referred to in 1917 exist now, and what do are not in very good condition. Successive wet and frosty winters have a deteriorating effect, causing the roots to loosen their hold of the soil, with the result that they decay and die, helped as plants are, especially if unhealthy, by various pests. It will, I am afraid, require occasional renewal, and it appears to succeed and live longer if it does not receive the sun until the morning is well advanced. It has done very well in a position (not on the moraine) that receives the afternoon sun, but this plant is badly feeling the effects of a *Campanula* that was received as

and frosty intervals in the winter eventually terminated its existence. It is, however, easily propagated by slippings or raised from seeds, and is worth a little trouble to maintain. The plants, however, seem to me happier and healthier in a less exposed position and possibly to have a longer life. It usually flowers twice if the earlier flowers are cut off before running to seed.

A *Dianthus* received from a friend's garden as *D. alpestris* seems to be a form of *D. neglectus* with exactly similar deep rosy pink flowers with buff undersides to the petals, but on wavy, pendulous stems about 6ins. long which are very effective planted on the outer edge of the moraine. The foliage is a similar green, but longer and less compact. A considerable amount of old crushed plaster or mortar is used by me for top-dressing most of the *Dianthus* family, which are also usually planted in a compost containing a good percentage of the same.

D. glaucus. In a North Yorkshire garden at the end of May, 1920, a magnificent lot of plants were seen in full flower, planted at the upper

The "VILLA" SPRAYER

PATENT NO. 161730.

BRASS CYLINDER
17 IN. LONG
X 7/8 DIAM.

"The Villa" Sprayer is now fitted with a new and greatly improved nozzle. It is connected to the pump with the same sized screw as the old pattern, so that the old one may be unscrewed and replaced by that shown in the cut above. Instead of the inlet valve being operated by a rubber band a BRASS BALL VALVE has been substituted. There is nothing whatever to go wrong or to corrode. The liquid may be sucked up from the very bottom of the can by loosening and tightening the brass screw the spraying tube may be set to throw the spray at any desired angle, and it is more solidly constructed. Former customers may be supplied with this new nozzle, post free, 1/-.

THE TRADE SUPPLIED. For Wholesale terms apply: G. W. JONES, 156, Holdenhurst Road, Bournemouth.

DECORATIVE ROSES FOR HOUSE AND GARDEN

SPEAKING generally, the Roses we find most suitable for the decoration of our gardens are also the best Roses to use for arranging in our houses. Therefore as this season is the time when most of our Rose gardens are at the height of their freshness and beauty it may be that a short tour of the garden will show us which Roses are likely to be good for both purposes.

We grow our Roses either in beds of one variety or in groups of twelve to twenty-four plants in long borders, and thus we are able quickly to see those which are the most decorative from a garden point of view. The red Roses first catch my eye.

General McArthur with its ample foliage, delightfully upright habit and fragrant crimson flowers, freely, but not too freely produced, is the type of plant which is almost ideal both for house and garden decoration. The flowers should be cut before they are half-opened (this applies to all single and to most decorative Roses), for the colour is then far brighter than if they are allowed to expand on the plant.

Richmond, another fragrant red Rose, makes an excellent bed, but it needs constant disbudding, otherwise the flowers come of a poor form and colour, whereas, if disbudded, both in form and colour it is superior to General McArthur; but the growth is not so strong nor the foliage so ample. Mrs. Edward Powell is a brilliant red Rose with very strong growth and fine dark bronzy foliage. The form of the flowers is rather poor, but they are produced abundantly. Red Letter Day and K. of K. are two of the most highly coloured of our red Roses, and both are excellent for the garden, also for the house if they are cut when very young. The flowers are almost single. With us Red Letter Day is the stronger and more upright grower, but K. of K. is the more brilliant of the two.

In a garden we visited two or three days ago in the neighbourhood of Canterbury some very tall standards of Hugh Dickson, full of bright crimson flowers, were extraordinarily decorative. This variety is, perhaps, a little heavy as a cut flower, but if cleverly arranged it can be made to look very handsome in a big bowl. Hoosier Beauty has every virtue a crimson Rose can boast—depth and richness of colour, good form and delicious perfume—but it has one bad fault which prevents it being a good Rose for garden decoration, namely, that it hangs its head. If used as a cut flower it generally requires wiring, but in spite of this drawback it is so beautiful we can hardly dispense with it.

The most fashionable tints among the Roses of the present day are no doubt those of deep

comment. Personally, I prefer it in the garden, where its somewhat hard colouring is softened by the various lights that play on and through it, to its appearance as a cut flower, especially as, when cut, it almost immediately hangs its head; also its superabundant thorns, which in the bed rather add to its beauty, are a distinct disadvantage when one wants to put the cut flowers quickly into a vase or bowl. Other Roses of this colour but with softer tints and less thorny stems are Lady Pirrie, Henrietta (very sweetly scented), the new Padre and the old China Comtesse du Cayla. This last, if very slightly pruned, will grow into a big bush and give quantities of its pretty buds till November. Lamia, Severine and Emma Wright are all varieties with flowers of somewhat similar shades of orange, bronze and apricot; while the almost single Old Gold has added tints of salmon and pink. They are, however, not quite so strong in growth as the other varieties I have mentioned.

Among the brilliant yellow Pernet varieties we have found Golden Emblem and Mrs. Wemyss Quinn decidedly the strongest growers. They throw up long stems, which makes them useful sorts to grow as cut flowers, though I always think these golden yellow Roses lose somewhat of their attraction when brought in to the house. Christine is also a fine golden colour, but is perhaps not so strong in growth as could be wished. The new variety Rev. F. Page Roberts promises well.

C. E. Shea, Mrs. Glen Kidston and Dorothy Page Roberts all make delightful groups of bright salmon rose tinted blossoms, and are worth growing for indoor or outdoor decoration. Mrs. Glen Kidston has a decided perfume.

In hot weather such as we had last summer some of the cooler shades are very welcome. The flesh pinks are abundant. Rénée Wilmot Urban,

INVALUABLE FOR MASSING AND EXCELLENT FOR CUT FLOWER—THE BRILLIANT ROSE LADY PIRRIE.

salmon orange, terra-cotta, bronze, copper and brilliant yellow; and in the Hybrid Teas and Pernetianas an almost bewildering number of these are to be found. Mme. Edouard Herriot is still the most effective of the terra-cotta shades in the garden. It is so erect in habit, so brilliant in colour and so extraordinarily free in flowering that no one can pass a bed of this variety without

not often seen, but very strong, and during the summer, at any rate, making exceedingly pretty, and well formed flowers, is worth a place in the garden; so are La Tosca and Pharisæer, the latter often being good enough for exhibition. La Tosca, if allowed to grow into a good-sized bush, puts up long, smooth stems with loose, artistic flowers which are specially delightful for tall vases. Mme. Léon Pain, a deeper salmon flesh, is quite the best garden Rose of this colour, but for some reason the flowers are apt to be a little disappointing and heavy when cut.

have expanded they open well indoors and last for a considerable time in water.

The Rugosas, which make fine bushes for garden decoration, are not good as cut flowers. They seem to shrink and fade quickly when cut. The chief use to which I put their exceedingly fragrant blossoms is to make them into pot-pourri. For this purpose they are unequalled.

In so short an article I can hardly write of the Climbing and Dwarf Polyanthas, or the Wichurianas, which through June and July add colour and gaiety to our gardens, many of which are most

Paul's Lemon Pillar, with large, perfectly formed lemon white flowers; and Paul's Scarlet Climber, the most brilliant red climbing Rose we have.

In the long evenings which "summer time" gives us we have ample opportunity for observing which Roses are the most effective for the garden, namely, those with clear, bright colours, good foliage and upright habit, the flowers being borne on stems which are sufficiently strong to hold them upright; and these, especially if they can be cut with long stems, are the Roses which we

THE RICH SALMON-PINK CHARLES E. SHEA.

AN EXCELLENT REDDISH-ORANGE ROSE—LAMIA.

Ophelia stands alone as a beautifully formed and fragrant Rose of pale flesh flushed in the centre with orange or pink. It is a refined Prince de Bulgarie, and is one of the most charming of flowers for the house.

Mrs. Herbert Stevens and Molly Sharman Crawford (Teas), with Mme. Jules Bouché (H.T.), are perhaps the best white garden Roses we have, though White Killarney, when grown under glass, is quite as useful as a cut flower. In the garden it is too much addicted to mildew to be a good bedder.

The cooler shades of pink are not fashionable at the present time, but they too have their charms. Mrs. E. G. Hill, pale pink with deeper reverse, puts up loose panicles of flowers which look well in the garden or the drawing-room, but they must not be put near any of the Mme. Edouard Herriot shades of colour or both tints will lose much of their beauty.

Among the Roses which will form big bushes we have found Moonlight, a Hybrid Musk, introduced by Mr. Pemberton, quite one of the most attractive. It puts up huge sprays of bronzy red, with large heads of small creamy white flowers. If these are picked before the blossom

useful for house decoration. Two pillar Roses, which as I write (June 24) are in the fulness of their beauty, call for special mention. These are

shall like to bring into our rooms, and for this purpose we shall also prefer those which to their other charms add that of fragrance. WHITE LADY.

HARDY HYBRID RHODODENDRONS IN 1922

Now that the Rhododendron season is on the wane and the hardy hybrids are near their finish, some reflections on the past flowering season may be made.

SO far as the earlier varieties were concerned, the conditions of weather prevailing at the time of flowering was almost ideal and, consequently, some magnificent blooms of such varieties as Pink Pearl, George Hardy, Loder's White, Alice and others of about this same period were seen to the finest advantage. Later, the extreme heat developed blooms at such a pace that their greatest effect was not such as would have been the case had more favourable conditions of weather prevailed. The later blooms, and more particularly those in

flower in the third week in June, owing to the considerable change in the weather, came out magnificently, and where freely planted made as grand a show as has ever been seen.

Undoubtedly the warm weather of last year, notwithstanding the extreme conditions of drought, had one effect, namely, the thorough ripening of wood, which has affected in a flowering sense not only Rhododendrons, but almost every flowering tree and shrub to such an extent that there is a flower on almost every available shoot, this being due entirely to the thorough ripening of

the wood. I suppose no such flowering season has been seen for many years. Such familiar plants as the Hawthorn, Cherries, Chestnuts, Acacias and Laburnums have been covered with a mass of bloom, and a similar condition has prevailed with the more shrubby flowering things, such as Rhododendrons, Azaleas, etc. The past winter, with its catchy periods, proved detrimental to the more tender varieties of Rhododendrons, more particularly those grown in localities to which they are not essentially adapted, and must have proved in many cases a considerable disappointment, and this one point leads me to enlarge upon the advantages of the strictly hardy hybrids, without which such counties as Surrey and Berkshire, and almost any county outside of the favoured few on the western seaboard and to some extent the limited number of favourably situated gardens on the southern slope of the hills of Surrey and Sussex, would have a comparatively poor show of massed bloom, as such can only be obtained there from the hardy hybrids.

Referring to the favourably situated gardens of Surrey and Sussex, here in woodland planting it is possible to obtain successes with a large number of semi-hardy hybrids and species that it is not possible to deal with even twenty or thirty miles away except the conditions be most favourable, and in one or two instances known to me there are examples of these more tender varieties succeeding, but their average annual show does not compare in any sense with that provided when the hardy hybrids commence to flower about the middle of May and onwards.

Recently, I have been in Devonshire and Cornwall, and in the case of the former was much impressed by one or two instances of the glorious effects of hardy hybrids planted perhaps forty or fifty years ago, and in one particular instance I have seen magnificent specimens of well known varieties, such as Broughtonii, Cynthia and others, carrying from 5,000 to 10,000 heads of flowers each. Seeing these plants in perfection, as I did, was a revelation even to me, who may be said to breathe Rhododendrons from one year's end to another. I took the rough dimensions of a plant of Cynthia in particular and estimated it to be 18ft. to 20ft. in height and 5ft. in circumference. The plant was in good health and carried a truss on almost every available shoot, the trusses being well developed as if it were only a young plant. I need hardly say that such a sight was worth going 200 miles to see.

I have often been told and have seen in print that the flower of Rhododendron Pink Pearl deteriorates in size as the plant grows older, and I confess, seeing how badly a large number of plants are cared for in private gardens, that this particular point has given me a great deal of disappointment from time to time; but during my visit to Devonshire I happened to see a plant of Pink Pearl some 10ft. in height from which the owner had disbudded some 50 per cent. of the bloom buds, leaving some 250 to 300 trusses to develop, and I do not hesitate to say that no finer blooms could have been seen. Many of the individual flowers were 5½ins. across. Attention must be given to anything in the garden to obtain its very best results, and I see no reason why equal attention should not be given to Rhododendrons as to many other plants in the garden which by average gardeners are well cared for.

One does not have to go very far to see the disadvantages of bad cultivation. I know I am treading on dangerous ground, but during the second week of June I went to Kew, partly in response to a note which I saw in the daily papers that the following Sunday was to be regarded as Rhododendron Sunday. Here, I thought, was my opportunity to see Kew at its best. I was

grievously disappointed. The Rhododendrons in the dell were looking fairly satisfactory, but consist of many very old-fashioned types, which have been superseded in the last thirty or forty years by the introduction of better things, but what impressed me most was the condition of some of the beds in the open. I examined these carefully and found no signs of assistance in the way of a mulching to retain the moisture, and in many cases the roots of plants were actually visible. In consequence, they were nearly dried up and the blooms refused to expand for lack of moisture and sustenance. I submit that such a condition in our national garden should not be tolerated for one moment. In my view there is no more pitiable sight than to see plants in a half-starved or badly cultivated condition, and my feeling in seeing such plants is just the same as I have towards a cripple. There does not seem to be any particular necessity for me to enlarge on this point, but if plants are worth having at all they are worth looking after properly.

The Rhododendron is a plant which cannot be planted everywhere and, in fact, on certain soils containing lime in any form it is ridiculous to make preparations to receive these plants. The cost of establishing anything like a satisfactory compost for them to thrive in for any length of time is prohibitive, and even where, after treatment, plants succeed for a time, sooner or later the surrounding lime permeates to the prepared soil, with consequent failure of the plants. There are other soils, such as a very unkind clay or soils entirely lacking in fibre, where Rhododendrons do not thrive. That Rhododendrons can only be grown on a peaty soil is quite wrong. Probably the most favourable soil is a light fibrous loam, and I have knowledge of many Rhododendrons growing exceedingly well in soil which does not contain peat in any form. Undoubtedly the ideal conditions for Rhododendrons are to be found on certain districts of the "Bagshot Sands," more particularly in the valleys, where Nature has washed for centuries the better soil into the lower sections forming a deep surface of suitable compost largely of a vegetable character, while underneath the drainage is perfect. The "Bagshot Sands," when properly cultivated, are capable of supporting Rhododendrons to the very best advantage.

One of the finest Rhododendron soils to be found is in the neighbourhood of Heaton Mersey, near Stockport. This consists of an alluvial sand,

the upper portions containing a fair amount of fibrous loam. There are some magnificent Rhododendrons to be seen in this district, and the blooms produced are of the finest quality. Ideal

THE MANGLES HYBRIDS HAVE DONE WELL THIS SEASON.
ISABEL MANGLES, A PARTICULARLY FINE ONE.

conditions can also be found in many woods in all parts of England; in fact, the woodland planting of Rhododendrons is still in its infancy. The knowledgeable amateur has already found that much better results can be obtained not only in the quality of the bloom, but in the growth of the plant, and more particularly in the maintenance of the true colour, which in many Rhododendrons, when fully exposed to the sun's rays, is soon bleached and taken out of character.

In the North of England and in Scotland Rhododendrons and many other flowers are able to stand the full exposure of the sun, which is not so powerful as in the South, the atmospheric conditions being quite different. In the course of my business I have often been taken round gardens and shown successes or failures, and the many failures that I see are due entirely to lack of judgment in the placing of beds. Sometimes a draughty spot may be selected, or one on a southern slope where drainage and evaporation prevent any moisture remaining to serve the plants. Again, many Rhododendron beds are formed in a shape resembling a hog's back, and the poor plants that happen to be on the top of such an elevation probably never become thoroughly moistened after once being placed in position.

In other articles I have referred to the manner in which the average gardener rakes and sweeps up all the nourishment provided by Nature without attempting to replace it. A pricking over of the beds from time to time and a mulching of peat or leaf-mould, with, perhaps, the addition of

some cow manure, would make a marvellous difference to the well-doing of plants distributed in beds where ordinary nourishment does not reach them. In woodland planting, more particularly in wild form, Nature looks after these things to some extent, and although the original preparation of the ground should be thorough, in this case the after-care is never onerous. Dry seasons, such as we have experienced last year and to some extent already this season, show very clearly the contrast between proper cultivation and the lack of any care and attention.

Perhaps it may be of interest to mention Rhododendrons that I have this year seen flowering in fine form, and first I should like to name *Smithii album* or *Bodartianum*. This beautiful white, although flowering early, came through some very bad weather, and a large plant in the Bagshot Nurseries flowered almost to perfection. *Ascot Brilliant* was also very satisfactory this year, and this was followed almost immediately by *J. G. Millais*, a very fine Rhododendron owing its parentage on one side to *Ascot Brilliant*. It is said by many to be one of the finest hybrids ever sent out by the Bagshot Nurseries, and undoubtedly as a fairly hardy early Rhododendron it is very hard to beat.

Coming to the later section of Rhododendrons but still among the early forms of the hardier hybrids, *Pink Pearl* flowered grandly, and *Alice* probably has never flowered better. This grand variety may be said to rival *Pink Pearl*, not only as to beauty, but as regards general character and as an all-round garden plant. The old variety *Cynthia* has flowered magnificently this year, so have *George Hardy* and others of the *Mangles* hybrids, with the exception of the narrow leaf form which is usually known as *Manglesii*. This had suffered considerably in the bud at Bagshot and did not flower particularly well.

Bagshot Ruby and *Corona* proved again their great merit, and *Bernard Crisp* was magnificent where it was not exposed to the full rays of the sun.

Perhaps one of the best Rhododendrons of the later section is *Donald Waterer*. This beautiful deep pink with its yellow marking has been for a matter of a fortnight a prominent feature in the nurseries. Other varieties which have flowered particularly well this year may be mentioned as follows, namely, *Francis B. Hayes*, *Gomer Waterer* (of its type the finest Rhododendron yet produced), *Duchess of Teck*, *Michael Waterer*, *Frederick Waterer*, *Lady Cathcart*, *John Henry Agnew*, *Mrs. William Agnew*, *Minnie* and so on. It would be impossible to enumerate all the varieties that have been seen to flower well this season in favourable conditions, but it would not be right to pass over the particular merits of *Mrs. E. C. Stirling*, which produced some magnificent blooms this year, and the very old *Mme. Carvalho*, which even at the end of the third week of June was still very beautiful.

One thing which has much impressed itself upon me this year, although I have always known it, is the great beauty of some of the oldest hybrids. I refer to varieties raised some forty or fifty years ago. It is true when in the small state these sorts may be passed over, for it is only when they are sizeable plants that they begin to show their great merits. Such varieties as *John Waterer*, *Michael Waterer*, *B. W. Currie*, *Lady C. Mitford* and *H. W. Sargent* when seen as big plants are wonderfully beautiful. F. GOMER WATERER.

Mr. Waterer sent a photograph of the fine flowered specimen *Pink Pearl* to which he makes reference, which bears out his statement as to the vigour of the plant and size of the blossoms. Unfortunately the photograph is unsuitable for reproduction.—Ed.]

THE DEVELOPMENT OF THE CARNATION AND ITS HYBRIDS

ADVANCE in horticulture is so slow, so gradual, that to the average gardener it is scarcely noticeable, yet certain flowers at certain periods have, as it were, their revelation, and the old order of things becomes changed. Such an upheaval has taken place with the *Orchid* and the *Rose*. Floral

than the earlier American varieties; also they are more productive.

The greatest trouble with this delightful race of Carnations is that people will persist in coddling them with too much artificial heat and insufficient ventilation; also they will add leaf-mould to the potting soil, which the plants abhor. All the *Dianthus* family, in fact, grow better without it.

BORDER CARNATIONS.

The old type of Border Carnation retains its popularity and, undoubtedly, the more modern varieties are considerable improvements on those of, say, fifteen years ago. The National Carnation and Picotee Society are encouraging more and more self-coloured garden kinds rather than purely exhibition varieties, hence the more recent kinds are easier to cultivate and will flourish in any sunny garden.

THE NEW HARDY PERPETUAL "BORDERS."

This new race of Carnation, like *Allwoodii*, is being despised by one Carnation society and rejected by the other. Even the R.H.S. refuses to recognise it; however, the general public, who alone really matter, have taken most favourably to them, and when stocks permit and prices are reduced they will be found in almost every garden because of their hardiness, freedom of flowering from June to October outdoors, fragrance and ease of cultivation. The *Perpetual Border* is a cross-bred race and, like most cross-breds, has almost an excess of vigour. The formation of the flowers is not quite so perfect as with the old-fashioned Border kinds, but all have smooth-edged petals with a delightfully wide range of colours.

They grow freely in any sunny garden. Like all Carnations, they abhor leaf-mould, but love a little old mortar rubble or lime added to the soil.

They may be planted in the garden at any season. Cuttings root readily in sand from plants growing outdoors during the summer months, or layers may be taken. The young plants are, like all *Perpetual Carnations*, stopped at the sixth pair of leaves, and in the garden they grow almost into bushes.

THE BORDER PINK AND ITS HYBRIDS.

The homely, unassuming little *Pink* was once one of the most popular of garden flowers. Innumerable raisers of new varieties competed with each other at the various *Pink* shows, and they had elaborate rules as to the various formations and markings of the flower, until it was lifted right out of its sphere of usefulness as a common hardy garden flower and gradually lost popularity; these elaborate laced exhibition varieties fell out of favour to the public, the little *Pink* sank right back to a very lowly estate, and the old variety, *Mrs. Sinkins*, which was an outcast, alone retained the popularity of its kind. Happily to-day we have many new forms of *Pink* being raised and exhibited, some hybrids, others not. Mr. Herbert and Mr. Douglas have many magnificent seedlings.

Allwoodii, which are half *Pink* and half *Perpetual Carnation*, but which resemble *Pinks* in habit, should restore the popularity of the flower, even without the motherly care of the floral committees, which often lack imagination. The public will not tolerate any variety of *Pink* which is not sweetly scented or lacks a robust constitution, also they must be perfectly hardy. For myself I think the *Pink* should be "perpetual" flowering from spring to winter out of doors.

A TYPICAL PERPETUAL MALMAISON CARNATION.

committees often oppose this hybridisation and introduction of new types, but floral committees, like governments, cannot oppose for long the will of the people, so new and popular races of plants, such as the *Hybrid Tea Rose*, become generally recognised and in course of time almost entirely supplant the older kinds; this in a measure may be sad, but it is after all merely evolution.

The changes which are taking place in the Carnation world to-day could not have taken place twenty years ago, because the *Perpetual* type of Carnation at that time was not sufficiently fixed or developed to have the influence it has to-day; even now the work is done with highly developed seedlings, not the named varieties in commerce.

MALMAISONS.

The old type of blush, *Souv. de la Malmaison*, made popular years ago by the *Empress Josephine*, has become little more than a memory, and the glorious deep pink *Princess of Wales*, which *Queen Alexandra* made the flower of fashion, has also lost favour, simply because the newly introduced *American Perpetual Carnations* supplanted them. To-day, however, we have the *Perpetual Malmaison*, which, defying time and season, is always in bloom. In colouring the varieties of this new type are more beautiful than their predecessors and, in a few years, we shall see the new *Perpetual Malmaison* reigning in its rightful place as the aristocrat of the Carnation world. Its cultivation is much easier and simpler than that of the old type. It is best grown under glass the entire year, with just a little heat in winter, like the ordinary *Perpetual-flowering Carnation*, in fact, the two live neighbourly together, requiring the same cultivation.

PERPETUAL-FLOWERING CARNATIONS.

The present-day varieties are improvements mainly because they grow much more easily

As regard: cultivation, a variety of Allwoodii or Pink which calls for special cultivation and care is not desirable. In my opinion all that they have a right to expect is a sunny position, and any soil can be made to their liking by the addition of a little air-slacked lime or old mortar rubble. Cuttings root readily from June to September, and these when rooted can be planted in the garden at any season.

For myself, I believe we have only just begun to develop the Divine Flower, that all sorts of beautiful new plants with flowers of varying forms and colours will presently be seen. The use of the delightful old-fashioned Sweet William and Alpine Dianthus for interbreeding may well open up almost a new floral kingdom; such is evolution.

Haywards Heath. MONTAGU C. ALLWOOD.

TULIPS IN WALES

EVERYTHING must have a beginning. There was a time when there were no Tulips in Holland. The many millions that can be found there to-day were once represented by a few rows in a kitchen garden! Wales has produced a very famous Prime Minister. Why should she not produce equally famous Tulips? As far as I know there is no reason whatever. She has made a start. There are small Tulip centres at St. Asaph and at Llanfair P. G., where the bulbs thrive amazingly. Anyone who happened to visit the last Chelsea Show might have seen for themselves the truth of my last statement in the exhibit put up by the Anglesey Bulb Growers' Association. As exhibits go at this big Show, it was not a large one, so what gained for it the high honour of a silver cup was not size, but quality. I was immensely taken with what I saw, and had I not been assured by Mr. Watts, who was in charge, that all had been cut from the open just as they were, I should have come away thinking that the big blooms were the result of glass or protection of some kind, together with high feeding. Already those responsible for the management are casting about for more suitable land. I rather think that some which I happen to know from passing it in the train, has been provisionally thought of, if the very necessary item of acquisition can be fixed up. I have twice seen "Holland in Ireland," as the bulb fields of Messrs. Hogg and Robertson at Rush have been playfully named. If I am not greatly mistaken before very long we shall be able to see a "Holland in Wales." There is no earthly reason why it should not be so. Suitable land is there all right. In my opinion it all depends on the human factor. Knowledge, thoroughness, gumption and labour are all equally

as necessary as good ground. Given these the culture of certain bulbs as a business proposition is well within the bounds of possibility. What a

of Holland have adapted themselves to circumstances. To a large extent, however, the best land for Hyacinth growing had almost all gone, and the expense of getting less suitable land into a proper condition was becoming exceedingly heavy, so the change (if it was a little galling to find the special flower of Holland was becoming less and less appreciated by the flower-loving world), had the substantial compensation of a bigger volume of trade than ever. For years we Britishers have been rubbing our eyes. That is how we may look upon what we have done in the past. It is about time we really woke up to the possibilities of our own land. If the purchase of many acres of land in Lincolnshire by some keen and enterprising Dutchman is not sufficient a prod to make us open our

WELSH TULIPS.

change has come over the bulb trade within the last half century! Well within living memory it was all Hyacinths, early Tulips and bunch-flowered Daffodils (*polyanthus Narcissi*) in the ancient home of the bulb-growing industry. Now it is Daffodils of all kinds, May-flowering Tulips and Hyacinths. It is very wonderful how the growers

eyes, what would be? In the past we have not been sharp enough to see the chance the change of taste opened to us in Britain—at least, few of us have been. There have been exceptions. If we had all been Walter T. Wares the history of bulb growing in Britain would have been different. There would have been far more British grown bulbs to-day for the British to buy, and their general quality would have been better. There is no weeping peace when there is no peace any more than in living in a fools' paradise with regard to our home productions. Insular pride cannot turn one goose into a swan. I have bought British grown Tulips from various sources. I regret to say I have found the samples of very varying quality—good, bad and indifferent. This must not be. If we want our own people to buy our home-grown bulbs—if we want this industry to grow larger and become more important—we must offer for sale none but those which come up to the high standard of the Dutch. I believe this is what the Anglesey Bulb Growers have set before themselves in taking up the cultivation of the Tulip. To see for myself the type of bulb they could supply I bought five hundred bulbs of the well known Darwin Clara Butt last autumn. Now that I have both handled the dry bulbs and seen the quality of the blooms these same bulbs have produced in my own garden, I can confidently say that my friends in Anglesey have made a most promising start and that there is no reason why their venture should not be crowned with success. Seeing is believing, except when you are, say, one of the audience at "Maskelyne's." Photographs in THE GARDEN are above suspicion. Tulips in Wales even now are no myth. JOSEPH JACOB.

ANOTHER VIEW.

THE GREAT SUMMER ROSE SHOW

THE success of a flower show usually depends largely on the weather, and although the early morning of June 20 was not too promising, there was a very large attendance at the Summer Show of the National Rose Society held in the Royal Botanic Society's Gardens, Regent's Park. Generally, the day was fine, but there were several very heavy showers which compelled the visitors who had temporarily left the tents hurriedly to seek shelter. But between these showers the weather was pleasantly fine, and the bursts of sunshine were tempered by a cool breeze which added to the comfort of those in the tents and kept the blooms fresh throughout the day. The general quality of the blooms was quite the highest for the past seven or eight years at least, and the entries were also the largest of recent years, and as probably 25 per cent. of these were from new exhibitors, this augurs well for the continued prosperity of the Society.

Silver medals were awarded to the following as being the best blooms of their respective types in the Show. Nurserymen's Classes: Louise Crette, H. P., shown by Messrs. G. and H. Burch; Mrs. George Marriott, H. T., by Messrs. Alex. Dickson and Sons; Mrs. Campbell Hall, T., by Mr. George Prince. Amateur's Classes: Candeur Lyonnaise, H. P., by Mr. S. W. Burgess; Mildred Grant, H. T., by Mr. A. R. Reeves; and W. R. Smith, T., by the Rev. F. R. Burnside.

The increased exhibits and high quality were very noticeable in many of the amateurs' classes. The Champion Trophy was again won by

Mr. H. L. Wettern, Oxted, who had thirty-six excellent Roses. The best were Avoca, Her Majesty, Freda, Hugh Dickson, Mrs. J. Welch, George Dickson, and Mrs. F. Dennison. Dr. R. E. Turnbull, Colchester, was a good second, but while many of his blooms were very large and shapely, they were not so even as the champion collection and they showed more signs of the stress of weather. Dr. Turnbull had exceedingly good specimens of H. V. Machin, Hugh Dickson, Mrs. Edward Mawley and Lyon Rose.

In the class for twenty-four distinct blooms the competition was also quite good and here Mr. John Hart, Potters Bar, won the Edward Mawley Challenge Cup with a very even collection which, however, were a trifle weather-stained. His outstanding sorts were J. L. Mock, Mrs. J. Welch, Mildred Grant, Gorgeous and Mrs. Elisha Hicks. In Dr. Turnbull's second prize set the best were Mrs. George Marriott, a variety that was shown consistently well throughout the amateurs' classes, Rev. F. Page-Roberts and Lemon Pillar.

Of the many good exhibits of twelve distinct blooms the best was by Mr. J. E. Rayer, Worcester, who had especially fine blooms of Candeur Lyonnaise, Mrs. George Marriott, Mrs. Theodore Roosevelt and Mme. Jules Gravereaux. Dr. T. E. Pallett, Earls Colne, ran the winner very close, shewing very good examples of George Dickson, Mrs. Henry Morse and Lemon Pillar. Dr. Pallett was first in the next class, which required three blooms each of eight varieties. His best sets were of Mrs. J. Welch, Mildred Grant and Mrs. George Marriott. Mr. G. Speight, Market Harborough, the

second prize winner, had a particularly good set of George Dickson.

In the section for growers of fewer than 1,000 plants the Challenge Cup was won by Mr. F. H. Fieldgate, Colchester, who, in this very popular class, had beautiful blooms of Lady Barham, Mrs. John Laing and Candeur Lyonnaise. Mr. Fieldgate also won the first prize in the class for three blooms each of six varieties with another excellent exhibit, of which Mrs. J. Welch and George Dickson were superb. Mr. R. de V. Pryor, Hitchin, had the best of many exhibits of nine blooms in the class for growers of fewer than 500 plants, where he staged George Dickson and Mrs. Charles Russell of superb quality. In the class for six blooms, Mr. F. G. Hayes, Dunster, was pre-eminent and he had a grand bloom of Madame Jules Gravereaux. Mr. J. E. Rayer had the best six blooms of any one variety in the same section, and like most of his rivals showed Snow Queen.

The extra classes for amateurs who grow their Roses unaided were very popular and included some praiseworthy blooms, the twenty-four distinct varieties that won the Nicholson Challenge Cup for Mr. G. Speight included splendid examples of Dean Hole, Lady Barham, E. Burnett and George Dickson.

The Metropolitan Classes are arranged for competition among members who grow their Roses within eight or ten miles from Charing Cross and it would seem that practically all varieties can be successfully grown in the "near suburbs." The Williamson Challenge Cup in this section was won by Mr. G. Speight. The outstanding blooms

AN EXCELLENT NEW BUTTONHOLE ROSE, THE ORANGE YELLOW LUCILE BARKER.

SOMETHING LIKE A PALER LADY HILLINGDON—MARY MERRYWEATHER.

were of Dean Hole, J. B. Clark, Florence Forrester, George Dickson, Lyon Rose, Mabel Drew, Mrs. Foley Hobbs, Candeur Lyonnaise, A. Hartmann and Mrs. Charles Russell.

Tea and Noisette Roses were a great feature of the amateurs' classes and here the first prize collections were better than those in the nurserymen's section. The Trophy was won by the Rev. E. R. Burnside with most beautiful blooms of such sorts as W. R. Smith, Mrs. Foley Hobbs, Mme. Constance Soupert and Medea. In the class for nine blooms, Mr. W. E. Moore was first with excellent blooms. Mrs. Foley Hobbs, Auguste Comte, Alex. Hill Gray and Mrs. Myles Kennedy were the very best.

The arrangement of Roses on a space 5ft. by 3ft. was a popular class. The first prize was won by Mr. Geo. Marriott, who used such sorts as K. of K., Lady Pirrie, the Queen Alexandra Rose and Golden Emblem to good effect. Dr. M. Lacroze, who was second, had a heavier but very effective arrangement. Mr. Marriott was also first with twelve varieties of decorative Roses, though the second prize exhibit was better arranged, the vases of Moonlight, Jacques Vincent, Lady Hillingdon and Mrs. Wemyss Quin were very attractive. In the class for a group on a space 3ft. by 3ft., Mrs. Oakley Fisher made a good show with such sorts as Tausendschon, Emily Grey and Crimson Rambler.

NEW ROSES.

The special tent was well filled with new Roses, and there was the usual "waiting list" of enthusiasts at the entrance. Although only two gold medals were awarded, the general merit of the new seedlings was quite equal to that of the exhibits of former years, and it is quite possible that some of the varieties that on this occasion received the secondary award of a certificate of merit will be further honoured in the future.

Alice Amos.—This is one of the best Dwarf Polyanthas (*Rosa multiflora* type) of recent introduction. It might almost be termed a miniature American Pillar, as the colouring is much like that splendid Rambler Rose, though it is a trifle brighter. The flowers are from 1½ ins. to 2 ins. across, and are freely and continuously produced. It is recommended for pot culture and for bedding. Certificate of merit to Messrs. D. Prior and Son.

Atalanta.—This graceful, free-flowering rambling climber was entered for the Cory Cup competition, and while we suspect that its delicate fragrance is not sufficiently pronounced to win that trophy, it has distinct garden merits. It is a clean-growing, vigorous variety which bears large trusses of quaintly beautiful semi-double flowers about 2½ ins. across of creamy apricot flowers which become blush coloured at maturity. Raised and shown by Dr. A. H. Williams.

Bessie Chaplin.—An excellent H.T. Rose which we anticipate will have a great future in our gardens. It is a large, shapely, full bloom, much of La France type, but not quite so silvery a pink shade of colour, though one or two mature blooms approached it. This delightful soft pink Rose is recommended for exhibition and decorative purposes, and we are inclined to add that it should be a splendid sort for standards. Certificate of merit to Messrs. Chaplin Brothers.

Captain Kilbee Stuart.—When, two years ago, this crimson H.T. Rose received a certificate of merit discerning rosarians confidently predicted a gold medal in the near future. It will probably first of all be an exhibition Rose, but will also be of great value in the garden and as cut blooms. It may be termed an improved Edward Mawley, and the stout, broad petals are of glowing velvety crimson within and shaded scarlet on the outside,

It is also delightfully fragrant. The large leaves are of a medium shade of green, a trifle inclined to paleness. Gold medal to Messrs. Alex. Dickson and Sons.

Innocence.—An elegantly beautiful single H.T. Rose of refreshing Tea Rose fragrance. It appears to be very free flowering, and the foliage is a rich dark green colour. The flowers are 4½ ins. across, stout-petalled, and their milky whiteness has just the faintest suggestion of pale blush. The buds are very pretty, of good shape and tinged with apricot. In the centre there is a fascinating little cluster of golden stamens set on short carmine stalks. Certificate of merit to Mr. W. R. Chaplin.

J. G. Glassford.

—This vigorous H.T. Rose has been shown on several previous occasions, when it must have narrowly missed award. It is a long-pointed bloom, fully double and of deep crimson lake colour that does not appear to fade with age. Certificate of merit to Messrs. Hugh Dickson, Limited.

Lady Roundway.—If a vote of the visitors had been taken this most glorious Rose would have had a gold medal, but the judges contented themselves with the lesser award. It is a free-flowering Pernetiana variety of medium size, somewhat flattish shape and delicious fragrance. The buds are heavily flushed with cardinal red, and when fully open the colour becomes a very rich orange lightly shaded with deep rose. Certificate of merit to Messrs. B. R. Cant and Sons.

Lady Verey.—In form and habit this H.T. Rose closely resembles Liberty, but the colour is a beautiful rich shell pink. The outer petals are a trifle rolled, and it is a beautiful Rose until quite fully expanded, when it becomes a trifle hollow and so not up to gold medal standard, but it should be a very useful variety for decorative purposes. Certificate of merit to Mr. Elisha J. Hicks.

Lucile Barker.—A dwarf H.T. Rose of not more than medium size, fine shape and a beautiful orange fawn in colour, shading to pale orange. It has good, clean foliage and is of free growth. Shown by Mr. Elisha J. Hicks.

Mary Merryweather.—Briefly this may be described as a paler Lady Hillingdon, for in everything except shade of colour it is very like that popular Rose, and so will be of great value on light and medium soils. The outsides of the petals are often delightfully sun-stained, and this harmonises well with the soft golden colour of the blooms. Shown by Messrs. H. Merryweather and Sons.

Mrs. Harvey Cant.—A large white H.T. Rose, very full in the centre, but when open the outer petals become somewhat loose, otherwise it would be a grand exhibition variety, but it should be of great value in the garden. Shown by Messrs. F. Cant and Co.

Mrs. Henry Bowles.—There can be no doubt as to the great claims of this splendid H.T. Rose to the gold medal, for it is practically everything that a gold medal Rose should be. It received the certificate of merit last year and was excellently shown several times later in the year. The beautifully pointed blooms are of great substance and

THE NEW POLYANTHA ROSE ALICE AMOS MIGHT BE CALLED A DWARF AMERICAN PILLAR.

of warm rosy pink colour lightly shaded with carmine. The outer petals are slightly rolled, and the blooms have a pleasant Tea fragrance. It should be a really good all-purposes Rose. Gold medal to Mr. W. R. Chaplin.

Mrs. Miguel Lacroze.—We are almost inclined to term this a "horrible example" Rose and to agree with the critic who said that from a little distance it appeared to be a Star Cineraria "gone mad." It was shown as a Wichuraiana variety, but is more probably a Polyantha. It forms compact trusses of medium-sized flowers which for a very brief time have magenta crimson borders to the dull white centre, and this colour soon becomes a horrible dull mauve-purple shade. Raised by Mr. William Mowlam and shown by Dr. M. Lacroze.

Pink Delight.—A really delightful free-flowering single Dwarf Polyantha Rose of the best wild rose pink colour and delicious Tea fragrance. It is of perpetual habit and recommended for pot culture and bedding purposes. Shown by Messrs. Laxton Brothers.

Ruth.—An all-purposes H.T. Rose of medium size, fully double and flattish shape. The bright golden yellow petals are heavily flushed with rosy orange and the petals have rolled margins. The foliage is neat and good. Certificate of merit to the Rev. J. H. Pemberton.

[Owing to pressure on space, report on the Nurserymen's and "basket" classes, and dinner table decorations has been held over until next week.—Ed.]

VEGETABLES ALL THE YEAR ROUND

Can I, as an amateur in gardening, grow vegetables to provide my family with a constant supply throughout the year? Yes, easily! provided that you have land, tools, seeds, brains, brawn and determination.

SINCE the art of gardening was first practised there have been learners, and they will come in their battalions as long as the world continues just as surely as the seasons will follow each other in their pre-ordained order. During the period that has passed, the question and answer above have been persistently repeated, and they will be asked and answered until the end of all things mundane. These words are written as a hint to growers of ripe experience that they need not read this article, as they regard it as a bounden, wise duty to read all others which appear in *THE GARDEN*, because it is not published to assist or benefit them, but to suggest to the novice the lines on which he ought to proceed to achieve his praiseworthy aspirations.

THE SIX NECESSITIES.

In the curt answer given above to the leading question which demanded it there are set forth six points, and it is essential that the aspirant to honours shall look upon them as real necessities. If a further question were asked to determine the order of importance there would be some slight change and we should find them running as follows: Land, brains, determination, tools, seeds and brawn, and while the first, fourth, fifth and sixth can be purchased or hired, the second and third must be provided by the individual. At the same time let it be said that the probabilities of supreme satisfaction are more pronounced when all the necessities are furnished by the individual, particularly so the brawn or muscle required to carry out the mechanical processes and which is, unfortunately, the one that is most commonly bought or hired, often perforce of circumstances over which the individual has no control. Without disparaging skilled hire in the smallest degree, one has not the least hesitation in affirming that the hired labour at the command of amateur gardeners is so far from being skilled that he who can provide the brawn to do all the work himself will find his chances of reaching his goal immeasurably improved, indeed, it may be said that the desired result is assured.

Land is placed in the forefront for the simple reason that without it brains and determination would be valueless; brains stand in the second position because they must be schooled to control all the other necessities, including the management of the land; and determination ranks third because obstacles and adversities are certain to be met and the firmest determination will be needed to overcome the former and to accept the latter in proper, philosophical spirit.

In addition to the necessities, there are accessories which are desirable without a shadow of a doubt, but their absence is not so great a desideratum as to compel one to accept the supposed fact that success is impossible of achievement. For instance, a greenhouse and one or two frames will render the task an easier and surer one, but if they are not present they can be done without they are not, then, necessities. And the same might be said of other things, but it would serve no useful purpose to enumerate them and would, therefore, lead to waste of space.

THE TIME TO START.

The actual time of commencing on our interesting, health-giving and food-producing work is not of substantial moment. There is something to be done in every month, aye, every week, of the year,

but December and January will usually be found the least favourable, though much may be done then by those who grasp instantly the opportunities that the variations of the weather afford, with October and March as the most favourable since then much positively must be done, no matter whether one is working in an established garden or is setting out upon the great task of making a new one. However, we find ourselves in July with its seasonal duties, and this month shall be, therefore, our base, and our object the production of vegetables for autumn, winter, spring and early summer. In many gardens the only seed of substantial importance sown in July is Cabbage to yield cuttings in spring and summer of next year, but there are many other kinds which demand recognition during this month and August, as will be shown in a later paragraph.

AREA OF LAND REQUIRED.

The size of the garden is generally rigidly governed, but were it not so it would be impossible to define a rule stating the area necessary to supply a family with vegetables all the year round. It is obvious that the number in the family must be a governing factor, and, further, the capability of the cultivator must have close consideration, since all of us who are familiar with amateur gardeners know that there is a man here and there who will produce double the quantity of excellent produce that his neighbour will do, notwithstanding that they may be working under identical conditions of soil and other natural conditions. Then, again, some soils have infinitely greater latent capacities than have others, and the man who finds the way to draw these out to the utmost limit is clearly in a superior position to the man who fails so to do.

Speaking in the broadest sense one would regard 10 rods devoted exclusively to vegetables as the minimum area, but this will not be enough for a large, growing family, because it will be impossible to find space for a sufficient bulk of keeping Potatoes. Early or new Potatoes will be a simple matter, and space will be available for all other kinds; but the weight of Potatoes demanded by a family of, let us say, six persons, including four well on the up grade, is surprisingly large and cannot be managed in the area specified. The amateur who has 15 rods to 20 rods of cultivable, naturally suitable land ought to be able, and indeed will be able, to produce an ample sufficiency for ten or twelve people; if he has to cater for a bigger number the chances are that he will deem it wise to place at least a proportion of the mechanical labour in the hands of someone else, and immediately he is compelled to take this course he will find that his return to the square rod will fall by from 20 to 30 per cent.

JULY AND AUGUST OPERATIONS.

Since it is obvious that there must be a "carry over" from one year to another in the crops of a garden, no matter in what month a start is made, we shall appropriate to ourselves the early Potatoes, Peas, Onions, Carrots, Cauliflowers and other kinds which are coming on, and plant next spring to provide at least equal compensation to the succeeding season. By taking this step we shall have the advantage of the seedlings of Winter Green vegetables sown at some date between March and the middle of May, and all of which can be successfully planted out during the present month and August.

The Borecoles, Savoys and very late Brussels Sprouts (if there are any) will be allocated to a piece of ground that has been cultivated to its utmost depth and which is known to contain a plentiful supply of readily available food; showery weather will be chosen, if possible, and failing it the immediate sites to be occupied will be heavily soaked with water on one evening and the plants will be moved to them on the following day, packing the soil firmly to the roots, which should go in undamaged. It is not much trouble and always good policy to draw the roots through a thick sludge of soot, lime, soil and water, for it may arrest subsequent enemy visitations and invariably aids establishment.

Sprouting Broccoli and also those flowering varieties to come in by the middle of December must be treated in the same manner, but varieties of the latter for use from midwinter onwards to late spring should be planted on the autumn Onion bed or on the site of a grubbed Strawberry plantation, neither being prepared in any other manner than by hoeing completely to remove every weed. A handfork or a trowel is far better than a dibber for planting as a general rule, but the later sorts of flowering Broccoli should always be bored for, and preferably with an iron-shod tool, and the soil must be packed to them just as hard as the surrounding level, the direct object being to encourage so sturdy, stocky, hardy a growth that it will not succumb during very bad weather, as much too frequently happens with plants set out in the ordinary way in well worked ground. Between the middle of July to the end of August seeds of many kinds can be sown with excellent prospects of success, but perhaps we ought to regard Cabbage for spring as the most important, since it is unquestionably one of the most highly favoured of all vegetables. There are many varieties from which choice can be made, but the seeds must be bought from an absolutely reliable source, or it is well within the bounds of possibility that more than half the plants will run to seed instead of forming hearts. If it can be managed, some flaky material, such as leaf-mould rubbed through an eighth of an inch riddle, should be incorporated in the top 8 ins. of the seed beds, as the roots of the seedlings will cling to it very tenaciously and easy, certain transplantation is then practically assured. Distribute the seeds very thinly in drills about half an inch deep and 6 ins. asunder and cover in with fine mould. Given thin seeding, little thinning out will be demanded, but what is necessary must be commenced directly the youngsters are big enough to handle; a second sowing of seed should always be made three weeks after the first to ensure that there shall be plants so thrifty and sturdy that they may be relied upon to pass through the winter in perfect safety.

In the case of a garden which was planned out early in the year it is doubtful whether there will be much space available, but in no circumstances ought a row or two of a dwarf, naturally fast-podding Pea to be omitted, while one or more rows of a Dwarf French Bean will give welcome pickings in due course. There will have been legislation for a bed of an early Carrot, which will give many sweet dishes later on and there is no danger of losses owing to the fly. The Carrot ought to go in before the end of this month, but rather than miss them sow in August, and add such salad vegetables as Radishes, Lettuces and Mustard and Cress; autumn Onions, Turnips, Beetroots, if they are especially desired; Spinach in two sowings, one at the middle and the other at the end of the month; and Perpetual Spinach or Spinach Beetroot, which will give a green dish in spring when everything else fails. W. H. LODGE.

MANY INTERESTING NOVELTIES AT VINCENT SQUARE

THE new plants were the centre of attraction at the R.H.S. Hall on June 27 when, as well as many awards of merit, two first-class certificates were awarded. In addition to the beautiful vase of *Rhododendron discolor* from Kew, many trusses of this Chinese species were shown by Dame Alice Godman, and these illustrated an interesting variation in the seedlings. In the Horsham collection the colours ranged from an almost paper white to nearly the pink of Pink Pearl, and all were very beautiful. Besides this colour variation the fragrance seems elusive; some trusses possessed the gift, which was absent in others. A similar thing occurs at Kew, where two specimens grow side by side. The flowers of one are deliciously fragrant, while the other bears scentless blossoms. The species seems to be quite hardy, but shade from direct sunshine is essential. Dame Alice Godman also showed sprays of the elegant white-flowered *Styrax Wilsoni*.

Other interesting shrubs included a good batch of *Kalmia latifolia* by Mr. T. Lewis, who told us that these were some of the bushes that Queen Mary admired so greatly at Ascot and commanded a dinner-table decoration to be made of cut sprays from some of them.

Mr. Charles Turner had some beautiful varieties of *Philadelphus*, and also sprays of *Tilia asplenifolia*, *Ligustrum Ibota* in full bloom, *Ochna*

multiflora and *Neillia (Spiraea) Torreyi* bearing a quantity of their interesting fruits.

Border flowers were shown in great abundance and of much better quality than might have been expected considering the long drought. *Delphiniums* predominated and were represented by wonderfully fine spikes of all shades of blue and many of mauve. In Kelway's collection the very best was James William Kelway, which has very large, white-eyed, dark purple flowers. *Smoke of War* was also very striking, while of their pale blues the best were Gaby Deslys, Sir Alfred Keogh and Geraldine Kelway. Of the many *Delphiniums* shown by Messrs. Blackmore and Langdon, *Dusky Monarch* and Robert Cox of the dark sorts and Queen Mary, Mrs. Townley Parker and

were a couple of very desirable Giant Thrifts. *Verbena chamaedryoides* in a collection by Messrs. Waterer, Son and Crisp was dazzling in its scarlet colour, but it is, unfortunately, not quite hardy, though well worth the trouble of wintering in a frame.

A pretty water garden was made by Messrs. Hillier and Sons, and it was surrounded by many

THE HUGE AND BRILLIANT ANEMONE GLAUCOPHYLLA.

THE BRILLIANT BLUE DELPHINIUM MRS. F. T. NEIGHBOUR.

Queen of Bath of the paler blues were very charming. Messrs. R. H. Bath, Limited, and Mr. W. Wells, Jun., also had many beautiful *Delphiniums*.

The first herbaceous *Phloxes* of the season were displayed by Mr. H. J. Jones, who had excellent plants in 5in. pots. The most noteworthy sorts were Homeland, H. J. Jones, Florrie Freeman, Selma and John Meakings.

Of other border flowers the garden Pinks shown by Messrs. B. Ladhauns, Mr. Clarence Elliott and Mr. M. Pritchard were very beautiful. *Oenothera speciosa grandiflora* was also excellent, and in *Armeria cephalotes gigantea rubra* and *A. Bees Ruby* there

was suitable plants. In the pool there was a selection of such good *Nymphaeas* as Gladstoniana, Escarboucle, *Mariacea chromatella*, and *atropurpurea*. A tall bush of *Hydrangea Sargentiana* was handsome in its large woolly leaves, and was well set up with flower-buds. Messrs. William Cutbush and Son had a well designed little rock garden which would be suitable for a garden of quite modest dimensions.

English Irises were largely shown by Messrs. Barr and Sons, who had a large number of excellent named sorts. Messrs. Cheal and Sons also had English Irises and, like Messrs. Carter Page and Co., also showed some early *Dahlia* blooms. With *Delphiniums* and many other border flowers Messrs. G. Bunyard and Co. staged brilliant spikes of *Iris Monnier* and *I. ochroaurea*.

As though in anticipation of the Regent's Park Rose Show later in the week, Mr. William Paul, Messrs. Frank Cant and Co. and the Rev. J. H. Pemberton had good collections of *Roses*.

Collections of greenhouse *Carnations* were staged by Messrs. Allwood Brothers and Mr. C. Engelmann, while Mr. James Douglas had some of his splendid Border varieties, of which the rich yellow *Sunshine* found many admirers.

A very large collection of *Sweet Peas* was delightfully arranged by Messrs. Sutton and Sons,

who shewed generous quantities of such valuable sorts as Picture, Gladys, Orange Perfection, Doris, Hawlmark Pink, Adelaide, Mrs. Tom Jones and Doris Usher. Messrs. R. Bolton and Son again shewed fine blooms of Comrade Tangerine, Elsie Dene and Tangerine Improved.

Stove plants were more numerous than usual, and Messrs. L. R. Russell, Limited, had a splendid collection, including Pitcher plants, Crotons, *Medinilla magnifica*, *Dracenas*, *Clerodendron Balfouriana* and *Tabernaemontana coronaria*. A large number of *Caladiums* and good plants of *Streptocarpus* were shewn by Messrs. J. Peed and Son. An excellent strain of *Streptocarpus* was displayed by Messrs. R. and G. Cuthbert. A magnificent amateur collection of Crotons was arranged by Mr. J. W. Barks, gardener to Mr. A. P. Brandt, Bletchingley, Surrey. These were all splendidly grown and beautifully coloured. Messrs. Bastin and Son again shewed some of their admirable double-flowered tuberous *Begonias*, and with many other sorts included the beautiful salmon-tinted variety *Lady Bell*, for which they received an award of merit at the previous meeting, though it was erroneously attributed to another exhibitor. Mrs. W. Churchill, Mrs. W. Wilson and *Lady Diana Cooper* are also splendid sorts.

The only fruit exhibit was a large collection of heavily fruited pot Cherries by Messrs. T. Rivers and Son. The varieties included the new *Peggy Rivers*, *Elton*, *Early Rivers*, *Governor Wood* and *Frogmore Bigarreau*. From the *Wisley* trials the R.H.S. sent up plants of the *Broad Beans* to which the sub-committee had given awards of merit on the previous day. The plants were all heavily fruited, the varieties being *Bunyard's Exhibition*, *Broad Windsor Selected*, *Champion Longpod*, *Green Leviathan*, *Selected Hang-down*, *Shirley Longpod*, *Multiple*, *Improved Giant White Wonder* and *White-eyed Early Large*. Messrs. Sutton had pot plants of new dwarf types of *Broad Bean* obtained by crossing Sutton's *Longpod* with *Beck's Green Gem*.

NEW AND RARE PLANTS.

Anemone glaucophylla.—This was decidedly the "flower of the show," and if a popular name is needed, might well be termed the *Clematis-flowered Anemone*. Unfortunately, it is a tender species, otherwise everyone with a garden would wish to grow it. As the plant on view was grown under glass, it is just probable that the branching flower-stem was slightly drawn, but it was almost 3ft. high and bore a large, nearly round, five-petalled bloom of glistening satiny mauve colour and fully 5ins. across. The stout, glaucous, pinnatifid leaves have rather long, hairy stalks, and form a rosette about 2ft. in diameter. It is one of Mr. Forrest's introductions. First-class certificate to Colonel Stephenson Clark.

Rhododendron discolor.—This fragrant and handsome Chinese species has already received an award of merit, and now has the highest award. The large, compact trusses were composed of big, nearly white flowers, which have pretty, slightly crimped margins. At Kew there are two large bushes in full bloom, and they are exceedingly decorative. First-class certificate to the Royal Botanic Gardens, Kew.

Pink Prichardii Donnicketti. A brilliant, free-flowering little garden Pink. The outer parts of the petals are stippled with rich crimson, and there is a broad maroon zone. Award of merit to Messrs. M. Prichard and Son.

Æsculus indica.—The beautiful Indian Horse Chestnut is comparatively rare in gardens. It is a native of the North-West Himalayas, and quite a hardy tree. In its native habitat it attains a height of 100ft. At Kew a small tree near

the glasshouses (T range) is particularly beautiful just now. The erect panicles are between 12ins. and 18ins. long, and more cylindrical than those of the common species. The flowers are milk white in colour, and the shorter pair of petals have a rosy carmine blotch at the base. The large shining deep green leaves are very handsome. Award of merit to the Royal Botanic Gardens, Kew.

Begonia Aurora.—An ideal double-flowered tuberous-rooted *Begonia* which will probably be equally as good for summer bedding as for pot culture. The perfectly shaped flowers are of rich yellow colour very lightly edged with rosy apricot, which shading also appears on some of the older petals. Award of merit to Messrs. Blackmore and Langdon.

Begonia Eunice.—A very charming and floriferous basket *Begonia*. The pendulous flowers are of a soft pink shade. Award of merit to Messrs. Blackmore and Langdon.

Begonia Stella.—This is another beautiful and floriferous basket *Begonia* and of vivid rosy cerise colour. Award of merit to Messrs. Blackmore and Langdon.

Begonia Venus.—Yet another lovely and free-flowering basket *Begonia*. This is of milk white

staging accurate inspection was impossible, but from what we saw the specimen seemed more like *Cornus Nuttallii* than *C. capitata*, which is the newest name for the sub-evergreen tree known as *Benthamia fragifera* in Cornish gardens, where it is so much at home as often to reproduce itself from seed around the parent. In Cornwall it is mostly prized later in the year when loaded with its crimson seeds, and is often known as the Strawberry Tree. The "flowers" are really bracts, the true flowers being minute and crowded in a more or less circular mass. Award of merit to Mr. E. J. Lucas.

Delphinium Decorator.—This highly decorative variety might well have received an award even though the centre spike was over. It has a freely branching habit. The individual flowers are smallish, semi-double, star-shaped and of intense blue colour. Shown by Mr. F. W. Smith.

Delphinium Mrs. F. T. Neighbour.—A very beautiful spike of large, handsome blooms. They are of sky blue colour lightly flushed with dull mauve towards the centre, which has a white eye. Award of merit to Mr. F. W. Smith.

Gaillardia Knight Errant.—A round, well formed bloom of rich yellow colour with a

THE SILVERY WHITE MOCK-ORANGE, PHILADELPHUS COUPE D'ARGENT.

colour lightly flushed with apricot at the base of the petals. Award of merit to Messrs. Blackmore and Langdon.

Buddleia alternifolia (See page 292).—When shown by Sir Harry Veitch at the previous meeting we greatly admired the long, graceful sprays of silvery lavender flowers, and were surprised that it failed to receive recognition, and since then we have seen large bushes in flower which increased our opinion of its merits. Award of merit to Mr. Lionel de Rothschild and the Hon. Vicary Gibbs.

Campanula rotundifolia Jenkinsii.—This elegant and free-flowering variety was one of the many plants of merit raised by the late Mr. E. H. Jenkins, who for many years contributed such admirable articles on hardy flowers to THE GARDEN. *Campanula Jenkinsii* is a delightful plant for the front of the flower border or for the lower parts of the rock garden, where its erect, slender spikes of numerous white, bell-shaped flowers would be effective. Award of merit to Mr. H. J. Jones.

Carnation E. G. Quick.—A border *Carnation* of good shape and uncommon colouring which may perhaps be described as a dark slaty heliotrope. Award of merit to Mr. James Douglas.

Cornus capitata.—The sprays had flagged so badly that in the congestion near the new plant

small, distinct scarlet zone. Award of merit to Mr. G. R. Downer.

Gaillardia Yeoman.—This is apparently from the same strain as the above, as the colouring is almost identical, but the flower is larger and has more pointed petals. Award of merit to Mr. G. R. Downer.

Philadelphus Coupe d'Argent.—The silvery white, chalice-shaped flowers are over 2ins. across and have a fascinating touch of pale rosy lilac at the base which suggests *roseo-maculatus* parentage. The blooms are freely borne on graceful sprays, making it a charming and desirable variety. Award of merit to Sir William Lawrence.

Rose Jacqueline.—A very beautiful Briar Rose. It is a full-petalled single Rose of bright rose pink colour with golden yellow at the base of the petals and a nice cluster of golden stamens. It appears to be a very free-flowering variety. Award of merit to Messrs. William Paul.

Cherry Peggy Rivers.—This seedling dessert Cherry is much like *Governor Wood*, but, unlike that sort, the fruits do not split, and this was the chief reason for the award. The seed parent was stated to be *Bigarreau Gros Cœur*, and it has a sweet flavour. Award of merit to Messrs. T. Rivers and Son.

CORRESPONDENCE

THE YELLOW WOOD.

THAT handsome tree, *Cladrastis tinctoria*, has blossomed very freely at Kew during the present summer, though usually few flowers are produced. A native of the south-eastern United States, the Yellow Wood forms a large-headed tree up to 60ft. high, with handsome pinnate leaves 9ins. to 12ins. long, composed of, usually, seven or nine large oval leaflets. A peculiarity of the leaves is that the base of the leaf-stalk is swollen and covers the axillary bud in the same way as the Plane. The white, pear-shaped flowers are borne in pendent panicles 9ins. to 1ft. long, from the points of the shoots, which remind one of *Laburnum* inflorescences of white flowers. Although the tree does not flower regularly, it is worth growing for the sake of its ornamental leaves, which turn to an attractive golden hue before falling. The wood of this interesting tree is bright yellow, which accounts for the common name.—W. L.

THE PERPETUAL-BORDER CARNATION.

I WAS much impressed at York Gala with the Perpetual-flowering Border Carnations in Messrs. Allwood's exhibit. These were shown in larger quantity and greater variety than before. This type, if it upholds its present promise, is destined to make a name, and if it prove as hardy as the old Border Carnations and more free-flowering, will make the latter look to its laurels. As regards hardiness, Mr. Edward Allwood assures me that the plants have stood the test of the last three winters unprotected on cold, clayey soil in Sussex, and I have found them quite as hardy as the ordinary Borders during the past winter. Still, I should like to grow them through another winter before arriving at a definite decision as to their absolute hardiness. In beauty of form, soundness of calyx, colouring and fragrance, however they are superb, and of the varieties already in commerce the self shades of purple, cerise, rose, crimson and maroon are very fine, and the daintily marked kinds, such as Highland Lassie, Sussex Maid and Sussex Perfection are as pretty as any of the Picotees. New colours are being evolved. I am growing for trial many beautiful scarlets. There is a variety almost identical in colour with the famous Edward Allwood, several shades of red, a rich vermilion, and quite recently there appeared in a batch of seedlings the first pure yellow, exactly similar in colour to Border Yellow, but larger and of finer form.—NORMAN LAMBERT.

AEROPLANES AND INSECTS.

I WAS "vastly intrigued," as writers in the newspapers so picturesquely put it, by the story of an aeroplane attack on myriads of caterpillars in a fruit plantation in Kent. The whole idea of pitting the august aeroplane against the insignificant insect opens out immense and far-reaching possibilities. One ventures to think that after the remarkable success of the present experiment—there was scarcely a live caterpillar left after about half an hour's dressing—the old-fashioned methods in which petrol, paraffin, horse and man driven appliances with liquid dressings are employed will be hopelessly out of date in a short time. Manufacturers of such-like machinery will be directing their abundant energies towards the production of aeroplanes fitted with apparatus for distributing powders, and mayhap liquids, that will destroy all the "bugs" to which the fruit and vegetable crops of the country are heir; horticultural chemists will spare no intensive efforts to provide

compounds which, containing no arsenic or other poison, cannot possibly involve risk of injury to any other form of life than insect enemy; while entomologists will direct their scientific attention to the education of these insects to the end that coming generations shall do most, if not all, of their feeding on the upper surfaces of the leaves and twigs instead of, as now, seeking positions where they are effectually screened from above and by no means easy to reach from below, even by skilled men working actually beneath the branches. One must confess to a strained feeling at the thought of clouds of arsenical or other poisonous dusts floating about in the atmosphere,

THE FINE RHODODENDRON CYNTHIA IN A TUB.

which, if they will not kill off odd superfluous members of the animal kingdom, will undoubtedly "make 'em sneeze a bit." By the way, the firm which fitted the distributing apparatus to the aeroplane used ought to get a good advertisement out of it, or perhaps the half ton of stuff was pitched out by the bucketful!—W. H. LODGE.

THE KENTUCKY COFFEE TREE.

THOUGH a distinctly ornamental tree, the Kentucky Coffee (*Gymnocladus canadensis*) is by no means common in our gardens. In view of this it is particularly interesting to find a tree flowering in a comparatively small garden at Kaybough, Kew Gardens Road, Kew. Purchased when the tree was twenty-two years old from a Kingston nursery in 1878, and planted in its present position by the late Mr. Charles Wright, it is now approaching 60ft. in height. The tallest tree in the British Isles is said to be the specimen at Claremont 60ft. in height. As a rule the trees of the Kentucky Coffee are dioecious, the tree flowering at Kaybough being staminate. More

interesting than attractive from a floral standpoint, Mr. W. J. Bean describes *Gymnocladus canadensis* in his book as: "In its foliage perhaps the most beautiful of all hardy trees." Mr. Wright's daughter, Miss Wright, the present owner, is justly proud of beautiful specimens of *Taxodium distichum* (which produced cones freely last year), *Ginkgo biloba* and *Ailanthus glandulosa* planted at the same time.—A. O.

RHODODENDRON CYNTHIA.

I AM enclosing you a photograph of a *Rhododendron Cynthia* which I had when it was very small thirty-five years ago and have grown in a tub ever since. It had 335 trusses all in perfect condition. The photograph was taken for me by the Photocrom Company, Limited, and I thought the picture might interest your readers.—M. M. SAMUEL.

[The picture well illustrates the value of *Rhododendrons* for the town garden and the beauty of that grand old variety *Cynthia*, which has vivid deep rose flowers. In an article on another page, Mr. Gomer Waterer calls attention to the merits of many of the old hybrids which are not now being planted to the extent they should be.—ED.]

"AFFECTED" GARDENS.

A RECENT visitor who knows naught of "Anne A.," but is herself a very keen "amateur" gardener, remarked to a mutual friend (who was taking her round my garden and gathering a "country garden" posy for her *en route*) "I do like this garden; it is so quaint and simple and unaffected." I—lying low—overheard, and it set me wondering.

Are some of our modern carefully planned gardens "affected"? Will the next generation jeer at and despise them as we mostly scorn Victorian "bedding" borders (though there are some places—public parks and the like—where I think "bedding" seems right)? It's really rather an appalling idea, isn't it? I myself am much in love with little "formal" gardens informally planted, especially for town and small villa gardens, where the little "lawn" is nearly always more or less a miserable, threadbare failure. Pondering the matter and thinking of the most delightful gardens I have known, I must own they were *not* "planned" all at a time, but grew bit by bit as fresh ideas and "wants" occurred to their owners. Can it be possible that our present-day up-to-date "planned" gardens (awful thought!) are akin to those rooms full of "period" furniture, which never please me, showing, as they generally do, such a lack of originality, courage and individuality in their proprietors and recalling all too vividly the "showrooms" of large furniture shops?—ANNE AMATEUR.

IRIS NOMENCLATURE.

AT the Iris Conference held at the R.H.S. meeting on June 7 one of the points raised was the desirability of the regulation of Iris names. This was emphatically advocated by almost every speaker. Mr. Dykes, Mr. Wister, M. Mottet and others agreed that the duplication of names was to be strongly deprecated, and various suggestions were made for the purpose of ensuring that in the future no new Iris should be sent out under a name that has already been used. The American Iris Society have compiled a list of names under which Irises have been distributed from time to time, and it was proposed that the English and French raisers should so far as possible consult this list and make it a basis of a permanent record, so that duplication should not occur in the future. On opening THE GARDEN for June 24 the necessity for some such arrangement becomes very apparent.

In 1914 we received at Colchester some plants from M. Denis of Balaruc-les-Bains under the name Iris *Ochracea-cerulea*. This variety was shown by Mr. W. R. Dykes on June 7 and received the award of merit. According to THE GARDEN, someone has now decided to rechristen this variety "Sunset." In the first place, has anyone other than the raiser any authority for altering the name given by him to one of his productions? Secondly, if it was considered necessary to alter the name, surely some suggestion would be made by the Floral Committee of the R.H.S. when considering the flower for award, and the natural course would be for them to certificate the plant on its merits with the suggestion that the raiser be consulted regarding the alteration of the name. As far as one can gather, no suggestion of this sort was made. Thirdly, on referring to the Check List published by the American Iris Society, I find there is already an Iris registered by the Society under the name of Sunset. If therefore this Iris, after having been in existence in English gardens for eight years as *Ochracea-cerulea* and having been certificated by the R.H.S. under that name, is now to have this name changed in such a casual manner, nothing but confusion can be the result, especially if the substituted name is that of another Iris already in cultivation. It is certain that some firms will adhere to the only name to which it is at present entitled, and we shall therefore have this variety being distributed to the public under two distinct names, one of which is already borne by another variety.

There is also a slightly misleading statement in the same issue of THE GARDEN, namely, that it is "to be distributed this autumn." As it was in cultivation in England in 1914 and registered by the American Iris Society as having been distributed in 1919, this statement is a little misleading.

Certainly *Ochracea-cerulea* is cumbersome and somewhat misleading. The first thought it conveys to one hearing the name for the first time without seeing the plant is that it may have something to do with two species or varieties that have nothing to do with the section to which it belongs. For instance, Baker gives the variety *Ochracea* of Regel as a form of *I. iberica*. I notice even the American Iris Society seems to have lost sight of this fact, as it has registered the name of this tall bearded variety in its "standardised plant names" as *Ochracea*. It may be that in the effort of the Society to eliminate double-barrelled names it has unconsciously erred in the duplication of varieties under the same name.

Certainly something definite and authoritative would seem to be necessary, and if the name is to be altered it should be done in such a way that the new name can be universally accepted as correct. In the meantime we have only one authoritative name for it, and that is the one

under which it was certificated by the R.H.S. and introduced by the raiser.—GEO. DILLISTONE.

IRISES FOR TOWN GARDENS.

I AM sending you a photograph of the Iris walk in this garden in case you care to reproduce it. The Irises were planted two years ago; this is their second year of blooming. They are very fine—all up-to-date varieties—and were supplied by Messrs. Whitelegg and Co. and Messrs. Waterers. I think you may care to shew what can be

AN IRIS WALK IN A TOWN GARDEN.

done with Irises in a town garden.—CHARLES H. RICE, *St. Albans*.

A REPROACH TO THE LAND.

RETURNING from France the other day I spent a few days at Folkestone for the first time, expecting to see something of the flowery beauty of Kent, "the Garden of England"! So I duly explored the walks under the Lees and the partly planted paths near the sea as far as Sandgate. Here and there where the natural wild growths of the undercliff still remained there are oases of grass and wild flowers, such as *Convolvulus arvensis*, where some charm still lingers. But what shall I say of the rest? Shall I be believed, I wonder, if I say the rest is simply a wilderness of asphalted paths, *Euonymus* and *Privet* bushes, with here and there a garish patch of wild Mustard or a flourishing colony of Nettles? It is not possible to exaggerate the poverty, the misery and the neglect of the so-called gardens on this strip of South-east Coast, where surely something attractive might be made. At some period a certain quantity of Pines and Sycamores have been planted which present the most sorry sight. Never did I see so many half-dead trees and shrubs, never did I see such a deadly uniformity of stunted Pines and Sycamores. The latter were in a few cases green and flourishing in leaf this fine season, but even many of these have half-dead tops and dead branches that are most disfiguring and depressing! Underneath, in their shelter, I looked for at least a few flowering shrubs to diversify the bare earth, but *Privet* and *Euonymus* alone rewarded my search. I will admit there are some Elder bushes occasionally

and I did see one very miserable *Aucuba*, but not one of the most useful and indispensable seaside shrubs is to be seen, only bare earth and asphalted paths and wide roads! Are the Kentish gardeners and authorities aware how deadly dull and unattractive they have made their seaside walks? Have they never visited other places where the cliff sides are a mass of attractive shrubs and bright flowers that need little attention from year to year? Is Folkestone so much more exposed to bitter sea winds than

other places that it cannot produce a single flower or pretty shrub that shall catch the eye of the seeker after sunshine and beauty? To judge by its so-called gardens, Folkestone must surely be the coldest and most wind-swept place in the British Isles! There is not an *Escallonia* bush, not even a *Veronica*, so very ubiquitous in most seaside places. Not even the hardy and decorative *Olearia Haastii* is to be seen anywhere, nor did I see a *Laurustinus*, or even a *Laurel* or *Bay Tree*. In private gardens by some villas an *Hex* or two shewed what might be done, but as a rule Elder bushes, wild Mustard and Nettles held undisputed sway the whole length of these dreary asphalted roads.

Accustomed as I am to the *marvellous* (and I say it with intention) gardens that are to be found on our coasts elsewhere, to say nothing of those in other lands, I think the Men of Kent should rise up in arms and demand that one of the principal passenger ports of England should shew a more attractive face to its many visitors. Let them go to see what is done elsewhere, and if they do not return fired with the desire to mend their ways, they will deserve the reproaches of all men who love their fair country. As an instance of what has been done on an exposed coast, let them go to Scarborough, where there are literally miles of gardens planted on the cliffs, rich in Roses, in trees, in flowering shrubs, and many a flowery path down to the sea. Surely Folkestone can do as much, and rival, if not surpass, the northern gardens that are so very carefully ignored in the advertisements so liberally distributed in all parts of the kingdom. Let it be no longer deserving the name of the Land of Neglect!—E. H. WOODALL.

GARDENING OF THE WEEK

FOR SOUTHERN GARDENS.

The Kitchen Garden.

Early Potatoes.—Where these are ready for lifting and are occupying ground in demand for crops of Turnips, etc., they should be lifted and removed to a cool store. If it is decided to keep any for seed purposes, they should be spread out singly so that they may thoroughly mature before being removed into storage.

Shallots.—As the foliage turns yellow and shows signs of decay the roots should be lifted, and after a thorough drying and ripening in the sun, the bulbs stored in a cool, dry, airy room.

Runner Beans.—If the weather proves hot and dry during the early cropping days of these Beans, the plants will derive immense benefit by several copious syringings and waterings, preferably during the evening. Follow this up with a mulching of well rotted manure if possible, or if this cannot be arranged keep the ground lightly hoed to prevent caking of the surface soil and to prevent a too rapid evaporation.

The Flower Garden.

Biennials sown some few weeks ago should be pricked out as soon as convenient, especially if the sowing was done thickly. It is not advisable to put the young plants out into a too rich compost, as growth made under such conditions is not of the best for withstanding hard weather later on. A site having a little shade during the middle of the day is the best for Canterbury Bells, Forget-me-nots and Aquilegias, and all rows should be spaced so that the hoe can be frequently plied between them.

Crocuses.—Where these are appreciated corms of the autumn-flowering and winter-flowering kinds should be planted as soon as possible. By a careful selection of varieties flowers may be had almost continuously from August until March, but unless the positions chosen for some of the winter-flowering ones are somewhat warm and sheltered, unfavourable climatic conditions will soon mar them. One of the best and most reliable autumn-flowering kinds is *C. speciosus*. As a general rule Crocuses like shallow planting, but it will be found better to plant this variety rather more deeply.

Bulbs in Grass.—If not already scythed over, the foliage of these, which looks somewhat untidy, should receive such attention. This operation will also give sun and air an easier access to the bulbs.

Fruit Under Glass.

Late Grapes.—Careful thinning is more important in late vineries than in any of the earlier houses, chiefly because of the necessity that all berries should be allowed proper room for development and to ripen thoroughly, without which it is almost impossible to keep them in a satisfactory manner. Attend to the stopping and regulating of the growths as necessary, and endeavour if possible for all late black Grapes to have a regular covering of foliage over the house, but avoid too dense a covering for late white ones. Should the Vines show any signs of exhaustion by feeble growths or unsatisfactory swelling of the berries, make doubly sure that overcropping is not being carried out. This and root dryness are the Vine's most deadly enemies, and although such errors of culture are rarely met with among growers of experience, they are probably the beginner's most common mistakes.

The Hardy Fruit Garden.

Late Strawberries will need some assistance following the severe tax which has been placed upon the plants by the early drought and great heat and by the most unfavourable period of growth after cropping last season. Where it can be arranged to give the plants a couple of thorough soakings with weak farmyard manure, it will be well repaid, and it will be also advisable to reduce the number of fruits upon heavily set trusses. The layering of late varieties should be proceeded with as suitable runners become available.

General Work.—Attend as necessary to the protection of Gooseberries, Currants, Raspberries, etc., and if not already done, see that all superfluous shoots are removed from the Raspberry plot. It may be well also about this time to examine any trees which may have been grafted

this spring and ascertain whether the tying material is doing any damage.

H. TURNER
(Gardener to the Duke of Northumberland).
Albury Park Gardens, Guildford.

FOR NORTHERN GARDENS.

The Kitchen Garden.

Asparagus Beds.—It is most important that the beds be kept free from weeds and the tall growths supported, otherwise the Asparagus tops may be much shaken by strong winds, and when the growths get broken the roots suffer. On light soils a moderate sprinkling of salt should be given, also occasional applications of liquid manure.

Brussels Sprouts.—It is most essential that the soil between the rows of Brussels Sprouts should be well cultivated so that a quick yet sturdy growth be encouraged. In gardens where the soil is poor an application of a reliable artificial manure should be dusted over the roots during showery weather. On gravelly soils mulchings of short rotted manure should also be given, otherwise it is almost impossible to produce the fine firm Sprouts so desirable to the grower of this popular winter vegetable.

Cucumbers.—Make a sowing now so as to obtain plants for late planting so that the production of fruits may be ensured as far on in the season as possible. Like early crops, the latest supplies always seem to be much appreciated. Sow a prolific and free-setting variety, such as Cardiff Castle or Austin's Improved Telegraph, which is specially recommended for late cropping.

Spinach.—Sow a few lines of the ordinary round variety on ground that has been cleared of early Potatoes. As the season advances fresh pickings are esteemed and late sowings do not so readily run to seed.

Vegetable Marrows.—Thin the growths of Marrows where the plants are likely to become overcrowded and water regularly during dry weather. Cut the Marrows when large enough so as to allow the later fruits more chance to develop.

Milan Turnips.—Continue to sow at regular intervals a few lines of Purple Top or Early White, as in most establishments this type is much favoured.

The Hardy Fruit Garden.

Raspberries.—Look over the Raspberry plantation and remove all weak or superfluous shoots, retaining only sufficient of the strongest for next season's fruiting.

Strawberries.—Where quantities are required for forcing purposes the necessary number of layers should be secured without delay. Layer the runners into 2 in. pots, plunging the pots to the ground level. Immediately root action commences pinch out the growing point beyond the pot containing the layer. Should dry weather intervene, watering must be attended to, as the soil in the small pots will dry up quickly.

Summer Pruning.—This important treatment in regard to fruit trees should now receive attention, for by the timely removal of surplus shoots the fruit gets a much better chance to swell and ripen. Summer pruning is also of considerable assistance in maturing the spurs for future crops. The formation of young trees can also be much improved by the judicious removal of all superfluous growths and the stopping of the remaining shoots.

The Flower Garden.

The Rock Garden.—It is necessary to go over the rock garden occasionally to prevent the encroachment of the strong-growing plants on the weaker sorts. The want of this attention often results in the loss of many of the smaller and more choice plants. Many rock plants can be propagated freely from cuttings at this time, while others should have small rooted portions potted up and placed in a cold frame in readiness to fill the blanks that may be caused by severe climatic conditions or by the ravages of slugs.

The Shrubbery.

Newly Planted Shrubs.—Much anxiety is often caused during lengthy spells of dry weather owing to the wilting of small trees and shrubs planted during the spring. Where at all possible, heavy waterings should be given late in the afternoon, so that the roots may have the cool of the

evening to absorb the moisture. A thick mulching of moss litter is also of considerable benefit in creating a cool root-run, while lawn mowings as a surface mulch should not be despised at this time.

JAMES McGRAN
(Gardener to Sir Henry H. Houldsworth, Bart.).
Coodham, Kilmarnock.

CONSERVATORY AND GREENHOUSE.

Mimulus glutinosus is an old greenhouse plant which is seldom seen at the present day. The type plant has rather small flowers, and generally has been superseded by the improved varieties Sunbeam and coccineus, both of which are sometimes used for summer bedding. They are all easily propagated at any time by means of cuttings of the young shoots, which should be placed in a close case in a cool house. If propagated at this time they will make nice flowering plants for next summer. They are easily grown at all times in an ordinary greenhouse.

Calceolarias.—Seed of the herbaceous type should now be sown in a cool greenhouse. The seed-pans should be watered some time before sowing, as the very fine seed should only be covered with the finest sprinkling of sand. If the seed-pan is covered with a pane of glass and shaded, no further watering should be needed until the seed germinates. If watering is necessary, the seed-pans should be dipped in a vessel of water. Calceolarias of this type require cool and moist conditions at all stages of their cultivation. Calceolarias of the semi-shrubby section, such as *C. Cibrani*, *Allardii* and *integrefolia*, must be propagated by means of cuttings. As the cuttings are often weak from old plants, I find it a good plan to take them from the young ones. Cuttings raised in this way usually grow more freely and make better flowering plants. *C. Burbidgei* is a fine greenhouse plant, and may be flowered in 7 in. pots for the conservatory stage, while if grown on in 10 in. pots they make fine large specimens some 4 ft. or 5 ft. high. *C. corymbosa*, listed by Messrs. Sutton as *Fairy Queen*, is a fine greenhouse plant, and should be grown from seed, giving it the same treatment as the large-flowered herbaceous section.

Azaleas of the indica section should now be stood outdoors on a bed of ashes. Large plants should be plunged sufficiently deeply to prevent them from blowing over. The plants require strict attention as regards watering, and they benefit by frequent application of weak soot water and liquid manure. Weak applications of good guano are also safe. The Azaleas should be vigorously syringed morning and evening, as they are liable to attacks of thrip.

Ericas, Acacias, Callistemons and other hard-wooded plants should be stood outdoors to ripen the flowering wood.

Sparmannia africana should also be stood outdoors, as this is the only way to get this plant to flower freely. If kept indoors the flowering wood does not get sufficiently ripened.

Salvias.—There are quite a number of Salvias that are excellent for winter flowering, especially in the country. In the immediate neighbourhood of London they are very uncertain, as one night's fog is sufficient to ruin them. They should now all be placed in their flowering pots and stood outdoors on a hard ash bottom, or they may be planted out in the reserve garden, from whence they can be lifted and potted up during the autumn. By this method they require less attention as regards watering, and they are less subject to attacks of red spider, to which *S. splendens* and its varieties are very prone. The best varieties for winter flowering are *S. splendens* and its variety *pyramidalis* for large specimens, and the variety *Glory of Zurich* for smaller plants for furnishing the benches in the conservatory. Other good species are *S. rutilans*, *S. involnerata* Bethell, *S. azurea grandiflora*, *S. rubescens* and *S. Heern*. They are all strong-rooting plants, and require abundance of water and liberal feeding when their pots are well filled with roots.

Mesembryanthemums *falciforme*, *violaceum*, *Brownii*, *aurantiacum*, *roseum*, *coccineum* and *blaudum* are all very free-flowering species, and are worthy of more general cultivation for the cool greenhouse. They are easily propagated at any time by means of cuttings. It is not necessary to put them in a case, as they root readily stood on a bench in the greenhouse. If cuttings are inserted at this time, they will make good flowering plants for next year. They grow freely in ordinary potting compost with the addition of plenty of old mortar rubble.

The "VILLA" SPRAYER

PATENT NO. 161730. BRASS CYLINDER 17 IN. LONG X 7/8 DIAM.

"The Villa" Sprayer is now fitted with a new and greatly improved nozzle. It is connected to the pump with the same sized screw as the old pattern, so that the old one may be unscrewed and replaced by that shown in the cut above. Instead of the inlet valve being operated by a rubber band a BRASS BALL VALVE has been substituted. There is nothing whatever to go wrong or to corrode. The liquid may be sucked up from the very bottom of the can. By loosening and tightening the brass screw the spraying tube may be set to throw the spray at any desired angle, and it is more solidly constructed. Former customers may be supplied with this new nozzle, post free, 1/6. Ask your seed-man or ironmonger for the "Villa" Sprayer.

THE TRADE SUPPLIED. For Wholesale terms apply: G. W. JONES, 156, Holdenhurst Road, Bournemouth.

ALPINES FROM SEED

THE raising of alpine plants from seed presents no special difficulty to the enthusiastic gardener who is prepared to cater separately for the individual requirements of the various species. The word alpine it should first be stated is intended in this connexion to cover the choicer sorts of rock plants whether they come from great elevations or comparatively low ones, and whether their native habitat be in Europe or elsewhere. Dealing first of all with home-saved seed, the amateur will wish to know how to dispose of his harvest—whether to sow it forthwith or to save it until “the turn of days.”

Seeds of *Primula* or *Androsace* should certainly be sown at the earliest possible moment, and although seeds of most species of *Saxifrage* will germinate if sown at the end of the year, a better percentage of plants and more vigorous ones are obtained if seed is sown at once. It is wise, then, to sow as many of the choicer species as possible soon after ripening, but as circumstances sometimes make it impossible to sow the whole, it may be well to mention the genera which should, in any case, be sown forthwith. Such are the *Primulas*, especially the *Candelabra* section and other soft-leaved varieties. Seeds of the *Auricula* like species, such as *P.P. hirsuta*, *villosa*, *Auricula. integrifolia*, etc., keep better, but even these are better sown immediately. The *Gentians* have seeds notoriously difficult to germinate if kept, but the seedlings usually appear early the following spring if sowing is carried out immediately the seeds are harvested. Prompt sowing is very desirable with the stone-like seeds of *Lithospermum*, *Onosma* and *Myosotis*, but it is not essential.

For choice alpine seed pans should, wherever possible, be used. It is much easier to keep the soil evenly moist in them than in boxes. Whether round or square pans are employed will depend to a large extent upon the quantity of seeds of each variety or species available or, if seed is plentiful, the number of plants it is desired to raise. The square pans, naturally, waste less space than the round ones, and

are, especially when packed together, more easily kept evenly moist, so that, where large pans are necessary, the square ones should have preference. “Old hands” often sow three or four species, which they know by experience will germinate and grow on together and which require similar compost, in the same pan, but the beginner will be wise to keep each species in a separate pan. Even the expert occasionally gets “left” through attempting several species together, for seeds are apt to behave differently under varying climatic conditions.

The compost is, for many species, of the first importance, but the following readily procured ingredients will cover all requirements: Clean,

sweet fibrous loam from the top spit of an old pasture, brick dust, broken iron furnace slags or broken potsherds, coke dust such as will pass a ½ in. sieve, old mortar rubble (pass the fine through a ½ in. sieve, but save the rough lumps), thoroughly decayed leaf-mould, fine peat, fine silver sand and live sphagnum moss.

It is not possible in the course of an article such as this to suggest a compost for each species, but a careful study of the habits of the plant it is proposed to raise will, if the following hints are carefully studied, suggest the most favourable ingredients. The alpine *Gentians* (as distinguished from the bog species), such as *G.G. verna*, *brachyphylla*, *bavarica*, *Kochii*, *Clusiana*, *angustifolia* and *Gentianella*, like a gritty soil. Having filled the pan half-full of coarsely broken potsherds or rough coke dust to ensure drainage, let us make up therefore a compost consisting of two parts fibrous loam, one part leaf-soil and four parts broken brick, potsherd or furnace slag with a little coke dust, all passed through a ½ in. sieve. For the lime-loving *Clusiana* two parts of mortar rubble should be substituted for two parts of the “ballast.” With reference to this last it will be sufficient to pass potsherd or furnace slag through a ½ in. riddle, but broken brick is apt to contain too much fine powder and should be riddled on a ½ in. sieve to remove this. The ½ in. sieve will be suitable for riddling the covering compost, which should be taken from the heap of compost already made up. Bury the seeds to a depth of twice their depth.

The compost described for *Gentians* may be considered a standard one for many stone-loving alpine plants. With the mortar rubble it is ideal for *Æthionemas*, the choicest *Campanulas*, many of the *Androsaces*, the *Encrusted* (*Euzoonia*) and most of the *Tufted* (*Kabschia*) *Saxifrages* as well as those of the *oppositifolia* (*Porphyrium*) type, many of the fleshy-leaved *Primulas*, *Potentilla nitida*, the chalk-loving members of the *Dianthus* family, the choicer *Arnicas*, *Papaver alpinum*, *Aquilegia alpina*, *A. narcissiflora*,

RAMONDIA PYRENAICA COMES FREELY FROM SEED

SEEDS OF THE BRIGHT ROSE-COLOURED DIANTHUS ALPINUS
GERMINATE QUICKLY.

THE UNCOMMON MAGENTA FLOWERED PRIMULA MEGASEFOLIA.
All Primula seeds should be sown as soon as ripe.

Gnaphalium and Leontopodium, Geum reptans and *G. montanum*. Without mortar rubble it will suit some Saxifrages which do not like lime—*S. mutata*, for example, *Dianthus glacialis*, most *Silenes* (but *S. quadrifida* likes lime), *Lychnis alpina*, *Anemone sulphurea*, *A. Pulsatilla*, *A. montana*, *A. Halleri*, *A. vernalis*, *A. baldensis*, *Douglasia* (Androsace) *Vitaliana* (a little more leaf-mould is beneficial) the *Linarias*, especially *L. alpina* and its colour forms, and *L. petraea*, *Erinus*, *Sedum* and *Sempervivum*.

A silky compost consisting largely of peat, leaf-mould and loam, but with an admixture of fine ballast and coke dust, will suit the peat-loving Androsaces *A. carnea* and *A. Loggeri* and *Myosotis rupicola* and *M. alpestris*, the *Cyclamens*, *Soldanellas*, *Cortusas*, *Pyrolas* (not always easy to raise), *Dryas*, *Coronilla*, *Oxytropis*, *Hepaticas* and *Anemone angulosa*, the *Ranunculuses*, *Trolliuses* and choicer *Aquilegias*.

Some genera there are which, delighting in a cool root-run, are best raised in a stony compost containing a proportion (say one-fifth) of chopped sphagnum moss. Probably many of the genera mentioned in the last paragraph would appreciate this treatment, which is absolutely necessary for *Eritrichium*, and might probably be desirable for *Myosotis rupicola*. The *Eritrichium* comes readily from seed in such a compost, and may be flowered in pans under glass if great care be taken, but the writer has always failed to establish it outdoors. *Soldanellas* appreciate the more even state of moisture induced by the sphagnum, and may usually be flowered the second year from seed. The beautiful and quaint *Pinguiculas* appreciate the sphagnum at all stages of their culture. The amateur who is determined thoroughly to understand alpine plants will try an equal number of seeds in alternative composts and note results. The elevation and climatic conditions of his station will make a considerable difference and he will sometimes get surprising results.

A compost consisting largely of peat and silver sand with just a little loam to give it body will suit the Heaths—*Erica*, *Calluna*, *Daboecia* and *Menziesia* and other American plants, including *Rhododendrons*. These plants, once grown, will succeed in any turfy, lime-free loam, but the seed-pans must have abundance of peat or leaf-mould, or no seeds will germinate.

A similar compost, but with the addition of a considerable amount of ballast will suit the *Ranuncias* and *Haberleas* which, though rather slow are, given ordinary care, sure enough from seed. Shade is necessary for them, of course, and water must never be permitted to lodge in the crowns.

Once the seeds are sown, covered and watered in, they should be placed in a frame with a north aspect, separating them into two classes—those which need an exceptional amount of water prior to germination and those which do not.

The finer seeds should have the pans soaked by dipping in water almost to the rim, thus allowing the moisture to percolate upwards, but most sorts may be thoroughly soaked by watering them overhead with a fine (raining) rose on a gallon-size watering can. A Haws' can with the flat rose on (holes upward) is ideal for the purpose. It is a little surprising that these excellent cans are not even more used than they are. In many gardens one still sees the old "boss" rosed can in use—a singularly primitive and unprofitable implement.

Immediately germination takes place further segregation will be necessary. The *Primulas*, *Pinguiculas* and such like will like the cool aspect of a frame facing north, but the Encrusted Saxifrages and many true alpine plants will need one quite in the open and facing west at it be summer-time or facing south in winter.

Pricking off, as a general rule, should take place as soon as the seedlings are large enough, but it is not wise to prick off the plants towards the end of the year, when growth has become slow or ceased altogether. Better in such case leave them in the seed pans until spring. The compost for pricking off should be similar to that used successfully to carry the seedlings so far, but may, naturally, be a little coarser. Rosetted plants such as Encrusted Saxifrages and "miffy" ones, such as *Eritrichium* or, perhaps, *Cyananthus*, may well have bits of stone or brick or even, if lime loving, hard mortar rubble packed round their collars, if one has patience to do this.

It will be noted that nothing has been said as to the raising of the more commonplace rock plants, such as *Aubrietia*, *Alyssum* and the commoner *Arabises*. The reason for this is sufficiently obvious. Seeds of these plants are as easy to germinate and the seedlings as easy to raise as those of bedding *Lobelia*, for instance, and considerably easier than most amateurs find *Stocks* or *Asters*. The only danger with such things is that they may be raised and kept in too high a temperature when, in addition to becoming a ready prey to insect pests, they are apt to damp off.

THE BORDER PINK

Its Development, Prospects and Cultivation.

THE Border Pink, a flower which a generation ago seemed entirely to have become a back number as far as garden decoration was concerned, to-day shares with the Rose and Iris the honour of being in the van of progress. The decline of the Pink in popularity came about through its culture as a florist's flower. Perfection of form and regularity of marking are excellent things in themselves, but when they are pursued at the expense of habit, vigour and freedom of flowering, when, in short, a humble but valuable border flower becomes fit only for the greenhouse and the show bench, its appeal to the ordinary flower-lover has gone.

Strangely enough, the "come-back" of this fragrant and beautiful flower is largely due to one of the old school of florists. Mr. Herbert, whose happy accident in raising and recognising the merit of Progress and continued careful selection since, have probably done more to re-establish the Pink in favour than the work of all other raisers together, is a real florist. It is more than probable that he is the most skilful dresser of a Carnation alive to-day. This "florist" outlook is shewn by his affection for his variety Model, which produces more perfectly shaped flowers from an exhibition standpoint than any other Pink or Carnation in existence. The Herbertii, as Pinks of Mr. Herbert's strain are often called, though they vary a great deal, all throw shapely flowers, and in addition they have the other essential qualities of constitution, hardihood, habit and freedom of flowering.

These Pinks shew evidence of Border Carnation blood. Mr. Herbert is confident that none has been introduced at his nursery either by accident or of set purpose. The Carnation characters which they possess must therefore represent a throw-back to some Carnation blood introduced experimentally, or possibly inadvertently, into one of the florist Pinks which were the parents of Progress or one of their ancestors. Few who have seen or grown them will deny that they have "Border" blood in them.

The Allwoodii, of which so many have of late years been sent out by Messrs. Allwood, admittedly have Carnation blood, but in their case it is the Perpetual Carnation which has been utilised, so that the plants flower over a much longer period than do the Herbertii. The Allwoodii have many friends and many detractors. Their friends are those who take them as very useful hardy plants which can be utilised for garden adornment in many ways—for edgings, for under-planting and what not. Their detractors point to the imperfect finish of the individual blossoms and to what they are pleased to describe as the weediness of their growth. Their very ease of

propagation is held up against them as if it were a fault!

The fact is that Herbertii and Allwoodii are both valuable garden flowers, but despite their apparent similarity of breeding they are almost as wide apart in their characteristics as the Poles. The Herbertii are free to flower—considering the size and quality of their blossoms very free to flower—and their flowering extends over a considerable season, being a great improvement in this respect on the old garden Pinks, now typified by Mrs. Sinkins. Allwoodii are marvellously floriferous, and after the first heavy crop continue to flower to a smaller but still very considerable extent the summer through.

Herbertii are ready enough to propagate either from layers or cuttings, but they will not root from cuttings in the haphazard manner sufficient for Allwoodii, nor may the plants be pulled apart

TYPICAL FLOWERS OF DIANTHUS HERBERTII.

and replanted. When it comes to winter hardiness, however, it is another story. The Herbertii are of unimpeachable hardiness—equally oblivious of wet or frost. Allwoodii, like the Gaillardia, for instance, are apt to succumb in wet winters, particularly in heavy soil. This applies more especially to older plants. Risk of winter loss may be minimised if not entirely overcome by regular propagation.

Again, a comparison of the flowers of the two strains discloses a vast difference. The original Allwoodii made little pretension to perfection of form in the individual flower. The newer introductions are admittedly much better in this respect, but still leave something to be desired. Their flowers are, on the average, much smaller and lighter than those of the Herbertii. Again, as to colour range, there is a vast difference, for whereas the Herbertii are now obtainable in most of the shades known in the Carnation, Allwoodii, though their colour range is considerable, follow at present the rather duller colourings which have always

been associated with the Pink. It will be seen, then, that these two strains each represent a great advance on anything known before, but progress has proceeded in entirely different directions. Perhaps by selection and interbreeding a strain may ultimately be evolved possessing most of the strong points of both.

The future of the Border Pink is not entirely dependent on these two hybrid races. Mr. James Douglas has a whole race of Border Pinks which are obviously all Pink. These, like the Douglas strain of Border Carnation, are mostly of splendid habit. The flowers, which have a wide range of colour in what are generally accepted as Pink shades, are of medium to large size, bright and shapely. These are not, of course, perpetual flowering, but they give a brave show in their season, and their foliage is beautiful the year round.

Another assiduous worker among hardy Pinks is Mr. Maurice Prichard of Christchurch, whose brilliant scarlet and crimson hybrids have at various times attracted considerable attention. These, however, beautiful though they are, have neither the foliage nor the habit we usually associate with the Border Pink. Just recently Mr. Prichard has exhibited hybrid Pinks, probably with *Dianthus alpinus* blood, which may be described as very much enlarged and perfected editions of *Dianthus neglectus*. The single flowers are wonderfully round and about as large as *Dianthus Herbertii* Model.

Attention has of late once again been given to hybrids between Carnation and Sweet William. Hitherto these have not proved good garden plants, and the writer is rather doubtful whether much permanent good will come from this rather fascinating cross. In any case they hardly come within the scope of this article, since they bear their flowers in flat-headed trusses somewhat similar to those of the Sweet William.

To sum up, the best results so far achieved with the Border Pink have come from the introduction of Carnation blood, either Perpetual or Border, but there is every reason to hope for still further advance through the introduction of alpine blood.

It is very interesting to observe how the characteristic zone of the Pinks persists in the Herbertii. In the deep black crimson and crimson purple forms it is difficult to trace the zone, but the fully double salmon pink ones, which at first sight seem self, shew on closer inspection a zone of darker colour, which, incidentally, as providing a darker centre to the flower, gives it richness of tone. This zone is very persistent in the Pink. Such "self-coloured" sorts as Mrs. Sinkins and Her Majesty have it, though it is represented only by a green suffusion of the petals.

Mr. Herbert's three novelties for which he received awards of merit at Chelsea Show were very attractive. The delicate colouring of Bridesmaid attracted much attention, but a flower of deeper colouring, as yet unnamed but of excellent shape and just the shade of an Eucharistess Carnation, will be even more popular when known. Red Indian is a full but very shapely flower of rather uncommon colouring. Of the older sorts of Herbertii in commerce I should select the almost black-crimson Victory, a medium-sized double flower; Queen Mary, rosy pink and deep crimson; Mrs. George Walker, old rose colour, a fine flower and "good doer"; May Queen, clear bright pink, very charming; Model, for its perfection of shape rather than for anything unusual in the colouring; Imperial, with crimson-scarlet blossoms; and Negress, a deep plum colour. All are good, however, and when some of the wonderful shades now in existence, but not in commerce, are put upon the market the colour range will be truly remarkable.

H. H.

BROOMS AND GENISTAS OF FULL SUMMER

TO the nurseryman (I think it was Mr. T. Smith of Newry) who gave us the late-flowering forms of the Common Broom (*Cytisus scoparius*) we gardeners owe much, for by growing these we can prolong the splendour of the spring-flowering native right through to August. The late-flowering Broom does not differ from the type, save in its season of blooming, but it has a stronger habit, many specimens will be curiously leafy as compared with the ordinary kind, and a certain rigidity in the long flowering branches, which, when they break horizontally from the 8ft. to 12ft. stem, to dip at the ends when weighted with their load of flowers, give the shrub a distinctive character. These late Brooms are readily raised from seed, and a few *Andreas* forms will often occur among them.

Next in importance, giving beauty of habit and ease of culture first consideration, one must place *Genista virgata*, which, though a native of Madeira, seems perfectly hardy. This is a first-rate species for a barren, porous soil, and young plants (easily produced from seed sown outdoors in mid-summer) grow away rapidly and quickly come into the flowering stage. *G. virgata* may be grown either in the mass or as a single specimen. I prefer it in the latter way, for it will make a most imposing and compact mound 10ft. to 12ft. high and as much through, the bush being clothed to the ground with its multitude of fine twiggy growths, which are well furnished with tiny leaves the silky hairs of which give the whole shrub a soft and silvery grey appearance. The terminal branchlets break into blossom usually about the beginning of July (this year they were a fortnight earlier), and when they are all bearing their slender racemes of little yellow flowers a well grown specimen of *G. virgata* is a most glorious sight.

Before the Madeiran Broom is quite over *G. retensis*, a native of Sicily, comes into blossom. This is not such a hearty-looking shrub as the foregoing, for it often assumes a rather gaunt habit, the single stem breaking at the head into a number of thin and drooping, entirely leafless branches. But at about this season, or it may be in August, these apparently lifeless twigs give forth a tender new growth, and upon these fresh and sappy branchlets, which carry a few delicate leaves, are the flowers borne. These blossoms are, individually, about the size of those of the May Broom (*Cytisus præcox*), a rich golden yellow and very fragrant. They set seed in a favourable summer, and the species is best propagated by that means. *Genista atnensis* will also grow to 10ft. or more in height, and it, again, is a rare shrub for a hot, dry soil. It seems to be as hardy as most of the Brooms in general culture. *G. monosperma*, of somewhat smilar habit of growth, but bearing clusters of white flowers upon its pendulous twigs, is also a Sicilian and a very lovely and interesting species, but so far we have failed to induce it to withstand our winters.

Cytisus nigricans is one of the most important of the July-August Brooms, and a fine thing for grouping on dry banks in association with Heaths and other sun-lovers. The habit is somewhat slender and the bushes reach a height of about 6ft., throwing out in the late summer terminal shoots which bear long and elegant racemes of yellow flowers. There are several forms of *C. nigricans*, such as *Carlén* and *longispicatus*, both with even longer flower sprays than the type, the former being distinguished for its more extended season of flowering.

C. austriacus is a useful species, inasmuch as it yields its principal display of yellow flowers

in late summer. It makes a bush some 3ft. high, and there are several forms, a curious departure from the type being *axillaris*, which bears its blooms at the leaf axils instead of at the ends of the shoots. *C. decumbens*, a trailing species, will often flower as freely in July or August as it does in spring, and another good rock garden kind is *C. Heuffeli*. Then there is *C. racemosus* (*Genista fragrans*) well known in greenhouses, a most sweetly scented and admirable shrub for a warm place. Indeed, this is much hardier than is generally supposed, and might be grown successfully even without a wall in most of our milder counties. Here it has wintered well in the open without protection, and if it is the first to come into flower it is among the last to yield to autumn.

The finest of our native *Genistas* is *G. tinctoria*, of which there are two well known forms, a double-flowered one and *G. t. var. elatior*, which hails from Eastern Europe. This last is a handsome

make little mounds or mats of gold from now onwards

Though it belongs to a different genus, *Spartium junceum* is altogether too fine to be omitted when speaking of Brooms, yet it is now so well known that one need not enter upon a description of its rush-like stems and large, clear yellow, long-stemmed flower clusters which look like golden Sweet Peas and smell like a Bean field. *S. junceum* is one of the most admirable shrubs ever introduced to English gardens, for it is not only beautiful and fragrant when in bloom, but it will flower from before midsummer to nearly Christmas, will thrive almost anywhere, is perfectly hardy, and quickly and easily raised from seed sown in the open ground. The Spanish Broom, as it is called, is practically everyone's shrub, excellent for town gardens, while the blossoms are first-rate cut for table, and the more the bushes are snipped the better do they seem to thrive. A.T.J.

C. racemosus withstands average winters in many parts of the Midlands if not exposed to morning sun, but not everyone will subscribe to

EARLY-FLOWERING SPECIES.

Name.	Colour.	Height.	Flowering Season.
<i>Cytisus albus</i>	White	10ft.	May.
<i>C. Ardoini</i>	Golden	Prostrate	April—May.
<i>C. Beani</i> (<i>Ardoini purgans</i>)	Bright yellow	1ft.	May.
<i>C. Dallimorei</i> (<i>scoparius Andreasii albus</i>)	Bright lilac-rose	8ft.	May.
<i>C. decumbens</i>	Yellow	Prostrate	May and June.
<i>C. kewensis</i> (<i>Ardoini albus</i>)	Sulphur-yellow	1ft. (prostrate)	May.
<i>C. monosperma</i>	Bright yellow	6ft.	May.
<i>C. præcox</i> (<i>purgans albus</i>)	Sulphur	8ft.	May.
<i>C. purgans</i>	Golden yellow	3ft.	April—May.
<i>C. purpureus</i>	Purplish	1½ft.	May.
<i>C. p. var. albus</i>	White	1½ft.	May.
<i>C. p. var. roseus</i>	Pinkish	1½ft.	May.
<i>C. ratibonensis</i> (several varieties)	Bright yellow	4ft.—6ft.	May.
<i>C. scoparius</i> (Common Broom)	Golden yellow	6ft.	May.
<i>C. s. var. Andreasii</i>	Crimson-bronze and yellow	6ft.	May.
<i>C. s. var. flore pleno</i>	Double yellow	6ft.	May.
<i>C. s. var. pendulus</i>	Golden	Prostrate	May.
<i>C. s. var. sulphureus</i> (Moonlight Broom)	Sulphur yellow	4ft.	May.
<i>C. sessilifolius</i>	Bright yellow	6ft.	June.
<i>C. versicolor</i>	Yellowish rose	2ft.	May.
<i>Genista glabrescens</i>	Yellow	2ft.	May.

LATE-FLOWERING SPECIES.

Name.	Colour.	Height.	Flowering Season.
<i>Cytisus Heuffeli</i>	Yellow	1ft.	July and Aug.
<i>C. hirsutus</i>	Yellow	1ft.—2ft.	July and Aug.
<i>C. leucanthus</i>	Creamy white	1ft.	July and Aug.
<i>C. nigricans</i>	Yellow	4ft.	July and Aug.
<i>C. supinus</i> (including <i>C. austriacus</i>)	Yellow	3ft.	July and Aug.
<i>Genista atnensis</i>	Golden yellow	15ft.	July.
<i>G. auzelia</i>	Yellow	8ft.	June and July.
<i>G. cimetea</i>	Yellow	8ft.	June and July.
<i>G. dahmatica</i>	Yellow	Prostrate	June and July.
<i>G. germanica</i>	Yellow	2ft.	June and July.
<i>G. hispanica</i>	Yellow	2ft.	June and July.
<i>G. radiata</i>	Deep yellow	5ft.	Late June.
<i>G. sagittalis</i>	Yellow	1ft.	Late June.
<i>G. tinctoria</i>	Yellow	2ft.	June—Sept.
<i>G. t. var. flore pleno</i>	Yellow	2ft.	June—Sept.
<i>G. t. var. elatior</i>	Yellow	4ft.	June—Sept.
<i>G. t. var. nantica</i>	Yellow	2ft.	Early June onwards.
<i>G. virgata</i>	Bright yellow	12ft.	June—July.
<i>Spartium junceum</i>	Bright yellow	10ft.	June—Sept.

shrub and the largest of the trio, growing up to 4ft. or more. When covered with its yellow blooms it is a very welcome object at the "back-end" when flowers are getting few. The native type is barely half as tall, deep green in its glossy leafage and a profuse bloomer. Not less strikingly green in the driest of dry places is the double form, and though this is much dwarfer, almost prostrate, it is a showy little plant.

G. radiata is rather a tender southerner, up to 3ft. in height, a pretty plant for the sunny side of a sheltered rock garden or dry wall, where its terminal spikes of yellow blossoms will prove effective for many weeks of late summer. *G. sagittalis*, with its winged stems and upright shoots of silky flower-heads, is familiar to most and a fine thing for covering a hot place. In addition to these the rock gardener will find in any good list some half a dozen more *Genistas* of a quite dwarf and often spiny type which will

Mr. Johnson's estimate of the hardiness of *Spartium junceum*.

The subjoined list of the more desirable species of Broom and some of the more noteworthy hybrids and varieties, with colour of blossom, approximate height and flowering season should be of value to planters.

Speaking generally, the less pruning Brooms get the better they look, but there are exceptions. If pruning must be done to reduce the size of the bush, this should, with most species, be carried out in winter. *Cytisus purpureus* should have the old wood cut out immediately after flowering. The species grouped in the late section flower on wood of the current year, and may be pruned back fairly hard before growth commences in spring. Many species make more shapely trees if cut back hard once or twice when young, but in the case of purchased pot-grown specimens this has always had attention.—Ed.]

FRAGRANCE IN THE ROSE

RECENT articles and correspondence in the daily Press have brought up the question of fragrance in flowers in general and of the Rose in particular. Scaremongers would have us believe that fragrant flowers are becoming things of the past. Readers of THE GARDEN will know that such is very far from being the case. The proportion of really scentless Roses, leaving Ramblers aside, never very great, is probably smaller to-day than it was a few years ago.

It is, naturally, difficult to raise a variety with obviously a large preponderance of Tea blood and yet possessing the perfume of the Damask. Neither can we expect raisers to discard a Rose of many excellencies just because it happens to be deficient in scent, especially as there are so many folk with excellent eyesight whose sense of smell is either entirely wanting or hopelessly rudimentary!

It must be granted, however, that perfume is eminently desirable, especially in varieties intended for cut flower. The following excellent sorts are among the most fragrant: General McArthur, Hugh Dickson, George Dickson, Château de Clos Vougeot, Jonkheer J. L. Moek, Ulrich Brunner, Général Jacqueminot, Avoca, Florence H. Veitch, Richmond, Lieutenant Chauré, Liberty, Commandant Félix Faure, Zéphirine Drouhin, Mrs. A. E. Coxhead, Mrs. John Lang, Mrs. George Norwood, Gustav Grunerwald and Laurent Carle, all the above in shades of crimson, deep rose and carmine; Conrad F. Meyer, Mme. Abel Chatenay, Pharisæer, Ophelia, Lady Alice Stanley, La France and Augustine Guinoisseau in pink shades; Mrs. Foley Hobbs and Mme Alfred Carrière, almost white; The Queen Alexandra Rose, Duchess of Wellington, Dr. Joseph Drew, Eugénie Lamesch and Marechal Niel in copper and yellow shades. Three of the Wichuraiana hybrids in addition are noticeably fragrant, namely, Léontine Gervais, François Juranville and Evangeline.

The varieties given must by no means be taken to exhaust the list of sweet-scented Roses, though most of the powerfully fragrant sorts are included.

Quite apart from these, there are, of course, the Moss Roses with their curiously sharp but pleasing fragrance and the delightful Hybrid Sweet Briars with scented foliage, not to speak of the old Damask and Provence Roses still procurable by those who wish. The Musk Rose, *Rosa moschata*, yields a characteristic and charming if not overstrong perfume not, so far, noticeably transmitted to its descendants.

The incidence of perfume among seedlings is very interesting but as yet imperfectly understood. This not only in the cases of Roses, but of other flowers which may be either scented or scentless. It certainly seems that in some cases the presence of two special colour factors will inhibit the factor for fragrance from appearing in that particular cross though it may reappear in the next generation.

TROLLIUSES

AFTER an interval of more years than I care to remember I have once more Trolliuses in the garden. Last autumn I went out into the

highways and hedges and compelled all I could find to come in, and thus the garden was furnished with guests—good, bad and indifferent. It is too soon to pronounce any sort of a final ex cathedra judgment upon their relative merits, but I may say that I am confident that some are

THE OLD FRAGRANT DAMASK ROSE.

much better than others. Perhaps another year when the plants have got into their stride once more the order of preference will not be exactly the same; meanwhile may I suggest as worthy of trial the following varieties: Newry Giant (deep orange, rather late flowering), Ophir (magnificent large orange), Mrs. Harkness (pale orange), Giantball (yellow), Lemon Queen (pale yellow), Potten's variety (an improved European), Intrusion (dwarf, small flowered, early and free) and Triumph (rich yellow, one of the latest to bloom). On looking at my garden book I find that every one of these interim selections came from Mr. G. W. Miller of Wisbech. He supplied me with excellent plants. Only one variety out of the thirty-two which came from him did not do well. To be a wee bit Irish, old Miller's the boy for Trolliuses. The surprise of my large collection up to now is Intrusion. It is a plant apart—a sort of General Tom Thumb of the Trollius family, but so well proportioned in height of stem, foliage and flower that it looks perfectly all right in every way. Another point that no one could help noticing is the great difference in the foliage between that of the new-comer *pumilus yunnanensis* and that of all the other brethren. It reminds me of Hepaticas, whereas that of the rest suggests very finely divided Buttercup leaves. I feel I really must call attention to what splendid plants all the Trolliuses are for cutting. Not only do they last well in water, but the slightly feathered stems give such a comfortable well filled appearance to a vase that no other greenery is necessary. It is rather surprising that Trolliuses are not more largely grown than at present seems to be the case.

MAJOR.

THE FRAGRANT HYBRID NOISLETTE MME. A. CARRIERE, AN ADMIRABLE CLIMBING ROSE.

MORE ABOUT THE SUMMER ROSE SHOW

MOST of the many baskets of Roses in the amateur section were very beautiful. The best basket of fourteen blooms of one variety was that of Hugh Dickson, shown by Mr. G. C. Sawday, while Mr. Wettern was a very good second with Avoca. A tasteful association of the Lyon Rose and Mrs. Foley Hobbs by Mr. G. Marriott won the first prize in the class for a basket of not more than two varieties, and Mr. Marriott was also first in the other basket classes; his basket of Los Angeles was the best of very many praiseworthy efforts. The decorative Roses in baskets were also very effective and brought many exhibitors. Mr. H. L. Wettern, Mrs. Henry Balfour and Mr. F. H. Fieldgate won the first prizes.

The special tent was well filled with dinner table and other decorations and many meritorious arrangements had to go unrewarded. In the open dinner-table class, Mrs. May, Waltham Cross, was first with a tasteful arrangement of Ophelia. Mrs. A. R. Bide, Farnham, was second with a bright table of Emma Wright, and Miss Pemberton was third with The Adjutant. In the Amateurs' Class, permitting only single Roses, the competition was very severe and here Mrs. Courtney Page was first with a charming table of Irish Elegance, while Mrs. Barton, Chappell, who used Isobel, was second, and Mrs. Oakley Fisher, showing her name variety, was third. Mrs. Courtney Page was also first in the dinner-table class which permits the use of any varieties except singles and she used Mme. Butterfly very tastefully. The Nickerson prize was won by Mrs. Barton, who combined Padre, Irish Fireflame, Smstar and Irish Elegance very effectively, while Mrs. Courtney Page was

second with a delightful table of Mable Morse and Ethel James.

The best bowls of Roses in the various amateurs' classes were arranged by Mrs. Barton, Mrs. Oakley Fisher, Mrs. E. M. Barnett and Miss Ethel James, while in the nurserymen's class Mrs. A. Bide was first with a tasteful bowl of Irish Elegance and Irish Fireflame.

In the nurserymen's classes it was a great day for Messrs. Alex. Dickson and Sons, who repeated their successes of last year by winning the champion trophy and gold medal with seventy-two splendid exhibition varieties and being also again first with thirty-two distinct varieties, three blooms of each. In the championship class they had in Mrs. G. Marriott the silver medal Hybrid Tea bloom of the open section and also beautiful examples of Archie Gray, Florence Pemberton, Snow Queen, Dean Hole, Mrs. G. Sawyer, Lady Inchquin, H. V. Machin, Marjorie Bulkeley and Mildred Grant. Their trebles were also a wonderfully good collection, and of them the very best were Mrs. G. Marriott, Molly Bligh, Dean Hole, Edward Bohane, Florence Pemberton, Mrs. Fred Searle and Lady Barham. In the championship class Messrs. Hugh Dickson, Limited, were a good second, and their very best blooms were of Gorgeous, E. Godfrey Brown, George Dickson, Alex. Emslie, Mrs. J. Laing, Mildred Grant, Mrs. G. Marriott, Pink Pearl and the Lyon Rose. Messrs. D. Prior and Son, who were third, showed good examples of such as George Dickson, Gorgeous, Florence Forrester and Snow Queen. The second prize winners in the superb trebles class were Messrs. B. R. Cant and Sons, who staged excellent sets of Gorgeous, Snow Queen, Hugh Dickson and

Lemon Pillar; while Messrs. D. Prior and Sons were third.

The China Trophy, which requires forty-eight distinct exhibition blooms, was won by Mr. George Prince, and while the exhibit did not quite reach the very high standard of the first two classes, it contained enviable blooms of Mrs. Edward Mawley, Edith Cavell, Golden Emblem, Snow Queen, Modesty and Margaret Dickson Hamill. Mr. Charles Godfrey, showing such as William Shean, the Lyon Rose and George Dickson, was second. Mr. Henry Drew, who was third, took chief honours in the class for eight varieties, three blooms of each, where he had beautiful specimens of such as Gorgeous, Golden Emblem, Margaret Dickson Hamill and Mrs. R. I. McClure. Mr. Charles Gregory, showing very fine sets of H. V. Machin and Lyon Rose, was again second, and Messrs. G. and H. Burch were third. The best twenty-four exhibition Roses were shown by Mr. John Pigg, whose outstanding sorts were Colonel Oswald Fitzgerald, White Maman Cochet, H. V. Machin, Golden Emblem and Mrs. W. J. Grant. Messrs. Chaplin Brothers were a close second.

The Tea and Noisette Roses were not equal to the high standard of the blooms in the first two classes, which nearly all were characterised by exceeding freshness, shapeliness and size and, it must be confessed, they were rather inferior to the first prize exhibits in the amateurs' section. The best nurserymen's Teas were by Mr. George Prince, who staged such as Auguste Comte, Mrs. H. Taylor, White Maman Cochet and Mrs. Campbell Hall. In the second prize collection of Mr. Henry Drew there were examples of W. R. Smith, Mrs. Foley Hobbs and Lady Plymouth.

NEW ROSE J. G. GLASSFORD, DEEP CRIMSON LAKE.

THE RICH SHIELL-PINK ROSE LADY VEREY.

New Roses always fascinate, and one turned with interest to the class for twelve blooms of varieties distributed since January 1, 1918, and while not discovering any epoch-making variety, saw quite good blooms of such as Princess Victoria, J. G. Glassford, Mrs. Lamplough and Mrs. Darlington in the first prize exhibit of Mr. George Prince.

Angeles, Château de Clos Vougeot and Mrs. Henry Morse by Mr. Mattock, while Mr. Gregory was second with Emma Wright, Christine and Golden Emblem.

The groups of Roses, as those glorious masses of cut Roses, each exhibit differently arranged but still of characteristic style, are termed, were

Henry Morse, George Dickson and Ophelia. Messrs. A. J. and C. Allen, who were second, showed beautiful stands of K. of K., Mrs. Henry Morse and Ophelia.

Although decorative effect is still aimed at, the number of varieties is restricted in the remaining classes, so these have a distinct value to the visitors who desired to select the two or three dozen or even fewer decorative Roses. The challenge cup offered for the best three dozen vases was won by Messrs. F. Cant and Co. with such as Moonlight, Braiswick Charm and Miss Ada Francis (of the cluster varieties), Donald McDonald, Ophelia, K. of K. and The Queen Alexandra Rose. Mr. Mattock, who was second, included Mrs. Redford, Rayon d'Or, Mrs. Curnock Sawday and Constance. The dwarf Polyantha Roses were also particularly well shown, and there were delightful vases of Mrs. W. H. Cutbush, Etoile de Mai, Léonie Lamesch, Perle d'Or and Baby Tausendschon in the first prize collection of Messrs. W. and J. Brown; while Mr. John Mattock had a beautiful vase of Rödhätte in his good second prize exhibit.

A BASKET OF MARGARET DICKSON HAMILL SHEWN BY MESSRS. ALEX. DICKSON AND SONS.

Messrs. Hugh Dickson, Limited, were second, and had Alex. Emsley, Mrs. J. R. Allen, Margaret M. Wylie and Marjorie Bulkeley.

The silvery pink Marjorie Bulkeley shown by Messrs. Hugh Dickson, Limited, were adjudged the best twelve blooms of any Rose distributed since January 1, 1918. Brilliant blooms of The Queen Alexandra Rose by Mr. Elisha J. Hicks and Messrs. D. Prior and Son, was the best Hybrid Perpetual. Edith Cavell by Mr. G. Prince and George Dickson by Messrs. W. and J. Brown won the first two prizes in the order named as the best baskets of Hybrid Tea Roses; while of the Teas Mme. Jules Gravereaux by Messrs. D. Prior and Son was first, and Mrs. Foley Hobbs by Messrs. W. and J. Brown was second. The seven baskets of decorative Roses that won first prize for Messrs. Chaplin Brothers were uniformly excellent, and included such sorts as Mrs. Henry Bowles, Isobel, Colonel Oswald Fitzgerald, Golden Emblem and K. of K. Messrs. Alex. Dickson and Sons were second with charming baskets of Lady Inchquin, Sunstar, Betty Uprichard, K. of K. and Margaret Dickson Hamill. The best three baskets were excellent arrangements of Lus

eagerly scanned by enthusiasts throughout the whole of the afternoon, for in them they could see the more recent varieties together with old favourites, and so properly appraise their value; while perhaps most important of all, the newest recruit to the great army of amateur rosarians could not fail to be so fascinated as to order more Roses than he or she intended when setting out for the Show. This would be a good fault, because one cannot very well grow too many Roses, and the time and skill expended in arranging these generous displays of beautiful blooms certainly deserved more tangible reward than the honour of winning the first prizes in the various classes or of being honourably beaten in the struggle. The champion group was by Mr. Elisha J. Hicks, who has secured the coveted trophy for the third successive year. His cross arches of Joanna Bridge and Mrs. F. W. Flight, of Red Letter Day and Blush Rambler, for instance, were singularly effective associations, while of the many large stands we would select those of American Pillar, Hoosier Beauty, Golden Ophelia, Ethel James, Richmond, Ophelia, Mrs. Henry Morse and Lady Hillingdon for their great decorative value. The same high quality and tasteful association were present in the second prize arrangement of Messrs. B. R. Cant and Sons, and in this were to be seen generous stands of such as Lady Pirrie, Christine and Paul's Scarlet Climber at the back, while in front were Emily Gray, K. of K., Flame of Fire and very many others.

High quality and skilful arrangement were continued in the smaller though still large groups. Messrs. Chaplin Brothers had veritable masses of bloom with such sorts as Golden Emblem, Paul's Scarlet Climber, American Pillar, Mrs.

BRANCHING IN TULIPS

BRANCHING has been very much in the limelight this last season. The abnormal summer of 1921 seems to have upset a great many Tulips, and it has been quite a common occurrence to find on a plant in place of the usual orthodox single flower as many as three, four and five. Letters have reached me asking if I can account for this strange behaviour, and enquiring if this newly acquired habit is likely to be permanent. My answer to the last question is in the negative. Experience tells me that although "branching" is in the blood of the Tulip family, as, for example, in some species like *praestans* and *dasystemon*, it is unusual in the great majority of garden varieties. The first question is not so easily answered. Unfortunately, I cannot remember if the hot summer of 1911 had a similar effect upon Tulips that that of 1921 had. Artificial warmth when the bulbs are out of the ground is nowadays not infrequently applied to retard their blooming the following year, but I have never heard that it caused the phenomenon of "branching." This seems to suggest that it was not the heat alone that caused it in 1921, but that the sun was an all-important factor. Again if, as I am inclined to think possible, there has been a branching strain of garden varieties ever since the primeval days when hybrid Tulips first reached Western Europe—that is, roughly speaking, somewhere about 1550 to 1560—it is anything but a novelty to meet with them now. On page 143 of the "Rariorum Plantarum Historia" of Carolus Clusius, published as early as 1601, there is a good representation of a branching Tulip which, if it is that of a hybrid, supports my supposition. If this be so, what we then want to know is if its branching depended on cultivation, as it undoubtedly does in the case of Monsieur S. Mottet. Starve it and there is little or no branching. Feed it on good fare and the branching is very marked. Thus branching may be the result of the stimulation of either a dormant natural propensity or a latent partly acquired habit brought about by a most abnormal season. The branching of species is naturally a subject of great interest. All that need be said now is that as far as my experience goes they follow the rule of the hybrids and that the largest bulbs produce plants that branch the most.

Coming, then, to the branching of garden hybrids, there seems little doubt that it has been known to Tulip-growers in Western Europe from

a date within fifty years after the coming of the Tulip from the East, if the picture in Clusius is that of a hybrid. From 1601 onwards pictures of them appear in "flower" books from time to time. An example of peculiar interest is to be found in the "Livre Nouveau De Fleurs," published at Paris by Baltazar Moncornet in 1645. The pictures of flowers were intended for models for workers in gold, so it is only in a secondary sense a "flower" book. Here, however, we find two distinct examples of branching Tulips, one with egg-shaped, round-topped blooms and the other totally different, as the perianth segments are decidedly pointed. The egg-shaped one seems to have been inspired by the picture in Clusius, but whence came the other? I have no idea. It may have been drawn from "life," but there is no evidence one way or the other. Judging from the other flowers in the book, Moncornet certainly did not go in for depicting monstrosities or very out-of-the-way flowers, hence the presumption is that branching Tulips were fairly well known in his day. We pass on to 1771, when we find in "The New Gardeners' Dictionary" of John Dicks another picture of a branching Tulip and in the letterpress a full description of its appearance. Somehow the illustration suggests the "Historia" of Clusius as its inspiration, and as the author's description of the plant in the letterpress is not altogether convincing as to whether it is taken from some book or from his personal observation, one rather wonders if there really were such Tulips in gardens in the last half of the eighteenth century. The name in Dicks' book—Cluster Tulip—seems to be a very happy one, and I wish it could be brought into common use to describe the race of hybrid "branching" Tulips. We again pass over a century and come to a coloured illustration of a double-flowered branching Tulip in the *Revue Horticole* for February 1, 1882. This is inscribed "Tulipe pluriflore double Roi des bleus." We see there portrayed a plant with a fasciated stem which divides into five separate ones, and at the end of each a flower much after the style of the popular Blue Flag, but of a deeper and redder shade of purple. In the letterpress a short account is given of the work of M. Marel Foulin and of M. Thiébaud-Legendre, and the writer asks, is it worth while trying to rear races of Tulips which will permanently take on this branching habit. "Ya-t-il avantage à multiplier les Tulipes pluriflores? Nous le croyons." Partly from a scientific and partly from a practical garden point of view it is, he thinks. From 1882 we pass to 1922. In the month of May in the present year a flower-basket full of magnificent stems of a deep purple Cluster Tulip arrived at my house from M. Bony of Clermont-Ferrand. Although they had been just a week on the way, they were, thanks to careful packing, still fresh enough to give one a good idea of what they were like. M. Bony's plants are tall, strong growers, and again to quote from the *Revue Horticole*, "une seule tige coupée à un certain état de floraison constitue un bouquet tout fait." M. Bony once by great good fortune found a Tulip in an old French garden which regularly threw up a branching stem. From this he has been able to breed various varieties which, like it, permanently shew the same habit under congenial conditions of culture. The one that is most widely known is that named Monsieur S. Mottet, which I must have had in my garden for at least ten or eleven years and which I find never fails to branch if the bulbs are large enough and if the ground in which it is planted is sufficiently good. Thanks to the kindness of M. Bony, I had in my garden, just before the war began, a second branching variety, but I am sorry to say something went wrong with it and it died out, so I

am unable to speak of it as a growing plant. It had, I think, a red and yellow flower. One year I sent M. Bony some of our best Cottage and Darwin varieties for the purpose of hybridisation. Then the war came and for a long time I heard nothing from him or about him. The basket, followed by a long letter, that arrived in May, was a most welcome and pleasant surprise. It told me that my friend is "alive and kicking," and the good work is still going on at Clermont-Ferrand. The wise man never prophesies until after the event, so I will only say that if M. Bony can manage to give us various self-coloured varieties with the habit and general look of

Monsieur S. Mottet (egg-shaped, white, which flushes), he will have conferred a lasting benefit on those of his fellows who, like himself and myself, are lovers of the Tulip. It is but fair to say that in normal years it is only the big, well nourished bulbs that produce the fasciated stems of the Cluster Tulip. After 1921, it is true, quite small bulbs sent up the same fasciated stems, but happily for most other plants such years do not come very often, and even for these Tulips it is unnecessary that they should do, seeing that good cultivation and big fat bulbs produce similar results in a pleasanter way in normal seasons. JOSEPH JACOB.

THE MULLEIN MOTH

An Enemy of the Mullein and Buddleia

DURING the months of June and July the larvæ of the Mullein moth, *Cucullia Verbasci*, are likely to attract attention, when various species of *Verbascum* and *Scrophularia* are liable to be almost defoliated by the pest. The leaves of *Buddleias* also sometimes shew evidences of its presence.

The moth, which has a wing expanse of from 1½ ins. to 2 ins., is on the wing in April and May, when it oviposits commonly on *Verbascum Thapsus*. It is one of the group of moths known as "Sharks." The forewings are "pale wainscot-brown shaded with reddish brown, and with a rich mahogany or dark chocolate stripe along the costal and dorsal margins. Hind wings white shaded with reddish brown, hind margin strongly crenulated." (Barrett, "British Lepidoptera.")

The moth is a strong flyer, and probably feeds on night-flowering plants and trees, since it is rarely, if ever, seen on the wing by day. It has, however, been found resting on dead twigs and bark where it is only difficultly noticeable, so completely do its form and colour harmonise with the surroundings. It is found in the South-East of England, but is more common in the West, both in Wales and its borders and in Devon and Cornwall, where, on the sparsely wooded uplands, the Mullein thrives.

THE CATERPILLAR.

The larva is a very handsome and striking one. It is described by Barrett as "Stout, rounded,

THE MULLEIN MOTH (NATURAL SIZE).

smooth, and with a few short, scattered hairs. . . . head small, yellow, spotted with black; body greenish white with a broad deep yellow transverse band on each segment from spiracle to spiracle; on each segment are also four large black dorsal spots, the second pair larger and elongated laterally; sub-dorsal line represented by two black spots and two black transverse lines on each segment, spiracles black. . . . legs and prolegs yellowish, the latter marked in front and the former behind with black."

The larvæ feed quite openly in bright sunshine, and in favourable weather grow very rapidly. The writer has seen a plant of *Verbascum* 6 ft. high completely defoliated by nearly mature larvæ in about two days. The plants most frequently attacked are *Verbascum Thapsus*, *V. pulverulentum*, various wild and cultivated *Scrophularias* and certain species of *Buddleia*. The larvæ may be found in June and July, the

LARVA (SOMEWHAT REDUCED).

duration of this stage varying according to the weather, development being retarded when it is cold and dull. When fully fed the larvæ measure from 1½ ins. to 2 ins. in length.

THE PUPAL STAGE.

When mature the larvæ burrow down into the soil to a considerable depth, where, with layers of earth and silk, large-sized cocoons are constructed. The larvæ then become quiescent, gradually contract and finally pupate. The pupa is from reddish brown to dark brown in colour. The duration of the pupal stage is very variable, some adults emerging the following spring, but others not coming forth for two, three or four years, hence the depth at which the pupæ are buried will afford considerable protection.

OCCURRENCE OF THE PEST.

Owing to a variety of natural causes which keep pests in check a periodicity in epidemics is noticeable, and if any particular pest is carefully observed over a number of years it will be seen that it recurs again and again at more or less regular intervals. This probably occurs in the case of Mullein moth. Thus in 1916 and 1917 there was a severe outbreak in the Forest of Dean, when practically every Mullein plant was seen to be attacked. Since that time little attention had been attracted to the pest until 1921, when it shewed a sudden increase in numbers, and now in 1922 reports of attack are received from Devon and Cornwall, the Bristol area of Somerset and parts of the Forest of Dean.

Mulleins, both singly and in groups in herbaceous borders, are liable to attack, and unless the closest attention is paid to the plants, the development of the attack may not be noticed until it is almost too late.

PREVENTIVE AND CONTROL MEASURES.

Very little is known about the natural enemies of the Mullein moth, though it is undoubtedly checked by various insect parasites. The larvæ feeding in bright sunshine would appear liable to be attacked by birds, and some authorities hold that birds are an important factor in destroying them. Barrett states that they are distasteful to jackdaws, and it is quite possible that they may be so to other insect-feeding birds. The larvæ are protected to some extent by their nervous excitability, for they throw themselves off their host plant and curl up in the denser vegetation below at the least touch or jar.

Where Mulleins are grown for commercial purposes this pest is of special importance, but the destruction of ornamental groups in border or wild garden is sufficiently annoying.

Where only one or two plants are attacked hand-picking the larvæ will probably be the most satisfactory treatment, but where an extensive attack is in progress spraying with arsenate of lead is the most efficacious remedy. The poison should be obtained in the paste form and used at the rate of 4lb. of lead arsenate to 100 gallons of soft water. If needful, a little soft soap may be added to give additional wetting power to the spray. HERBERT W. MILES, N.D.A.

the plant at Kew have only met with partial success. It may therefore interest readers of THE GARDEN to know that on June 24 I saw a plant of this beautiful shrub in perfect health and laden with its heath-like flowers on a south wall in the gardens of Admiral Milne, Inveresk Gate, Musselburgh.—CHARLES COMFORT.

NOTES ON THE SUMMER ROSE SHOW.

SOMETIMES the views of an "outsider" are welcome as coming from a standpoint that has at least no personal bias. The Rose Show at the Botanic Gardens in Regent's Park had so many admirers that I think they cannot all be experts in the matter of Rose growing, and really the show was so fine and the Roses so superbly well grown and well fed that I think a note of warning as well as admiration may be not unwelcome! When gazing at these fat and well fed blooms, with petals often carefully curled back and sheltered no doubt from rain and wind, how few admirers realise that such perfection is not to be attained by the ordinary grower, who

CORRESPONDENCE

SILVER-LEAF DISEASE.

I WAS much interested in the note by Mr. W. F. M. Copeland on this subject in THE GARDEN, issue July 1, page 310, as the letter referred to by Mr. Copeland was mine. Further, I am very pleased to learn that someone else troubled with the pest has benefited. I know of another case also where true silver-leaf has been got rid of by using soot as I recommended. My case, as stated last year, was, alas! true silver-leaf and testified to by such experts as Messrs. Rivers and Messrs. Dicksons of Chester. I felt sure myself, but thought it well to have the opinion of more expert cultivators. I had it. My tree, treated as I stated, was cured, and again this year it has made wonderful growth and is bearing a big crop of fine fruits. Throughout the winter soot was applied. Mixing soot with water in a bucket "a nasty job?" Not a bit of it if the work be done the right way. First mix a small quantity of soot and water and add more of both till the bucket is full and the mixture of the consistency of mortar. But it does not matter as long as the soot is washed down to the roots freely how it is applied. The soot induces a wonderfully free growth, too, and the foliage is not readily attacked by red spider.

With regard to canker in Apple trees, I may say that I have cured them when in a bad condition from it. In fact, one, a Cox's, had a hole right through the stem at the junction of branches and stem when I had finished cutting away the cankered parts. The wounds were then dressed several times with pure Fir tree oil and the roots also pruned. The following year the tree bore about half a bushel of Apples and the bark eventually entirely filled up all hollows made by the severe cutting. Very old cankered trees I should not trouble to treat, but should plant young trees instead.—GEORGE GARNER.

COLOUR IN THE GARDEN.

HOW often it happens in the garden that a colour plan is more or less of a disappointment and an accidental arrangement a brilliant success! This dry summer has seen the failure of many winter-planned combinations, but one great success that has given me much pleasure is a grouping of red Mountain Spinach (Orach) with orange Cheiranthus Allionii, self sown. Messrs. Thompson and Morgan of Ipswich sell the Orach seed. Sown in patches between other tall plants it needs no support and looks like some large kind of Prunus Pissardi.—ETHEL CASE, Swanage.

RABBIT PROOF PLANTS FOR WILD GARDEN.

MY experience, such as it is, may be of use to some of your readers who are contemplating starting a wild garden. The following

are plants which rabbits do not seem to touch: Arundo Donax, Astilbes, Aralia edulis, A. spinosa, Beschorneria yuccoides, Eremuri, Gunnera manicata, Kniphofia, Mulgedium, Phoradendron

A NUMBER OF THE RARE SUCCULENT BESCHORNERIA YUCCOIDES IN FLOWER; EREMURI IN THE BACKGROUND.

variety, Polygonum cuspidatum, P. sachalinense, Rheums in variety, Rodgersia in variety, Saxifraga peltata, Senecios in variety, Yuccas in variety. On the other hand, they will destroy Crambe orientalis, Fatsia japonica (Aralia Sieboldi) when young, Dracenas if they can reach the heart-leaves, Petasites giganteus and the young shoots of Bamboos. I enclose a photograph of Beschorneria yuccoides in flower, though I fear it is not clear enough for reproduction.—R. HATCE, Osmington, Weymouth.

[The Agave-like Beschornerias are hardy only on the seacoast, and it is not too generally known that they are hardy there. Johnson's Gardeners' Dictionary, even in the latest edition, describes them as warm greenhouse succulents. Perhaps by continued acclimatisation they may ultimately come to be hardy inland. All the species hail from Mexico.—ED.]

A RARE SHRUB.

IN THE GARDEN for July 1, page 320, "Somersetshire" writes about a plant of Fabiana imbricata growing on a south wall in a stable-yard in Somersetshire. In the Editorial note appended it is stated that attempts to acclimatise

has room in his heart but not room enough in his garden.

Yet none the less we may in our smaller degree strive after perfection, and it we have not achieved it in past days with the old Roses may we not hope to do so with the new ones? So let us gaily admire these new arrivals and note that in some cases the growers have dug up a strong young plant to shew its strength of growth or vigorous constitution—a welcome step in advance of old days. I fear, however, that the stumpy growths of such lovely Roses as Mrs. H. Moore or Florence Forrester are not *en evidence*, and the fine stand of that perverse Rose Bessie Brown, every flower of which must be tied up with wire lest it hang like a Snowdrop, is not the only instance of a Rose which is not for the ordinary Rose-lover!

The Rose reporters will tell of the awards made. I merely mention the Roses that took my fancy. There may be others still better, but the following seemed to be of outstanding interest. Of all the new red Roses shown, Captain Kilbee Stuart seems to me to be the best all round. Bright and fresh in colour, good in shape, sweet scented and of good growth. It seemed to

me as good as that fine American Rose Hadley, which is several shades deeper in colour but of the same style and excellence (I suppose it is not yet ready, as I saw no blooms shown that day). Were other folk as much disappointed as I was with the red Rose named Prince of Wales? I always feel as if a Rose should not be named after a special celebrity or favourite without due authority and consideration. I am reminded of a French friend's warning, "Never buy a Rose named after a celebrity, but when a Rose is named after another Rose grower or his daughter you may be sure it is good," and the advice holds good, I think, still.

However, Lady Roundway, Mrs. H. Bowles and Emma Wright are three such glorious Roses of orange or bright pink that I think we must all hope to have them in our gardens some day. I hear that fine but rather uncertain Rose Gorgeous is one of their parents. I must say the daughters are still more lovely than the mother. Ruth and Miriam are also to be commended. The only pity is one cannot yet say which is the best. I was interested to see the creamy white climbing Tea Rose Muriel Wilson shown so much "fatter" and more solid in petal that when I saw it on the Riviera that I felt more than ever convinced one cannot judge a Rose at one sitting. Kallisto also, which last autumn was so glorious in colour, was this day quite dull and commonplace. The table decorations alone were below the usual standard, but the setting of the Show in the Botanic Gardens was much enhanced by the greatly improved conditions of the gardens and the flowers growing there. Much praise is due to those who have achieved it.—E. H. W.

A SUGGESTION FOR EXHIBITORS.

I WAS pleased to see the charming illustration of a tropical pool as "a suggestion for exhibitors," by Mr. Brown, which appeared in THE GARDEN of June 10. I have myself suggested the construction of such a tropical pool for Chelsea. One of my earliest recollections is just such a rocky pool in a house where my grandfather grew exotic Ferns, for which he was awarded the R.H.S. silver medal in 1846. In the foreground at the sides of the pool there were some graceful Palms and a particularly fine specimen of a Date Palm which almost reached the roof. In the middle distance, growing in niches of old red sandstone rocks which rose to the height of about 6ft. were various large Ferns, Lycopodiums and *Monstera deliciosa*. The back wall of the house was completely covered with smaller Ferns, chiefly self-sown Maidenhairs. To the left of this wall a low water-tall twisted, splashing among the rocks, giving a pleasing movement to the water in the pool, from which rose the leaves of giant Caladiums. The most striking feature of the little picture was given by the plants which grew overhead. The rich mauve clusters of *Todea* mingled with the blossoms of a large tropical Passion Flower. Crimson *Taonia* flowers swung at various heights on their long threadlike stalks, like lanterns, almost to the surface of the pool, and among them their fruits, ranging from green and citron to all tones of yellow and orange. The glass of the roof for about 10ft. from the back of the house was darkened, giving great distance to the picture, but when I knew it this artificial shading was rendered unnecessary by the growth of a large India-rubber plant. Should such a scene ever appear at Chelsea, as I hope, I should like to add the beautiful blue-flowered *Nymphaea*, the Indian Lotus (exquisite both for leaf and flower) and introduce a large Banana or two in place of one or more of the Palms.—H. H. WARNER.

AN INTERESTING PARASITE.

ANOPLANTHUS COCCINEUS is a remarkable parasite belonging to the Broomrape family which grows on the roots of various plants but chiefly on those of *Centaurea dealbata*, in which case the beautiful silvery foliage of the host plant acts as a delightful foil for the large velvety flowers, which are of a brilliant scarlet colour. They are about 2½ ins. in diameter, and are borne singly on reddish brown stems 12 ins. or more high. These stems are naked, with the exception of two or three bracts on the lower halves. The flowers, which resemble those of a giant *Lobelia*, are five-lobed, with two upper and three lower lobes, the latter forming a lip at the base of which is a large black blotch. The seeds from which the plants here illustrated were grown were originally received from Tiffis Botanic Garden. They were sown, at Kew with those of the host plant, in a pot. Only the *Centaurea* appeared the first year, and this was planted out in the bed. Nothing else appeared for two years, when in May several stems of the *Anoplantus* were noticed, each

AN INTERESTING PARASITE, *ANOPLANTHUS COCCINEUS*.

with a solitary flower bud. These developed, and the flowers opened towards the end of the month. Owing to the dry weather this year the flowers did not last long, but it is a most attractive plant when in good condition with its intense scarlet blooms. After the first year two or more flowers appear annually, so that it may be called a perennial.—W. L.

THE ROTATION OF CROPS.

MR. LODGE (page 204) has opened up an interesting subject. It has appeared to me that the theory of rotation of crops has been copied automatically from one vegetable book into another, and that it requires criticism and revision. I have been surprised to see it treated as an easy thing to do, and taken so for granted. It is easy to write the names of a lot of vegetables in little squares, but to work it out in detail on the ground is another matter. The suggestions in my article in the issue for April 29 as regards a few crops are based on my own practice, and I hoped might provoke some remarks on cropping.

Some crops that require special preparation, such as Onions and Peas, are already often grown year after year on the same ground, but I cannot see any wisdom in disregarding any system of

rotation. No two crops exhaust the food constituents of the soil in quite the same manner, and in spite of Mr. Lodge's conviction, there must be increased danger of infection from any pest that has done much damage the previous year, such as Onion mildew, Pea weevil or Cabbage aphid. The case of "club" is notorious. But I have long wanted to know whether a two years' interval between crops of the Brassica tribe is necessary in a garden free from "club" but in a locality where "club" is prevalent, provided great care is exercised over the seed-bed. The chief difficulty of a three-year rotation lies in the all-pervasive Cabbage tribe unless a good deal of the ground carries only one crop in the season.

I cannot see that for roots to succeed Brassica infers poor cultivation. You may dig three spits deep if you will, and leave all three in the same relative position with regard to each other. Now, if you grow Long Surrey after Broccoli, the roots certainly go down into a level below that occupied by the previous crop. But on the way down and during that hazardous period of youth the

Carrot goes through soil exhausted by the Broccoli (the spit) having been more or less reversed in digging, and if an intermediate Carrot or Beet is grown, it does not penetrate to the second spit at all. "The rising of moisture in the soil" occurs only in dry weather. In wet weather the reverse is the case, and the nourishment of the plant would then come from above and from its immediate surroundings.

The advantage of the "over-glorified" Dutch hoe depends partly on its make. The blade is best nearly in a straight line with the handle. Like other tools, it depends also on the user. I have observed that it is not everybody's tool—the draw-hoe man often does not understand it.—G. PRICE-DAVIES.

THE AFTER EFFECTS OF THE DROUGHT

I WAS pleased to see the reference to "the after-effects of the drought" in THE GARDEN of June 24. Never have I seen such sprays of Forsythia and of the Pink Double Plum (*Prunus triloba*) and such a wealth of blossom on the Lilac, Mock Orange and Weigela. I have also had the baby Tulips in flower, to which other correspondents have referred. Mention should also be made of the profusion of flowers on the Rock Roses in, I think, every variety. Last week I visited the ancient Fig garden at West Tarring, where the remains of the tree planted by Thomas à Becket in 1102 are still carefully preserved. There are about a hundred Fig trees in this garden, and they are carrying a heavier crop of fruit than any previously recorded. The varieties chiefly grown are the Brown Turkey Fig and the large pink-fleshed Madagascar. On reaching Ventnor, where Figs are largely grown, nearly every tree was bearing a record crop. There is no doubt about this tree being a lover of heat, but it also seems able to withstand a long period of drought,

which is just what one would expect, considering its original habitats. The fine show of fruit is worth recording, and some is now ripe and being offered for sale in the town of Worthing.—H. W., *Worthing*.

LYSICHTUM CAMTSCHATCENSE.

I WAS interested in two references in your issue of May 27 to this plant by Lady Moore and Mr. A. T. Johnson. I recently received some plants of what is commonly known in British Columbia as Skunk Cabbage from a cousin living at Milne's Landing, near Victoria, who wrote me that it is there a very common plant in marshes and uncleared ditches. He further tells me that bear use it as a spring medicine as soon as they come out of their winter sleep, perhaps in the same way that dogs eat a species of grass, which I believe is Couch Grass, mentioned by Culpeper in his Herbal as Dog Grass and having certain medicinal qualities. This may be the origin of its local name. Can anybody tell me what are the medicinal qualities in *Lysichitum*? If bear use it, there is a possibility it may have some value for human beings. I wonder if someone who grows this Arum would give it a trial. My own plants are not sufficiently advanced to do so. The leaves, however, look very succulent and tempting. On the other hand, there grows in Perthshire a wild plant with a similar leaf, also known there as Skunk Cabbage. Perhaps some Scotch or Highland settler gave it this name for its similarity in leaf to the British plant. The young unfolded leaves are very similar in appearance to a spring Cabbage. How in Scotland comes the word Skunk unless it might be the ancient name for bear? My plants arrived in perfect condition packed in damp moss after a three weeks' journey, and they began to grow away at once, but the leaves were badly cut during the recent frosts. I should think that it may not be absolutely hardy in the South of England, and evidently requires a moist position where the morning sun does not reach the young spring growth. There are plants at Kew.—EDWARD SHOOSMITH.

[The Skunk Cabbage or Skunkweed of North America is *Symplocarpus foetidus*. All parts of the plant have a disagreeable foetid odour thought to resemble that of the animal after which it is named. The root is the part usually employed in medicine. It has an acrid taste and is regarded as stimulant, antispasmodic, narcotic and expectorant. The drug may be obtained from herbalists in this country. We cannot trace the name Skunk Cabbage as applied to *Lysichitum camtschatcense* or to any British plant.—ED.]

MICE AND VOLES IN THE GARDEN.

AT the beginning of the year you published a letter which I wrote advocating the use of the Colin Pullinger Balance Mouse Trap for catching long-tailed field mice and bank and field voles in the garden, so I am writing to let you know that a few weeks ago I purchased half a dozen of these traps, and on unpacking the parcel my attention was arrested by the angle of the balance, which was much more acute than I was accustomed to see it. On examining a trap more closely I found that instead of it being pivoted about one-eighth of an inch from the ground level, it was pivoted half an inch from it, thus accounting for the acuteness of the angle. I at once communicated with the makers, Messrs. Duke, Waring, Crisp and Co., 139, Wardour Street, London, W.1, and pointed out to them that at the angle of the balance in the trap sent to me, a mouse on the balance when feeling it begin to move would have time to retreat to the entrance before the

balance had passed the centre of gravity, whereas in the original Colin Pullinger trap the angle being much less acute, the weight of the mouse had carried the balance beyond the centre of gravity before the mouse had time to get back to the entrance. The firm are extremely sorry for the mistake which their workman has made, but they have no knowledge as to when he began to depart from the original model, and therefore cannot tell how many traps have been sold since the alteration in the pattern was inadvertently made. They are most anxious to do all in their power to rectify the mistake and are re-pivoting traps returned to them which

have been thus improperly put together. I am writing to mention what has occurred, for the traps as sent to me were practically useless, and unless the mistake is rectified a most efficient trap will fall into disrepute. The head of the firm came to see me about the matter and told me that they were examining their stock to rectify the mistake. He mentioned incidentally that one evening some altered traps were left on the bench and in the morning it was found that, although unbaited, two of them had each captured a mouse in the night, the mice probably being attracted to the bench by the crumbs from the workman's tea.—T. MARK HOFFEL.

GARDENING OF THE WEEK

FOR SOUTHERN GARDENS.

The Kitchen Garden.

Carrots.—It is an excellent practice to make a sowing about this time to provide some delicate young roots for autumn and winter use. They may safely be left in the ground, for should the weather be very severe a little dry straw or bracken may be strewn over the bed. For this sowing it is best to select a quick-growing early Short Horn variety, and the necessary thinning of the seedlings should be done in good time. Some growers scatter the seed broadcast for winter, and on a clean soil the plan is to be recommended, because plants strewn over the whole surface of the bed undoubtedly do lend a little protection to one another during severe weather, but on weedy soils the seed should always be sown in drills.

Celery.—Plants from the first sowing will need a little soil drawn up or the adjusting of the paper bands if blanching is carried out with the aid of these. Before doing such work all sucker growths should be removed and the plants be thoroughly watered the day previously if at all dry. There is nothing to gain in being in too great a hurry with the blanching unless the plants are required by an early date. The chief point is to keep the plants growing clean and healthy, and upon no consideration must the maggot be allowed a footing. Regular light dustings of old soot applied during the evening after the plants have been sprayed is one of the best antidotes to this pest. Any delay experienced in getting later batches into their places should be made good as soon as convenient, keeping the plants in the meantime well cared for.

Outdoor Tomatoes.—The warm weather gave these a good start and considerable growth has been made. Restrict all side growths and thus confine the plant's energies to one stem. Feeding the plants is not to be recommended until several trusses of fruits are secured and swelling, or too much leafage will be encouraged.

Cucumbers.—Some seed should be sown at once to provide plants for autumn fruiting and some again in about another month's time to supply plants for winter bearing. Keep the plants in full cropping well supplied with moisture both at the roots and atmospherically, and cut all fruits as soon as large enough to use so as not unduly to weaken the plants by carrying them too long. The fruits will keep in good condition for a week in a cool cellar in a little water.

The Flower Garden.

Carnations of the Border section may be layered at any time from mid-July until the middle of August. A light, gritty compost is the best medium for the layers to take root in, and it is a good plan previously to placing this in position to loosen the surface soil a little round the old plants. Make a clean cut on the underside of each selected shoot and press the tongue formed into the soil and make it secure with a peg. Give water from time to time through a fine rose, according to the weather conditions.

Pinks.—Cuttings or pipings of all varieties of Pinks will root readily if inserted in a sandy soil in a cold frame, which should be kept shaded until root action has commenced. Keep the frame fairly close at the commencement, but give abundance of air when roots are formed, finally removing the lights and so make sturdy stock for autumn planting. The plants now popularly known as *Allwoodii* may also be readily increased in this manner.

The Hardy Fruit Garden.

Budding Fruit Trees.—Whether it is desirable or profitable to carry out this operation in private gardens everyone must judge for themselves. Personally, unless it is dealing with some special variety, I do not think it is when plenty of firms, which regularly advertise in the pages of *THE GARDEN*, offer trees to suit any position at prices which it is fair to state must be considered reasonable. July and August are the best months for the work, when bark and sap are in a responsive condition. Of the several different methods of budding, that which is spoken of as the T method is to be recommended. When carrying out the work it is essential to have everything ready so that as soon as ever the bud is made and fitted into the T cut a little damp moss and broad raffia strands are at hand to finish the job. Choose buds from the half-ripened shoots of the present season's growth. Wood buds are distinguishable by being more pointed and thinner than fruit buds.

Fruit Under Glass.

Melons.—Seed must be sown at once where a late crop of fruit is required. This batch of plants must be grown where plenty of pipe heat will be available when required at a later date. Make the bed thoroughly firm and place a couple of seeds at intervals of 20 ins. apart on the bed, removing the weaker seedling as soon as such may be determined. Make the utmost use of all bright weather to bring the plants quickly along into a bearing condition, and as soon as two or three fruits are secured on each plant concentrate the plant's energies upon the speedy development of them to a useful size.

H. TURNER

(Gardener to the Duke of Northumberland).
Albury Park Gardens, Guildford

FOR NORTHERN GARDENS.

The Kitchen Garden.

Spring Cabbage.—Make a first sowing of early Cabbage on one of the borders that has been cleared of early crops. The seed-bed should only be moderately rich. Do not sow thickly, taking every precaution to see that the plants are not allowed to become drawn or weakly in the bed. Suitable varieties for autumn planting are Sutton's Flower of Spring, Harbinger and Eilan's Early.

Herbs.—Seedlings of various herbs raised this summer should now be planted out in nursery lines from which permanent beds may be made next spring. Water the seedlings thoroughly if the weather is dry and shade with a few Spruce branches until growth commences.

French Beans.—Encourage this important crop by placing light mulchings of half-rotted manure on each side of the rows. This treatment is especially advisable on light, hungry soils, the plants responding quickly and producing fine crops of tender pods. Water freely during dry spells, giving occasional applications of liquid manure.

Fruit Under Glass.

Fruit Trees in Pots.—Extreme care must be exercised at this time in the watering of the various fruit trees in pots or tubs. Trees bearing heavy crops should be liberally assisted with top-dressings and liquid manure, varying it at times with chemical manure. As the fruits approach the ripening stage feeding should be withheld, as there is always a danger of spoiling the flavour of the

fruit if feeding is overdone. More especially is this applicable to Peaches in their final stages.

Vines.—In houses where the Grapes are beginning to colour a good watering with liquid manure may be given, while all superfluous laterals should be pinched off so that the berries may be induced to swell further and finish well. Where Madresveld Court is grown a certain amount of lateral growth may be allowed to remain, as this to a certain extent is a safeguard against the splitting of the berries.

Young Vines.—Encourage these to make vigorous growth by giving generous attention in the way of watering and syringing the rods. Close the house early so as to conserve sun-heat. Allow the laterals to grow freely so long as there is no over-crowding, and stop the leader when it nears the top of the house. The basal buds will then plump more readily.

The Hardy Fruit Garden.

Newly Grafted Trees.—Look over these occasionally and close up any cracks that may be showing in the wax or clay. As the young shoots on the scions begin to lengthen, support by nailing them to neat canes, which should be tied firmly to the stem or branch.

Morello Cherries.—Except where the trees are grown in bush form no summer pruning is required for Morellos. It is well known that this luscious Cherry bears its finest fruit on the young wood, but a little judicious thinning out of superfluous or weak growths will be advantageous, although the Morello will bear a closer lay in of young growths than any other wall tree. Pinch the points of the growths of trees grown in standard or bush form.

The Flower Garden.

Border Chrysanthemums.—Stake and tie beds of these in good time, as when once the growths of Chrysanthemums are allowed to fall over and get bent they never seem again to attain that symmetry of form which is necessary in the formation of a well grown plant. Hoe the ground freely between the plants and stimulate growth at the same time by giving a light dusting of artificial manure.

The Rose Garden.—Where light soils prevail heavy waterings will be necessary during lengthy periods of drought. Where liquid manure is available it should also be applied freely, more especially when the soil is in a moist condition. This feeding not only prolongs the season of flowering, but makes an enormous difference in building up strong plants for the ensuing year. Remove all faded blossoms and maintain the beds and borders in as trim a condition as possible.

JAMES McGRAN

(Gardener to Sir Henry H. Houldsworth, Bart.).

Coatham, Kilmarnock.

GREENHOUSE AND CONSERVATORY.

Aotus gracillima.—This beautiful Australian shrub is worthy of more general cultivation for the cool greenhouse and conservatory. Its long, slender shoots wreathed with small yellow flowers with dark blotches are always very much admired. It may easily be propagated now by means of small twiggy shoots inserted in pots of sandy peat, and these root readily if stood under a propagating glass in a cool greenhouse. When rooted they should be potted off singly into thumb pots, and when they are established in the fresh compost, they should be pinched once, and two or three shoots selected and run up some 24ft. high, pinching them at this height to form a head, as the beauty of this plant is best displayed when grown in the form of a small standard. The young plants should be potted on as they require it until they are in their flowering size (7in. pots being large enough for this purpose). After the first potting, which should consist of sandy peat, it is well to add some light loam to the potting compost. For the final potting it should consist of at least half loam, with the addition of good fibrous peat and enough coarse sand to render the whole porous. This is a fine plant to put out in a bed in the cool conservatory.

Prostanthera rotundifolia is another beautiful greenhouse shrubby plant which produces its small purple flowers in great profusion. It is readily propagated at this time by means of small twiggy shoots in the same way as advised for the Aotus. When stopped several times it makes a neat, bushy plant for the conservatory stage. After the final stopping some eight to ten strong shoots should be allowed to grow away for flowering. Some young stock should be propagated

each year, for when grown in pots it does not break readily after being out back. Good flowering plants can be grown in oin. pots. Planted out in a bed or border in the cool conservatory it makes a fine large bush, and stands pruning back much better than when pot grown. It should be pruned back when it finishes flowering, about the beginning of June. This plant is nearly hardy, and should be grown on a warm wall in the South and West.

Olearia Gunniana, although hardy in sheltered positions in the South and West, is, in the colder parts of the country, well worth growing for the cool greenhouse. It is easily propagated at this season by means of short, half-ripened shoots, which root readily in sandy soil under a bell-glass in a cool house. The plants flower freely in quite small pots, and should be pinched frequently in the young state to induce a bushy habit. They grow quite well in ordinary potting compost. This plant is generally known as *O. stellulata*, but differs from the latter plant in having larger and whiter flowers.

Olearia ramulosa is also a graceful and attractive plant for pot culture. Well grown examples are very beautiful with their slender shoots covered with small, starry white flowers. This plant is seen to best advantage when run up fairly tall, as the slender drooping shoots are then displayed at their best. To attain this the young plant should only be stopped twice; then about three shoots should be selected and tied up to a neat stake. Although this plant is easily rooted by means of small, twiggy shoots, it is by no means such an easy plant to cultivate successfully, as is *O. Gunniana*. It grows quite well in light, medium loam with the addition of a little leaf-soil, with enough coarse sand to render the whole porous, but it must never be overpotted, and requires careful watering at all times.

Campanula Vidalii.—This unique-looking Campanula is a native of the Canaries, and is very useful for the conservatory, as it flowers during August, at a time when it is very difficult to get a variety of interesting plants for the flowering house. This plant can be propagated by means of the side shoots, but stock is best raised by means of seeds, which may be sown at this time. As the seed is very fine, the pots should be well watered some time before sowing. The seed should be covered with a sprinkling of fine sandy soil. The young plants should be potted on as they require it, and may be grown throughout in a cool greenhouse or even in a cold frame. Although this plant will produce a few flowers in its second year, it is at its best during its third year. For this reason some young plants should be raised every year, and thus keep up a regular succession of flowering plants.

J. COURTS.

Royal Botanic Gardens, Kew

BOOKS

A BOOK ON DAHLIAS.—The Dahlia is even more popular in the United States than it is in Britain, so that it is not surprising to find that the quite bulky volume on this flower just issued* hails from across the Atlantic. Mrs. Stout has the right to be considered something of an authority on this very useful flower. She has, indeed, raised several excellent varieties. As Mrs. Stout herself points out, the Dahlia has every title to the specific name *variabilis*, for it is surely among the most variable of flowers. It is immensely affected by climatic conditions and by environment, so that varieties quite admirable here in England may well prove failures in U.S.A. Certainly many sorts highly esteemed in America have proved worthless on this side.

Much of the information given in this book is necessarily special to U.S.A., and the list of varieties is naturally quite up to date as regards American introductions and a good way behind as regards British novelties. Mrs. Stout's knowledge of the extremely popular and very promising Star class is anything but extensive. Of the later introductions to this class she seems not to have heard.

Of the raising of new varieties she writes clearly and helpfully, and her remarks on the dangers

of over-propagation are well judged and worthy of study. It is to be regretted that so able a writer should confuse *variety* with *species*. She several times uses variety improperly, as, for instance, "Three of the eight varieties of Dahlias known to grow in Mexico . . ." Another rather surprising statement is "Gravel contains no food element *nor does it hold moisture*." The italics are ours, but the statement is assuredly inaccurate.

Doubtless owing to their different (and differing) climatic conditions, the Dahlia is even more highly esteemed in the United States than with us. Assuredly it is to an Englishman somewhat surprising to see it described as "the most beautiful of all flowers." It is perhaps a little unfair to pick out the startling statements from a book of high general excellence. The book as a whole was perused with interest from cover to cover, and can be heartily recommended to all who wish to improve their knowledge of an increasingly popular flower. W.

SWISS WILD FLOWERS.—M. Henry Correvon has now published a companion volume to his "Fleurs des Champs et des Bois," which he calls "Champs et Bois Fleuris." Those who are familiar with M. Correvon's works will remember the beautiful coloured plates by Mlle. S. Rivier with which many of them are adorned. The volume under notice* has seventy-five such plates, all excellently drawn and coloured, many of them, of course, depicting wildings more or less common in our own fields and coppices. With the seventy-five entirely different plates in "Fleurs des Champs" these make an invaluable set depicting more than 200 species of lowland wild flowers.

Turning now to the letterpress, in his first chapter the author shews himself as at once an ardent upholder of the theory that real happiness is to be found only in physical endeavour. He confesses himself an uncompromising opponent of alcoholic beverages and tobacco—even of the theatre! His prescription for the salvation of the human race is work and mountain climbing! Whether one wholly agrees with the author's reasoning or not, one can but be charmed with the vigour and charm of his writing and his evident sincerity; indeed, the very real personal charm of the author—"the father," as he truly calls himself, of rock gardeners—is reflected in all his writings.

Of the body of the book with its admirable descriptions of the many species indigenous to Switzerland, it is only necessary to say that it is as lucid and as helpful as "Fleurs des Champs," and gives at some length the medicinal properties and economic uses of the plants under notice. M. Correvon has many English friends, but his knowledge of our manners and customs is evidently as yet not quite complete, otherwise he would not write that we make mint sauce with *Peppermint* or take it with roast beef! English cooking is not so barbarous. The reviewer was not aware that in this country the Bog Bean, *Menyanthes trifoliata*, is sometimes used as a substitute for Hops in beer, but it may be that it is. Tansy is, of course, so used, and M. Correvon draws attention to this also. To sum up, the book is almost indispensable to those deeply interested in gardening, botany or simples, but it is so charmingly written and so free from tables, footnotes and such-like ingredients tending to "dryness" that it makes a powerful appeal to all lovers of Nature however elementary their present knowledge.

R. V. G. W.

WINDSOR ROSE SHOW

AT the head of the Royal list of patrons of the Windsor, Eton and District Rose and Horticultural Society—to give its full title—appears "His Most Gracious Majesty the King," and one soon learns that the King is no mere titular head of the Society, for he grants permission for the annual show to be held on the slopes of Windsor Castle, gives a challenge cup for Roses that is coveted by the foremost growers in the kingdom and is also a generous contributor to the funds of the Society. It was under such high patronage and amid such historic and beautiful surroundings that the twenty-ninth annual show was held on July 1 last.

Following their great triumph at Regent's Park on the previous Thursday, when they won the championship trophy for the second successive year, Messrs. Alex. Dickson and Sons again won the King's Cup at Windsor. Their forty-eight blooms were all beautifully fresh and of splendid quality. The collection included such sorts as Archie Gray, Gorgeous, Edgar M. Burnett, Captain Kilbee Stuart, Marcella, Candeur Lyonnaise and Lady Inchquin. Messrs. F. Cant and Co., who were a good second in this well contested championship class, included characteristic examples of Gorgeous, Snow Queen, Golden Emblem, St. Helena, Mrs. G. Marriott and Mrs. J. H. Welch. Messrs. B. R. Cant and Sons were third.

As at Regent's Park, Messrs. Alex. Dickson and Sons also won the first prize for tables of exhibition Roses, and their twelve varieties were of even better quality than in the former class. Messrs. F. Cant and Co. were second and Messrs. D. Prior and Son were third.

The best twelve blooms of any H. P. or H. T. Rose proved to be a handsome dozen of Augustus Hartmann, shewn by Messrs. B. R. Cant and Sons, while Lady Ashtown by Messrs. D. Prior and Son were a close second. With beautiful specimens of Mme. Jules Gravereaux Messrs. Prior were first in the similar class for Teas, and they also won premier honours with Snow Queen and George Dickson in the class for twelve blooms each of any white and crimson Roses.

Decorative Roses set up in goodly vases are always more attractive to the general public than the show blooms on boards, and at Windsor the collections were of great merit. Mr. George Lilley had the best in the open section, while Mrs. F. W. Saunders won first place among the amateurs, and each arranged particularly beautiful vases. Mrs. Charlton, using the bright and graceful Rose Ethel James, with great taste, won the dinner-table prize.

Dr. T. E. Pallett had a great day in the Open Amateurs' Classes, for he won all three challenge cups and also first prize for twelve Tea and Noisette varieties. His collections included in George Dickson, the N.R.S. silver-gilt medal bloom, as being the best in the whole of the Show. This variety was decidedly the Rose of the Show, for it was shown in great excellence in a number of exhibits. The N.R.S. bronze medals in the local classes were won by Mr. G. A. Govett, with excellent blooms of Maman Cochet (T.) and Candeur Lyonnaise (H. P.), and by Mr. W. C. Romaine with George Dickson (H. T.), while the R.H.S. Banksian medal for the best single vase of decorative Roses was won by Mr. H. J. Stokes, with a beautiful vase of Irish Elegance. Mrs. Henry Balfour was a good winner of the first prize in the class for growers of fewer than 1,000 plants.

The Prince of Wales' Cup, offered for the best eighteen vases of Sweet Peas, has hitherto induced good competition, but this year Sir Randolph Baker had a "walk-over" with a splendid collection

and he also was similarly awarded the first prize in the class for twelve vases of Sweet Peas. In the local amateurs' classes, Mrs. V. M. Woolner won the first prize with a praiseworthy collection.

Fruits and vegetables were rather at a premium, though there were several meritorious collections of vegetables. The Sutton Special Prize was won by Mr. E. Baldwin, who had especially good Best of All Tomatoes and Sutton's Selected Duke of Albany Peas. Miss Henderson won both the Carter Special and the Society's Prizes with good collections.

The trade supported the show in a splendid manner and their excellent exhibits were a great feature. Messrs. Barr and Sons made a very attractive flower garden and Lily pool, which was greatly admired. Mr. Chas. Turner brought his customary collection of valuable hardy shrubs, many border flowers and had a delightful group of Malmaison Carnations. Mr. J. C. Allgrove set out many trained pot-grown Gooseberries and Currants and arranged a great variety of border plants, which included excellent spikes of Eremuri.

Roses were freely shewn in these honorary exhibits. Mr. E. J. Hicks had a large collection and Messrs. Waterer, Son and Crisp associated theirs with border flowers. Mr. G. Lilley contributed Roses; Messrs. J. Piper and Son included many varieties, with border flowers, and Mr. Bide set up an attractive collection of Sweet Peas.

Potatoes and Broad Beans at Reading

AT the request of the Ministry of Agriculture Messrs. Sutton and Sons allowed the expert Potato inspectors of the Board to visit their Potato trials at Reading on Tuesday, June 27. Among those present were Mr. P. G. Dallinger (Chief Inspector of the Potato Department of the Ministry), Mr. G. C. Goff (District Inspector) and Mr. G. P. Berry (Technical Horticultural Adviser). This illustrates the thoroughness and extensiveness of Messrs. Sutton's trials that they warrant the presence of the experts on the look-out for additional knowledge.

The party was first conducted by Mr. Noel Sutton through the spacious offices and gigantic seed stores. Of exceptional interest to all were the seed-cleaning machines, which were very numerous and of various designs. After viewing the seed stores the party went to the trial grounds, and were met here by Mr. Martin H. F. Sutton, who after lunch conducted them through the grounds. What interested the writer perhaps the most was the vast collection of wild Potatoes which came from such places as Chile, Peru, Mexico and Uruguay. The trials of commercial varieties included all the latest and most important varieties in cultivation, including numerous seedlings, many of which are already under trial at Ormskirk.

The inspectors were greatly impressed by the trials. The many varieties were planted early in April and others a month later. Those planted in May were infinitely better than those planted earlier.

Very interesting, too, were the new types of Broad Beans. These are the result of a cross between Sutton's Exhibition Longpod (white-seeded) and Beck's Green Gem (a rather dwarfed, small podded, green-seeded variety).

One of the new varieties is white-seeded, about 15 ins. high, of vigorous habit, and carries

a heavy crop of pods. It is dwarfed than either parent and much branched.

The other two are distinctly dwarf, reaching a height of 1 ft. only, very much branched and somewhat spreading. The crop produced is quite an extraordinary one, especially when the dwarf habit of the plants is taken into consideration. The individual pods contain four and five beans, green in the case of one selection and white in the other. The seeds are of the longpod character, intermediate in size between the two parents.

The two dwarf strains should prove of great value for early crops in frames or pits, but all the three types are also eminently suitable for culture in the open ground for the obvious reason that they can be grown closer together than is usual, while naturally they do not rob neighbouring crops of light and air to the same extent as ordinary tall kinds.

Messrs. Suttons hope that sufficient seed of the semi-dwarf and white seeded dwarf strains may be harvested this season to allow of their being offered in next year's catalogue.

Pretty Native Rock Plants.—One of the best of our native plants for the rock garden is the Horse-shoe Vetch (*Hippocrepis comosus*), a delightful trailer which will creep over the face of a rock or slope of arid, sun-beaten soil and cover either with a veil of olive green. In June the flower-stems rise an inch or so above this, each bearing a Coronilla-like head of little yellow flowers, which on passing over gives way to the seed vessel which is supposed to resemble a horse-shoe. *H. comosus* is found naturally on the limestone, but it will do in ordinary loam. It is in every respect a charming, orderly and easily satisfied plant, coming readily from seed, and the best place in any rock garden is not too good for it. There is an alpine form (*H. glauca*) with grey-green leaves which is also first-rate.

Diplacus glutinosus in the Open.—For many years this splendid plant with its aromatic foliage, elegant habit and long succession of golden buff or deep maroon flowers has been successfully grown in the open in a north-west country garden where 15° to 20° of frost is by no means uncommon in winter. The soil is light, stony and well drained, and in such a medium *D. glutinosus* will live for years without any attention beyond cutting back to the ground level (like a *Fuschia*) each spring. The shrub makes a wonderfully fast growth after this treatment and flowering commences about midsummer and continues to the first frost of autumn. Only in very severe weather is a little dry Bracken laid over the crowns. *D. glutinosus* seems to prefer a westerly aspect and, though a sun-lover, it will do very well in partial shade. Fresh plants are easily raised from cuttings struck in July, and if these are wintered in a cold frame and put out in May, many of them will flower in their first season.

Francoas as Border Plants.—Though usually seen indoors, *Francoa ramosa* and other species make first-rate border plants, the tall, branching stems (2 ft.) being rigid enough to hold erect the handsome head of white or pink Saxifrage-like flowers. Being Chilean plants, these are not necessarily as tender as many suppose. In fact, they may be grown in the open border and left without protection throughout the winter in all but our very bleakest counties. None of the *Francoas* appears to be particular as to soil or situation, but while they prefer a well drained root-run in full sun they have done successfully in quite heavy land in partial shade. The long-stemmed sprays are excellent for cutting, and the plants bloom from July on to autumn, when many flowers have gone over.

Wright Memorial Fund.—The Secretary of the R.H.S. asks us, as there is some doubt as to the purpose of the Wright Memorial Fund, to state that its object is to purchase an annuity for Mrs. Wright. It is hoped that a considerable sum will be raised in order that this may be possible.

Kew Gardens.—We understand that the five "foremen" at the Royal Botanic Gardens, Kew, Messrs. Coutts, Osborn, Irving, Raffill and Taylor, have been appointed assistant curators. The title "foreman" certainly was open to improvement, as, to the uninitiated, it conveyed a totally wrong impression of the responsibility of the position.

Classification and Synonymy of Crocuses.—The Royal Horticultural Society is desirous of planting all available species and varieties of Crocus for purposes of comparison, and the Director, R.H.S. Gardens, Wisley, Ripley, Surrey, will be glad to receive examples for the purpose so far as possible by July 31, 1922.

A Trial of Lettuces.—The Royal Horticultural Society will carry out a trial of autumn-sown Lettuces in their Gardens at Wisley this season. A packet of seed of each variety to be tried should be sent to reach The Director, R.H.S. Gardens, Wisley, Ripley, Surrey (from whom the necessary entry forms may be obtained) on or before July 31, 1922. Only varieties suited for autumn sowing should be sent.

An Excellent Spraying Syringe.—The Editor has recently had under trial one of the Abol Company's spraying syringes, special features of which are the anti-drip collar—a great boon to the amateur—and the fine, medium and coarse nozzles which enable the fineness of the spray to be regulated for various purposes. To clear the nozzle should dirt enter the syringe is the work of a moment, and the spray is very evenly distributed. For damping flowers to keep them fresh during transit or otherwise the fine jet is splendid. These syringes, which are recommended to members by the National Rose Society, are made in several sizes with or without the useful angle joint. Those in search of a first-rate syringe will find it in the Abol.

Netting Supports for Wall Fruit.—Many visitors to the Summer Rose Show were attracted to the new "Everyman's" netting supports exhibited for the first time by the House and Garden Sundries Company. These consist of a strong wire bracket to support canes in a manner similar to their well known netting supports for seed and Strawberry-beds, etc. The upper arm, which rests on the top of the wall, is provided with two loops through which any ordinary iron nail of sufficient length may be driven. A smaller loop at the lower arm gives the necessary support. These nails are driven into the mortar between the joints or suitable nails can be driven into the brick itself, the netting being fastened along the top of the wall by a series of hooks (the "Everyman" patent wall clips are admirable for the purpose), is brought forward over the canes and hangs down, thus projecting about a foot from the wall, so holding the netting clear of the fruit trees and giving space for foliage and fruit. The lower end of the netting can very quickly and conveniently be secured to the ground by means of the special netting pins also supplied by the firm. When not required for use netting and canes can be very easily and rapidly detached from the supports, and when stowed away occupy very little space. The brackets themselves are galvanised after manufacture, which protects them from rust. The netting pins referred to are also galvanised after manufacture, and are well adapted to their purpose. Made to the same pattern but a size smaller are excellent layering pins, equally useful for Carnations, Pinks or Strawberries. They are so shaped that the top

of the pin remains in sight when the layering is completed and so may easily be released at the proper season.

FORTHCOMING EVENTS.

July 18.—Durham, Northumberland and Newcastle-on-Tyne Horticultural Society's Annual Show (3 days).

July 20.—Walsall Horticultural Society's Show (3 days).

July 21.—Birmingham Horticultural Society's Show (2 days).

July 22.—Caterham Horticultural Society's Show.

ANSWERS TO CORRESPONDENTS

FLOWER GARDEN.

ANTIRRHINUMS DYING (K. L., Sussex).—The Antirrhinums are attacked by the fungus *Phyllosticta antirrhini*. They should be destroyed as they are not likely to outgrow the trouble and if left they may be a menace to the same type of plant next year. Antirrhinums do not require "stopping" if they are not allowed to become lanky in the seedling boxes.

IRISES ATTACKED (A. E. L., Taverley).—We expect that our correspondent's Irises are attacked by the Iris rhizome rot and recommend him to remove the diseased parts and give the soil a dressing of superphosphate of lime at the rate of 2ozs. to the square yard.

LUPINUS ("Mauve Poppy").—The little swellings on the roots of the Lupinus are not the sign of a disease, but of the presence of beneficial bacteria that take nitrogen from the air and pass it on for the use of the plant. They enrich the soil by this work for plants that follow after and are encouraged, therefore, by farmers and others by growing plants belonging to the family Leguminosae.

THE FLOWERING OF RANUNCULUS ALPESTRIS (D. C. M.).—This white flowered Buttercup prefers chalky soils, and grows on mountains between 3,600ft. and 5,400ft., occasionally going a little higher. It flourishes in fallen debris, in moist chinks of the rocks, and among the cool grass, and blooms from June to August in its native habitats. The difficulty in growing it in the more southern and warmer parts of this country is due to the warmth and dryness of the atmosphere during its period of flowering, as well as before and after that. To overcome this difficulty it should be planted in a cool situation, facing east or north, or simply shaded from the south by a tree, wall or other object. Water should be given to keep it regularly moist all through the growing season. The soil may be deficient in lime, and chalk or old mortar would meet this. It is possible to resuscitate old plants by giving them cool and moist treatment, with some lime in the soil.

IRIS QUESTION (Folsted).—There are no English Irises identical, as far as colouring goes, with the Spanish Irises *Cajanus* and *L'Unique*, nor are we acquainted with any Dutch varieties that would meet the case. Yellow colour (as in *Cajanus*) does not occur in English Irises, and the particular blue and white of *L'Unique* is very difficult to match exactly. The nearest English Iris, so far as we know, is either *Matador* or *Prince of Wales*, but the shade of colour rather lies between the two. The nearest to the rich golden colour of *Cajanus* in the Dutch Irises are probably *Golden Glory* or *Van der Heest*, though the precise shade is perhaps more nearly matched in *Iris Moonlight*, which, however, is not a bulbous Iris and, unless it can be given a very sunny position, does not always flower regularly, but it is a glorious species, and well worthy of additional trouble and care.

RABBITS AND IRISES (H. W., Wirksworth).—Rabbits destroy a great variety of plants and in warrens, where there is little grass, they will eat Gorse and Froom to the ground line. In one case where they got into a flower garden they gnawed and damaged the Zonal *Pelargonium* in the beds. Where grass is plentiful we have not observed much harm to things in general. They are fond of Carnations, Pinks and Laburnums, and will dig out these in preference to most other plants. We have seen about an acre of Irises near a large pond and at a considerable distance from houses, yet failed to see any damage by rabbits and heard no complaints. Judging by this the rabbits are not so fond of Irises as to single them out for special attention, and if grass is plentiful we think that damage to Irises would be negligible.

ROSE GARDEN.

ROSE COMPARISONS (Folsted).—The two Roses—W. C. Clark and *Château de Clos Vougeot*—although both dark crimson in colour, are quite distinct. W. C. Clark is much more shaded with maroon, is a better-shaped flower, is more fragrant, and is decidedly a stronger grower, so that, unless there is some special reason to the contrary, it is to be preferred to *Château de Clos Vougeot*. W. C. Clark also surpasses in all respects *Captaine Georges Dessirrier* which was considered by the raiser to be an improved *Château de Clos Vougeot*.

TREES AND SHRUBS.

AUCUBAS AND RHODODENDRONS UNSATISFACTORY (A. B., Woking).—The Aucubas and Rhododendrons are both suffering from the drought. Neither is

a plant for a very sunny position and Rhododendrons especially object to it. It is surprisingly difficult to wet soil when once it has become dry as we fear our correspondent's Rhododendron soil has.

FRUIT GARDEN.

RASPBERRIES NOT FRUITING ("Raspberry").—We can find no fungus or insect to account for the failure of the Raspberries. They may have been attacked by a little rusty brown beetle which often eats the stems and tends to prevent fruiting.

STRAWBERRY PLANTS UNSATISFACTORY (H. F. M.).—We have carefully examined the Strawberries sent for examination and find neither fungus nor insect present in them to account for the failure of the plants. The roots, however, are not healthy, and we wonder whether the soil is kept well hoed and free from stagnant moisture. Deep digging after the plants are in, of course, dangerous and so also is too hot an exposure of the soil. It would be worth while to attend carefully to such points as these and to make a bed on another spot.

CHERRY TREE UNSATISFACTORY (Hampton Court).—It is very likely that the blossoms were frozen. This does occur in some seasons and, curiously enough, portions of the trees are affected while others are not. Afford some protection to the blossoms another year. As the tree is very healthy, beyond the necessary pruning and a surface mulch of lime and loam—2 pecks of lime and 5 pecks of loam—next winter, there is nothing to improve the tree and its fruitfulness.

LIFTING AND PLANTING APPLE AND PLUM TREES (H. D. M. T.).—It would not answer at all to lift the trees in October and endeavour to keep them with their roots wrapped in straw sacking and earth. They would live, certainly, if lifted and well heeled-in, then replanted next April; but the check would be very severe. We advise our correspondent to do one of two things, namely: sell the trees to someone who would be able to re-plant them at once and permanently next October, and buy young trees to plant in November, 1923. Or arrange with someone to replant the trees, forthwith, in their garden in October and leave them there till the month of November, 1923, then planting in your own quarters.

HOW TO MAKE STRAWBERRY NETTING WATER-PROOF (A. B. P.).—The following process will make the string netting waterproof for at least two years. Five pints of linseed oil, 2ozs. of sugar of lead, 6ozs. of white resin. Simmer or boil gently the above ingredients in an iron pot over a slow fire for twenty minutes or half an hour. Apply in one of two ways, namely, by painter's brush while the liquid is hot, having first stretched the nets out fairly tightly to posts or outbuildings, or dip the nets in the hot liquid and then stretch them out to dry. Mix the ingredients thoroughly in the pot before placing the latter on the fire and stir slowly while the boiling is going on. Dip or paint the nets twice, but in the case of dipping be sure to lift out the net before the liquid cools too much.

PEAR TREE UNSATISFACTORY (P. B. H., Bourne-mouth).—The variety, Gansells Bergamotte, is a shy one in the matter of bearing and answers best when double-grafted. It is also assisted if very free-setting sorts are growing near: A cordon or two, of the variety *Durondeau*, planted conveniently near would help matters and the latter sort would rarely fail to bear some wood freely it would be beneficial if our correspondent root-pruned the tree next November or during December. Take out a trench 18ins. wide, 4ft. from the stem and about 2ft. deep. Cut off all fibrous roots crossing the trench, fill up with good loam and make it firm. Summer prune the tree now and winter prune in due course.

KITCHEN GARDEN.

ASPARAGUS BEDS (Bronley).—Do not use salt on the Asparagus beds till growth begins next spring, it would not benefit them. Keep the beds quite clean and water freely with such diluted liquid manure as that from a farmyard. Do not continue to cut Asparagus after the first week in July, at the latest.

CLUBROOT IN CABBAGES (A. B., Woking).—Cabbages become clubbed because of the attack upon them of a slime fungus (*Plasmiodiophora brassicae*). The only remedy is a dressing of quick lime, and this should be applied in autumn in a powdered state and dug in immediately, but not buried deeply. The presence of club root is a sign of soil sourness.

MISCELLANEOUS.

IMPROVING TENNIS LAWN (Bronley).—Undoubtedly our correspondent's lawn is poor and the grass needs stimulating. During the summer months get rid of the coarse weeds by dropping oil of vitriol in the centre of each weed such as the Plantains; use gloves and a pointed and slightly notched stick when applying the vitriol; dip the point in the vitriol then gently force it into the heart of the plant, which will soon die. Keep the oil of vitriol locked away in a safe place, also the implement with which it is applied. Early in September have ready some sifted rich soil, mix it with ground lime, one barrow-load to four of the soil; apply as a liberal surface dressing. A fortnight afterwards sow seeds of Hard Fescue Grass and roll the lawn. Next March repeat application and the sowing of the grass seeds.

NAMES OF PLANTS.—J. C., Shrewsbury.—1, *Brodiaea laxa*; 2, *Senecio Smithii*; 3, *Rhus Cotinus*, "Smoke Plant"; 4, *Abelia tricolora*.

COLESBORNE, GLOS.

**IMPORTANT SALE of CHOICE HYBRID
NERINES, AMARYLLIS, PANCRATIUM,
ORCHIDS, and other Plants.**

By Order of H. J. ELWES, Esq.

Messrs. PROTHEROE & MORRIS

Will Sell the above by Auction on the Premises,

COLESBORNE PARK,

On TUESDAY, AUGUST 1st, 1922.

Plants may be viewed by appointment. Catalogues on
premises, or of the Auctioneers, 67 & 68, CHEAPSIDE
LONDON, E.C.2.

BLOM for BULBS

GREATLY REDUCED PRICES.

Catalogues Free. Apply to **WALTER BLOM & SON**, Overveen, HOLLAND;
or to **Messrs. NEALE & WILKINSON, Ltd.**, 16, Camomile St., LONDON, E.C.3.

DECORATIVE RAMBLING ROSES FOR HOUSE AND GARDEN

THERE are probably no Roses which make so brilliant a display in the garden as do the hybrid Wichuraianas and the climbing Multifloras. From the point of view of this article, namely, their decorative value, I need not rigorously discriminate between the two classes.

Turner's Crimson Rambler, introduced in 1893, was, so far as I know, the first of the Climbing Polyanthas grown in England. It quickly found its way into almost every garden. It is a Rose to which "distance lends enchantment." Seen near at hand the bunches of blossom are too heavy and crowded, and the colour is a little crude. In the distance, especially with the sun shining upon them, they make a fine splash of decided colour. As cut flower I cannot recommend them.

In 1897-98 Mr. N. J. Manda of New Jersey brought out the two fine hybrid Wichuraianas and called them Manda's Triumph and Pink Roamer. Though poor things in themselves, they were the pioneers of a great race, and were followed in 1899 by the beautiful yellow varieties Albéric Barbier and Gardenia, still two of the best yellows. In the same year Manda introduced the single creamy yellow Jersey Beauty with evergreen foliage.

In 1901 Messrs. Perkins and Jackson may be said to have revolutionised the appearance of our Rose gardens by bringing out the much loved, and of late much abused, Dorothy Perkins. No doubt her arrival, quickly followed, as it was, by other brilliantly coloured varieties, marks a distinct advance in the decorative value of the Rose as a garden plant.

For screens, tall hedges or pergolas the Wichuraianas are the most effective of all climbers, and they have what for these purposes is very desirable, an exceedingly rapid growth. They are also excellent for tall pillars. When grown as pillars all the old wood should be cut away as soon as they have finished flowering and the young growths should be carefully tied up to the pillar. This allows the sun free access to the plants and helps to ripen the new wood, from which very fine blossoms should be obtained the following year. If the plants are to cover large buildings or to make a big hedge or screen, some of the old wood with the best of the new growths or "continuing laterals" may be left in the autumn, only the dead and weak wood being taken right out. In the following spring these laterals may be cut back to a few buds or "eyes," when they also should produce quite fine clusters of bloom. There are now such a large number of varieties, all in their way decorative, that it is impossible

to make a complete list, but I will mention a few in their different colours which we have found the most effective.

WHITE.—Sander's White (late) and Grüss an Zabern (early). These have clusters of small flowers. The most beautiful of the white varieties with large fragrant flowers and very strong thorny growth is Purity. It is delightful cut in long sprays and loosely arranged in tall glass vases.

YELLOW.—Gardenia, Albéric Barbier, Shower of Gold and Emily Gray. Of these Albéric Barbier is one of the most delightful when cut, as the yellow buds open to rather large, creamy flowers which last a long time in water and are very fragrant. Emily Gray has flowers considerably larger than those of most of the "Wichs" and very handsome foliage, but it does not make big clusters. It is the deepest of the yellows. Jersey Beauty has single flowers and very large evergreen foliage.

PINK.—There are a large number of excellent pink varieties, some of which are sports of Dorothy Perkins. Chatillon Rambler, deep pink; Minnehaha, deep pink; Lady Gay, deep pink; Lady Godiva and Dorothy Dennison, pale creamy pink. The two last named are often considered identical, but in this garden we have found Dorothy Dennison the better of the two on account of its greater immunity from mildew. Cut in a young state the flowers last quite a week.

ROSE PINK.—American Pillar is one of the most effective of all the Ramblers, with huge clusters of single flowers. Ethel has erect trusses of pretty, almost single, flesh pink blossoms; while Christine Wright has large bright pink flowers.

SALMON ROSE AND COPPER.—Among these

ROSE ALBERIC BARBIER AND FOXGLOVES.

ROSE TEA RAMBLER.

ROSE GARDENIA AS A WILFING STANDARD.

shades of colour François Jurauxville (very sweetly scented), Léontine Gervais (with exquisite orange-tinted buds), Tea Rambler and René André are perhaps the best.

Evangeline, single flowered, pink, with a white centre not unlike our English Briar Rose, is worth growing for the sake of its delicious fragrance, which on a warm July evening fills the garden with its sweetness.

Joseph Lamy, white, edged with soft blush pink, is less well known than it deserves to be. It is not so rampant as most of the "Wichs." For some positions this may be an advantage, and its delicately tinted flowers have a refinement lacking in some of the more flaunting varieties.

CRIMSON.—Coronation is the brightest crimson we have with the exception of Paul's Scarlet Climber mentioned in my last article (July 8 issue). This is undoubtedly the finest crimson pillar Rose yet brought out, and the blossoms last in good condition longer than those of any other variety. They come on smooth almost thornless stems, therefore in many ways it is an ideal Rose for cutting. It is, however, quite scentless. Hiawatha (crimson with white eye, single flowered) and Excelsa (with huge bunches of crimson flowers) are two of the best in this colour. In driving about the country during July and August one cannot help noticing the popularity of these two varieties, almost equalling that of Dorothy Perkins. They seem to be taking the place of the older Crimson Rambler. They are brighter in colour and are less given to mildew. Diabolo is a nearly single "Wich." of a very rich crimson shade with bright golden anthers.

A Wichuraiana of a different character from most of the above is Gerbe Rose. It is not specially rampant, but it has beautiful light green foliage and smooth stems. The pale pink, very fragrant blossoms are arranged along the stems in the fashion of a wreath, hence the name. The flowers are produced in the autumn as well as the summer.

From the point of view of the decoration of the house many of the climbing Roses are exceedingly useful, although to me they have not quite the charm for this purpose that the more beautifully formed Teas and Hybrid Teas possess. They are, nevertheless, extremely effective when they are arranged in tall vases, and even the tender-hearted can cut them with long sprays without compunction. Many of them as we have seen are fragrant, and nearly all have the great advantage of lasting well when cut. Léontine Gervais with its pretty orange buds and bright shining foliage makes a delightful table decoration, and for this purpose the single Jersey Beauty and the creamy pink Dorothy Dennison are also very well suited; in fact, in skilful hands and used with moderation these Rambling Roses may add much to the attraction of our houses, as they undoubtedly do to our gardens.

WHITE LADY.

POSITIONS FOR WICHURAIANA ROSES

The hybrid Wichuraianas are probably the easiest to grow of all hybrid garden Roses. They flourish on light, not over-rich soil, which, without considerable alteration and improvement, would be quite unsuitable for the beautiful Hybrid Teas and even more impossible for the Hybrid Perpetuals. Easily increased from cuttings and for the most part vigorous in growth, whether on their own roots or budded on the Briar, their ease of culture often leads to their being planted in quite unsuitable situations.

It borders on the banal to point out that some varieties shew more of Wichuraiana blood than others, but it is this fact, obvious though it be, which leads to mistakes at planting time. Rosa Wichuraiana itself has exceedingly glossy foliage. It is followed in this respect by most of its descendants with yellow or creamy flowers, such as Albéric Barbier, Klondyke, Jersey Beauty or Gardenia. On the other hand, varieties with pink or crimson blossoms in clusters, such as the Dorothy Perkins group, Troubadour, Hiawatha, etc., have foliage noticeably less glossy and, incidentally, less beautiful.

It is quite safe to use Roses belonging to the former class to drape a hot bank with a southern exposure. They may either be planted at the top and allowed to trail down or planted at the bottom and trained up. In either case they are unlikely to be troubled with red spider or badly attacked by aphids. Dorothy Perkins, however, despite its robust constitution, will not flourish under such conditions. It may grow, for it has immense vitality, but it will almost certainly become infested with red spider. If a pink Rose is wanted for such a position, it will be wise to fall back upon the more truly beautiful but less spectacular René André, which has a dark glossy foliage so characteristic as to identify the variety even when out of flower.

It must always be remembered that Rosa Wichuraiana is a trailing species and that most of the hybrids are happiest when allowed to trail.

BORDER CARNATIONS AND THEIR PROPAGATION

Their merits and increasing popularity, with some recommendable varieties.

SMALL wonder, when we consider their many charms, that Carnations, "the fairest flowers o' the season," as Perdita so rightly described them, have long had a warm place in the hearts of the English people. Not only have they been beloved alike by peer and peasant, but kings have paid homage to their beauty and delicious fragrance. A portrait of King Edward IV, painted in 1467, shews him holding a red Carnation, and this royal predilection is shared by our own King George, who at the Chelsea Show of 1921, when he saw Mr. Douglas's collection of most magnificent flowers, remarked, with great enthusiasm, to Her Majesty and to Lord Lambourne, on his great love of Carnations.

Such perfect blooms as those shown by Mr. Douglas are not possible with all of us, and the blooms in question must have been pot grown, but in the generality of gardens it is not at all difficult to grow Carnations really well. They also have the merit of being good town plants. But, as with so many other plants, success is only attained by care and timely attention to cultural details. Now, while the plants are in full bloom, it should be decided what sorts are to be perpetuated and what new varieties purchased in order to keep the collection as up-to-date as possible. In the matter of propagation the old-time florist mostly pinned his faith to pipings, which, they said, produced sounder plants that "will encounter the rigours of a sharp winter better." But most of these fanciers grew their plants in pots, so it is not likely that they possessed such sound constitutions as have our present-day Carnations, which may well be propagated by the easier method of layering.

The layering should be done as soon as the "grass," as the basal shoots are termed, has grown long enough to be treated, and it will generally be found that this happens towards the latter part of July. The work can well be done throughout a month from that time. The earlier the shoots are layered, however, the better will the next season's flowers be. As it will be a considerable time before the plants can be copiously watered, once layering has been commenced, it is well to make sure that the soil is thoroughly moist before commencing the work. Layering is quite a simple operation; the "points to be observed" are: select a good healthy growth, cleared of its lower leaves and cut well along the

centre with a sharp knife, the layer to be well pegged down in sufficient sifted, leafy soil; the soil surrounding the layered shoots to be left uniformly moist. When removing the basal leaves, care must be taken not to strip the skin from the shoot; if the leaves do not pull away cleanly, a pair of scissors should be used. It will be found that a worn-out birch broom will furnish a number of suitable pegs for the layering, while

BORDER CARNATION, CRYSTAL CLOVE, HAS THE TRUE OLD CLOVE SCENT.

in country districts many use pegs cut from bracken fronds.

During the long period that the Carnation was grown as a florists' flower, form and ground colour were much more esteemed than fragrance, but now, while a well formed flower is still rightly admired, it is held in greater esteem when it possesses that precious gift of fragrance. The most fragrant of all Carnations—the old Clove Carnation which formerly was in nearly all gardens—seems now to have totally disappeared, but that beautiful variety Bookham Clove more nearly approaches it in perfume than any other sort and is quite the best of all the crimson Carnations. It has long been known that the crimsons and scarlets are distinctly more fragrant than those of any other colour, so those who prize fragrance above all will also grow such as John Knox (a deep velvety crimson flower), Mrs. A. Brotherston (white ground,

heavily marked with crimson-purple), Jean Douglas (vivid scarlet), with Cardinal (light scarlet), Golden Douglas (the best bright crimson), and Lullaby (the best of the bright scarlets). Or the pinks—Rosy Morn, Mrs. Robert Gordon, Miss Willmore and Hilda Blick are all beautiful and reliable, and of the blush pinks Innocence, Annie Laurie and Lady Roscoe are as good as any. From the apricot-shaded sorts one would select Elizabeth Shiffner, Salmonca, Mrs. G. A. Reynolds and Dora Blick. Bookham White is the best of all whites, though Mrs. Henwood and Trojan have also great merits. Daffodil and Border Yellow, with the ruby-coloured Lord Nelson, and Grey Douglas and Duchess of Wellington, from those of heliotrope shades, with the above, would make a good selection of self-coloured varieties. There is now quite a strain of Clove-scented sorts, including the pure white Crystal Clove and the beautiful Salmon Clove.

The Fancy Carnations are increasing in favour now that it is realised how very beautiful many of them are and what wide ranges of colouring they possess. A good selection would include The Bride (rosy red on white ground), Delicia (pink and crimson on white ground), John Ridd (yellow suffused with rosy red), Mona (buff, suffused with pink), Mrs. H. L. Hunt (lavender on white ground), Liberté (maroon and crimson on rich yellow), Mellon Prior (glowing scarlet on rich yellow), Harlequin (rose and crimson on canary yellow), Daisy Walker (rose pink on white ground), Lord Kitchener (bright red on glistening white), Pasquin (yellow ground edged and flushed with rosy-lavender).

Picotees have a distant charm and while it is rather difficult to grow the ideal, perfect flower, they are exceedingly graceful and decorative. They are divided into yellow ground and white ground sections. Each section has varieties with a broad, medium or light edge. In all varieties the ground should be clear and unspotted. The following is a good selection of yellow ground Picotees: Agnes, Exquisite, Togo, Constance, Santa Claus, Margaret Leinox, Onward and Ophir; while Gannymede, John Smith, Radiant, Polly, Brunette and Mrs. Sharp are good white ground sorts.

The new Perpetual Border Carnations, which have been shown so consistently by Messrs. Allwood Brothers, have great possibilities. The raisers claim that they will surpass the true Border varieties, as they flower perpetually from late spring to late autumn. In growth and habit they are much like the Border varieties and to this charm of foliage they add the long period of flowering derived from the Perpetuals. The best of these sorts are Avondale (rich salmon pink), Brilliant (white ground, heavily edged and flaked with chocolate), Highland Lassie (white ground, edged with red), Rosalind (heavily pencilled with red on white ground), Sussex Pink (delicate peach, deepening in the centre), and Sussex Maid (flaked with rose pink on white ground).

A. CECIL BARTLETT.

FORTHCOMING EVENTS

July 25.—Royal Horticultural Society's Fortnightly Meeting. Lecture at 5 p.m. by Dr. A. B. Rendle on "Plants of Interest Exhibited."

July 26.—Cardiff County Flower Show (two days).

July 27.—Royal Botanic Society's Meeting, Bristol and District Gardeners' Association's Meeting.

July 28.—Midland Carnation and Picotee Society's Exhibition (two days).

July 29.—National Viola and Pansy Society's Show, to be held at the Botanic Gardens, Birmingham.

ESSENTIALS OF GARDEN DESIGN

II.—Unity and Gradation

OUR first article was devoted to the importance of Simplicity. Of two ways choose the simpler. Let us this week consider the closely related principle—Unity. How often after visiting a garden does one speak or think of the component parts or some of them rather than of the whole. "Mr. So-and-so has a charming rose garden" or "lovely water garden," as the case may be. Such gardens, most of us think, just miss greatness through a lack of homogeneity—for want of a settled plan or, it may be, for lack of a competent planner!

It may disarm criticism to say at once that not everyone likes a planned or ordered garden, or planned or ordered house for that matter. Lovers of the heterogenous in architecture will like the scattered and haphazard in garden construction. Their gardens, like Topsy, will have "grown"—grown awkwardly at that, an outgrowth here and an extension there, the whole reminding one of a supertuberculated Potato. These notes are not for such, so they had better turn the page.

Unity is chiefly manifested in the connexion of the various features. Obviously it is easier

the straightness in the formal garden. On the other hand, a severely formal garden is more difficult to connect to purely informal planting because the two have no feature in common.

It would, in fact, be true to say that some feature in common must be provided if a satisfactory junction is to be effected. Such feature may be nothing more than an unbroken stretch of greensward, the common groundwork of formal and informal alike, or, if paving be employed in the formal garden, a line of paving leading onward into the informal garden will often establish a unity that was previously entirely lacking.

We all know the more or less "picturesque" type of building either designed by some architect of the last generation or, occasionally, formed by the addition, at odd periods, of wings, single rooms, porches and what not. To-day such buildings are not greatly favoured. Not only does their architecture lack distinction, but they are, as a rule, singularly inconvenient within—often, indeed, lacking some of the more elementary conveniences one is entitled to expect.

While the "picturesque" and higgledy-piggledy in architecture has gone into disfavour, the higgledy-

and, as a rule, makes no attempt to visualise the completed scheme. He may possibly enlist the services of his house architect to design a surround. The result, in this case, is but too likely to be the same. A house architect usually considers garden-design as a very subsidiary portion of his duties, and, at any rate, he lays out the surround only from the point of view of shewing to best advantage the house architecture. The immediate surround of the house, however, forms the connexion between house and garden and needs thus to be thought of from two aspects.

How often does one see what should be a straight herbaceous walk, leading on, perhaps, to further gardens or it may be terminating in some architectural feature, swerve like a shying horse towards the end because, probably, lack of foresight has made the proper connexion impossible. It is not always, of course, that such ineffective paths and strange, inconsequent awkward joinings are caused by the impossibility of getting better effects. Sometimes it is merely that, through slight acquaintance with the subject, the right solution is passed over.

There can be little sense of unity in a garden where the connexions between various features are "hole and corner." On the other hand, let no one confuse unity and monotony. A garden springs to mind—a garden of some extent—largely consisting of winding walks planted on either hand with flowering trees and shrubs and hardy plants. Similar trees, shrubs and plants were to be found in each section, and the owner and his head-gardener were pleased to speak of the "essential unity" of the design; "deadly monotony" would have been the writer's description.

Unity and simplicity in a garden are so closely intertwined that it is difficult at times to differentiate; the same may truly be said of unity and gradation. The unity and completeness of a garden largely depends upon proper gradation. It must always be right to have the most formal treatment nearest to the house and the most informal at a distance from it. To obtain a satisfactory and pleasing effect the gradual merging of the formal into the informal must be managed, and this is admittedly most difficult when the house calls for very formal surroundings and the space at disposal is limited. In such case it is often better to eschew informal effects altogether.

There are, throughout the country, many gardens which it is a real pleasure to view, where excellent plants are grown, where the arrangement and proportioning are in every way satisfactory, but which from the owner's standpoint are, nevertheless, open to grave objection because the view of the gardens from the house is unsatisfactory or, in some cases, there is practically no garden view from the house at all. The garden is, after all, merely the setting for the house, and it is, assuredly, a very grave drawback if it fails to provide a series of beautiful views from the principal points of vantage in and around the house itself. There are, of course, houses where, owing to various extraordinary conditions, such views may not be, but they represent but a very small proportion, and the appearance of the garden from various windows and entrances should certainly be the would-be designer's first care.

The normal sequence of gradation between formal and informal may be expressed as follows, commencing with the house-surround:

(1) Entirely formal—rectangular paving, formal beds, mown level lawns, dressed stone walls, moulded copings, carved pillars, caps, urns or stone vases.

(2) Rectangular paving, either "coursed-random" or "rectangular-random"; probably

A GARDEN WITH MANY AND VARIED FEATURES.

From formal pergola and rose garden, one traverses a bold curving vista which might in itself incorporate a great number of features such as wild rose, rhododendron, azalea, heath and shrub gardens. Suitable plantings elsewhere will readily suggest themselves.

satisfactorily to connect features presenting points of similarity than those entirely dissimilar. Formal rose garden and pergola are readily linked, because both are formal and both make Roses a main feature; pergola and summer-house or pavilion, because both are architectural; a straight herbaceous walk and any sort of formal garden, because the straightness of walk and borders conforms to

piggledy and assuredly unpicturesque in garden lay-out still lingers. The reason for this is sufficiently obvious. The owner of a new house usually, in the first instance, lays out only the ground immediately around it. He is absorbed in the details of the house itself. Consequently when he turns to the question of the house surround he gives it more or less perfunctory attention

THE CARE OF HERBACEOUS BORDERS AT THIS SEASON

self-faced and possibly with Thymes and other low-growing plants between the joints; walls of undressed stone, either coursed or rectangular-random; simple un moulded copings, mown level lawns and terrace banks; formal beds with informal plantings, probably mounding on or trailing over the pathway stones.

(3) Formal hedges, formal beds, stone seats, etc. If carried out in the grand manner may be as formal as or more formal than (2).

(4) Formal hedges, regularly arranged curvilinear beds, possibly on sloping ground.

(5) Straight herbaceous walks and straight-edged shrubberies.

(6) Beds of curvilinear outline, the curves free and dissimilar, but all defining a straight or easily curving vista.

(7) Similar work, but contoured, with the probable introduction of rockery stone.

(8) The entirely informal wild garden.

This does not precisely describe, of course, every desirable style of garden, but it will not be difficult to place any such as about equal in formality to one or other of the above. Between (6) and (7) some would place gardens with beds bounded with free and dissimilar curves, but giving no vistas. These are omitted as unworthy. Such gardens must lack essential combination.

It is hardly necessary to point out that all the above gradations need not be present in the same garden to shew satisfactory design. Only with Classical or Renaissance architecture of some pretensions is the purely formal style (No. 1) necessary, while in grounds of limited extent there is no scope for wild gardening and, maybe, no place even for the balanced, informal masses described in Nos. 6 and 7.

Speaking generally, it is undoubtedly a mistake especially in the gardens of limited area which are being formed to-day, to pass, as one leaves the house behind, from formal planting to informal and then revert to the formal once more. It is, however, allowable, even necessary in many cases, to reintroduce a degree of formality around a pavilion, summer-house or other architectural feature closing a vista. For this reason, if for no other, the architecture of such garden building should be as simple and unaffected as possible. An austere Georgian house—and some Georgian houses may accurately be so described—with modern garden architecture, including elaborate pillars in one or other of the recognised orders and ornate cornices and other mouldings is a truly pitiable combination.

Gradation is, of course, important as applied to the actual planting. There must be gradation of mass and gradation of colour if the result is to be satisfactory. Gradation in planting is, however, a subject of great importance and some complexity and may more fittingly be dealt with when we come to discuss "Balance," which it is hoped to do in a subsequent article. Gradation in colour planting is also altogether too big a subject to include in the present article.

The plan on page 354 shews a method of treatment not feasible in every garden. It could, obviously, not be carried out on a site greatly longer than wide, for instance. It serves, however, to suggest how unity may be maintained in a garden displaying a wide variety of plants and treatments and also how a pleasing gradation may be managed. The association of pergola and rose garden will be noted, also that the pergola is definitely supported by architectural features—the house at one end and a summer-house at the other. There are few commoner mistakes in the garden lay-out than the wrong use of the pergola. A pergola which seems to have no definite objective always looks out of place.

UNLESS care be taken, herbaceous borders are but too apt to become untidy and unsatisfactory as soon as the Delphinium blossom is over, if not before. The copious rains which have supplied sadly needed moisture have also in many cases laid low the occupants of the border, even

the clumps. Plants from seed have usually sufficient vigour, given good soil and cultivation, to make the double effort without loss of stamina and this is undoubtedly the reason why in many gardens in which only the best is good enough, seedling Delphiniums are chiefly to be met with in the herbaceous border.

EFFECTIVE HERBACEOUS BORDERS.

where staking and tying had been thoroughly and intelligently carried out.

The havoc having been, as far as practicable, repaired, remains to hoe or otherwise break up the surface of the border and apply a mulch of rotted manure or even lawn chippings so that the moisture may be conserved in the very possible spell of hot weather. If the border has been planted to advantage, most of the gaps caused by the passing of early-flowering plants may be largely concealed by judicious "tying out." There will, however, always remain some gaps which may not satisfactorily be filled by this method.

This is where the value of plants grown on in the reserve garden becomes apparent. Many Michaelmas Daisies and a number of sorts of border Chrysanthemum will lift quite well, if thoroughly soaked two or three days previously. If Michaelmas Daisies belonging to the *Novae-Angliæ* class are wanted, however, they must be grown plunged in large pots as they do not transplant satisfactorily from the open ground. The same remark applies to the more tap-rooted Chrysanthemums. There is an enormous difference between varieties in this respect.

It is becoming increasingly the custom to plant out Dahlias of all the decorative classes to "carry on" after Lupins, Dornicums, Anchusas and such like have finished. It is quite possible to use them after Delphiniums and other flowers of full summer. They, too, must of course be grown in pots.

Delphinium plants, if cut back immediately after flowering, will produce a second and very welcome crop of bloom in autumn. Many amateurs have cut them back, however, who have subsequently regretted doing so, for, especially in the case of named varieties, it has a very weakening effect upon

Undoubtedly the average man when forming his herbaceous border uses too large a proportion of plants of short duration. Some of the grandest flowers, unfortunately, produce the shortest display; think of Lilies or Gladioli, for example. The following plants have a long flowering season and should be used for some of the largest groupings. Unfortunately, they are all comparatively low-growing. *Geum coccineum*, all forms, including the Winchmore Hill variety, now called Mrs. Bradshaw, must first be mentioned, then Gaillardias—the soft yellows, such as Lady Rolleston or E. F. Anderton are invaluable—*Nepeta Mussini*, *Anthemis Cupaniana*, *Cercopsis grandiflora*, Iceland Poppies (if the seed pods are removed) and *Violas*, many bedding varieties.

Quite a number of plants, of which the flowering season is short, are decorative when out of flower and so merit special attention. These include the herbaceous *Paeonies*, the Bearded Irises, many French Lilies (*Kniphofia*), the Day Lilies (*Hemerocallis*), the Globe Thistle (*Echinops Ritro*), and some of the *Thalictrums*, as well as such generally used shrubs as Lavender (tall and dwarf), Rosemary and the Southernwood family, *Artemisia*. The same remark applies, of course, to the smaller-growing *Yuccas*—*filamentosa*, *flaccida* and *angustifolia*—now often, and very effectively used in herbaceous borders.

Flowering plants with especially pleasing but low-growing foliage include *Heuchera*, *Rudbeckia maxima*, *Paradisca*, *Potentilla*, *Campanula persicifolia*, and *Pinks* and *Carnations*. All these, irrespective of the height of their flower stems, should be kept towards the front, when in some cases their upspringing blossom will serve to break the otherwise too even slope of vegetation.

SUMMER FLOWERS AT VINCENT SQUARE

ALTHOUGH the Show at Vincent Square on July 11 was not quite equal to those of late, there was a pleasant variety and the hall was fairly well filled. The few vacant spaces were apparently allotted to the National Carnation and Plectee Society, which held its Southern Section Show in conjunction with the R.H.S. meeting. Their

and to supply fuller particulars in view of a probable award. It has solid flesh and a small stone, and is of good flavour. Mr. G. P. Berry of the Ministry of Agriculture, who has a good opinion of its merits, says it is a prolific variety which promises to be profitable for market purposes.

The principal floral exhibits included very handsome stove and greenhouse plants, many

Roses were staged by Messrs. Paul, Frank Cant and Co., D. Prior and Son and the Rev. J. H. Pemberton, who all had excellent collections. The most popular Rose seemed to be the deliciously fragrant crimson Red Star, though the dusky maroon Dinah fascinated many visitors. Such golden and orange yellow sorts as Golden Emblem, Independence Day, Margaret Dickson Hamill and Rayon d'Or were also well shown.

NEW AND RARE PLANTS.

Begonia Sir J. Reid.—An exceedingly handsome double-flowered tuberous-rooted variety. The Camellia-like flowers are of perfect shape and bright orange colour, while the foliage is prettily marked, making it a most desirable variety. Award of merit to Messrs. Blackmore and Langdon.

Carnation Mary Murray.—Quite the best of the canary yellow Border Carnations. It is exceedingly vigorous, free-flowering, and the flower-stems are so stout and erect that supports are unnecessary. The flowers are large and slightly perfumed. First-class certificate of the National Carnation Society to Messrs. Lowe and Gibson.

Carnation Snowflake.—That this was the premier white self at the Carnation Show is an indication of its great excellence. The flowers are of medium size, well formed, and the habit and tohage are ideal. First-class certificate of the National Carnation Society to Mr. J. Douglas.

Clematis sp.—A very graceful free-growing species which bears long racemes of four-petalled star-like white flowers. The pea green glaucous foliage is reminiscent of *C. Armandi*, and it appears to be a very desirable species where a climber of free habit is needed. The award is subject to naming. Award of merit to the Rev. W. Wilks.

Eschscholtzia Crimson Carmine.—A welcome addition to the Californian Poppies. The varietal name aptly describes the colour of this exceedingly showy annual. The flower is made more conspicuous by having a white centre. *Eschscholtzias* are not generally known to be excellent for cutting. Award of merit to Mr. W. H. Gardiner.

Helenium Crimson Beauty.—This is a rather brighter *H. cupreum*, and should be a valued addition to the genus. Its height will make it useful for the middle and back portions of the flower border, and it should also be valuable for cut-flower purposes. Shewn by Messrs. G. Jackman and Son.

Hypericum sp.—The award to this valuable hardy shrub was subject to its being named. It may well be termed a buttercup yellow form of *H. patulum Henryi* and, like that variety, should be very useful for the front parts of the shrubbery. It is of good habit and very free flowering. Award of merit to Mr. Lionel de Rothschild.

Lilium gloriosum.—This is one of the many *Lilium pardalinum* hybrids raised by Mr. Amos Perry, and was the most robust of the many he had on view. Judging from the cut spike, we should expect the growing plant to become about 3ft. high, so it is of quite useful size. It bears plenty of blooms of pale orange colour, freely spotted with crimson. The floral segments are relatively long and pointed, so that it is a very graceful flower. Award of merit to Mr. Amos Perry.

Magnolia macrophylla.—This South-Eastern United States species bears the largest leaves of all the Magnolias. Under really suitable conditions they are said to become 3ft. in length, while those at the hall were about 2ft. long. They had rather a delicate appearance and were of thin

THE GRACEFUL NEW ROSE, KEW RAMBLER.

display was not so extensive as its promoters anticipated.

It was interesting to see, in only a few, some exhibits of fruits and vegetables in addition to the flowers. Messrs. Carter and Co. had some really good Peas and Broad Beans, both as whole plants to illustrate their bearing capabilities and as dishes of gathered pods. The Peas were two new dwarf sorts. Superb crossed with Quite Content gave Raynes Park No. 1 and Raynes Park No. 2. The former is said to be the earliest and to grow 1½ ft. in height, while No. 2 is a second-early and 2ft. in height. Both have pods as large as Carter's Quite Content. These very promising sorts are to be tried at Wisley, and we await the result with great interest. The Broad Beans were all of fine appearance, and included such sorts as Green Leviathan, Green Loupod, Mammoth Loupod and Mammoth Windsor, and all seemed equally valuable.

The fruits on show were a collection of Tasmanian-grown Apples of excellent appearance by Mr. Frank Walker and two varieties of Red Currant by Messrs. G. G. Whitelegg and Co. The Apples included Jonathan, Croton, Esma and Hoover of brilliant crimson colour and the delicate Dunn's Seedling. Messrs. Whitelegg's Currants were Orpington Prolific and Littlecott Beauty. Fruiting branches and gathered fruits of each were staged, and they illustrated exceedingly fruitful habits and large clusters. Like the Peas and Beans, these are to be tried at Wisley, after which, no doubt, they will receive awards.

A seedling black Cherry was submitted to the Fruit and Vegetable Committee, and Mr. Yates, the exhibitor, was asked to name the variety

Roses, Carnations, Lilliums, Delphiniums, garden Pinks and other border flowers. A very large exhibit of the old favourite Madonna Lily (*Lilium candidum*) was shewn by Messrs. Barr and Sons, pleasantly scenting the hall to a considerable distance, and many garden lovers who experience some difficulty in establishing this beautiful Lily were amazed at the quantity of handsome spikes. Besides that which received an award, Mr. Amos Perry shewed a number of his interesting hybrids of *Lilium pardalinum* and *L. regale*, which should prove valuable garden plants.

Some beautiful herbaceous Phloxes were shown by Mr. H. J. Jones. Messrs. Blackmore and Langdon had some stately Delphiniums and double Begonias of great merit. Lady Rhonda is a very handsome orange-coloured variety bearing intense nicely waved flowers.

Japanese Irises of great excellence were staged by Messrs. Whitelegg and Co., and Messrs. W. H. Rogers and Son. Messrs. Lidhams, Limited, had a long stretch of *Lavatera Olbia rosea*, which was particularly effective. Messrs. John Forbes, Limited, brought from Hawick in Scotland, Phloxes, Delphiniums and other border flowers. The alpines were not so numerous as of late, but these included the fascinating silvery lavender batch of *Campanula Bellardii* Miranda in a collection by Messrs. R. Tucker and Son. Mr. M. Pritchard had an interesting collection of good garden Pinks.

The Carnations were all excellent. Messrs. Allwood Brothers had many good sorts and also an abundance of their Allwoodii. Mr. C. Engelmann also had a fine display.

texture. They are oblong-ovate, pale green above and silvery grey beneath. The bloom was of correspondingly noble appearance, being quite 4ins. across and of globular shape. The dull creamy white petals are stout and fleshy, and there is a slight fragrance. It is a handsome tree for a sheltered spot, though, while hardy, is liable to injury from spring frosts when young. Cultural commendation to Mr. Lionel de Rothschild.

Phlox suffruticosa Snowdon.—This is quite the best white-flowered herbaceous Phlox we have seen. It is of sturdy habit and bears very large, compact trusses of pure white flowers, which are relieved from insipidity by the closely set cluster of deep primrose-coloured stamens. The flowers are pleasantly fragrant. Shewn by Mr. H. J. Jones.

Rhododendron auriculatum variety.—This appears to be an interesting white variety of the Chinese species which was introduced by Wilson in 1900 though it was discovered by Henry in W. Hupeh. The whiteness is in the flower-stalks as well as the blooms, and there are soft hairs on the stalks and towards the base of the exteriors of the flowers. Award of merit to the Hon. H. McLaren.

Rhododendron discolor, pink variety.—A pleasant soft pink variety of the beautiful fragrant, hardy Rhododendron which received a first-class certificate on June 27 last. Award of merit to the Hon. H. McLaren.

Rose Kew Rambler.—In general appearance this graceful, free-flowering Rose is a slightly smaller rose pink American Pillar, though the foliage is slightly glaucous. It was raised at

Kew by crossing the Chinese *R. Soulieana* with the popular *Hawatha*. It is of robust habit, the outer parts of the petals are of wild rose colour, and it is eminently adapted for planting on pergolas, archways and for similar purposes. Award of merit to the Director, Royal Gardens, Kew.

BORDER CARNATION CLASSES.

ALTHOUGH there were not many exhibitors at the annual show of the National Carnation and Picotee Society (Southern Section) on July 11 last, there were quite sufficient high-class blooms to enable visitors to see how beautiful and decorative the Border Carnations really are. The bizarres and flakes which in years gone by were the Alpha and Omega of the Carnation fancier, have almost entirely fallen from favour. It is a matter of congratulation to the Society that these formal yet attractive varieties were no longer shown on boards with a stiff paper collar around their necks. The present day method of exhibiting the varieties in vases permits them to be set up in a natural and graceful manner so that quite a number of visitors admired the six varieties which Mr. R. Morton, Woodside Park, shewed so well. His collection included an almost perfect bloom of Master Fred, which proved to be the premier bizarre bloom in the Show. He also had excellent blooms of Meteor and George Morland.

There were no white ground Picotees in the open classes, but Mr. James Douglas shewed such splendid blooms that he was awarded the remaining five first prizes. His very best blooms included the new Snowflake; Salmon Clove, a most

deliciously fragrant variety which was judged as the best clove-scented in the show; Marechal Niel, a self almost of the colour of the well known Rose that bears the same name; Viceroy, the best of the yellow ground Fancy Carnations; and Stereota, the premier white ground Fancy, while in the special class for clove-scented varieties his best was Scarlet Clove, a variety of vivid colour, almost as strongly scented as Salmon Clove, and King of Cloves, which in intense dark crimson colour and in fragrance approaches the old Clove Carnation.

There were ten or eleven classes of a rather more decorative character, inasmuch as buds were used in addition to the blooms and these, we imagine, were colour classes, but there was no indication on the exhibitors' cards or in the schedule as to their object or nature. None of the cards bore any other than the class number, so the general visitor received no assistance from them. Still, we suppose "the flowers are the thing" (to paraphrase), and in these classes they were all charming. Mr. Douglas earned out most of the first prizes and incidentally he again won the Cartwright Challenge Cup. Here his outstanding varieties were superb blooms of Cherry Blossom, Albion, King of Cloves, Scarlet Clove, Kelson, Eclipse, Prospero and Margaret Keep. Miss Elizabeth Shiffner, Lewes, won first prizes with very fine vases of Gray Douglas, Border Yellow and Effie Deans.

In the principal amateurs' classes Miss Shiffner was the most successful exhibitor, and she again won the Martin Smith Challenge Cup. Her splendid vases of blooms included Lieutenant Shackleton, Salmon Clove, White Fox, Border Yellow, Elizabeth Shiffner, Fujiyama, Gordon

PERHAPS THE BEST WHITE PHLOX, *P. SUFFRUTICOSA* SNOWDON.

THE MAGNIFICENT SOFT-YELLOW BORDER CARNATION MARECHAL NIEL.

Douglas, Mrs. R. P. Smith and Grey Douglas. Mr. J. J. Keen, Southampton, won first prize with Huntsman, which was also the premier scarlet flake; Gannymede, premier heavy-edged Picotee; and Eclipse, premier light-edged Picotee. Mr. Keen's were all splendid blooms.

In the amateurs' division for growers of fewer plants, Mr. E. W. Painter, Brentford, was particularly successful, and he won the Charrington Cup with very meritorious exhibits. The two classes for Carnations grown unprotected in the open border did not induce great competition, but the best three vases shown by Miss J. B. Wells, Clapham, were of high quality, as also

was the one vase shown by Mr. E. J. Lowe, Cricklewood.

Large non-competitive collections were arranged by Mr. James Douglas and Messrs. Lowe and Gibson, and these were so good as to receive medal awards from both societies. Mr. Douglas had excellent vases of Maroon Clove, Bookham Rose, Gordon Douglas, Fair Ellen and Lieutenant Shackleton. Messrs. Lowe and Gibson gave special prominence to their new Mary Murray, which received a deal of admiration. Among their collection were also the sweetly scented Surrey Clove, Kathie Moore, Skirmisher, Border Yellow and J. Saville.

THE WHITE BUTTERFLY PEST

The life-history of the offending species as it bears upon methods of control

OF course one finds White butterflies elsewhere as well, especially in the Cabbage fields, but they are essentially garden pests. The reason for this is not far to seek. When the caterpillars are full-fed they at once begin to seek out some dry, sheltered spot where they can pupate in safety and comfort; the spot must be dry and it must be sheltered. A garden, with its fences and wooden sheds, provides many more suitable places than an open field. Still, on the face of it, this hardly seems a sufficient reason, because the butterfly, though she takes care to lay her eggs on the food plant, certainly does not look so far ahead as to choose a place suitable for pupation. It is, however, a fact that both butterflies and moths have a tendency to hover and linger over the place where they emerged from the pupa case, and butterflies born in a vegetable garden will probably stay there. This is, naturally, particularly the case with the female insects.

This characteristic of the white butterfly suggests a remedy, and that is, the thorough sweeping out of all sheds and outhouses, where there will most surely be pupae. The pupae will be found at the end of July and all through August, and also during the winter. It is the July and August brood that is the more important of the two yearly broods; it is these insects that produce the great swarm of butterflies in May. Also, at this time we are not helped very greatly by the insect-eating birds; they have no young ones to feed, and there is plenty of food for themselves.

Among all the butterflies that come to our gardens there are only the large and the small whites that have injurious larvae. There is a little doubt about the caterpillars of the green-veined whites; it is possible they do some harm to the leaves of Turnips and Cabbages, but their natural food is Hedge garlic, Winter Cress and Watercress, and whatever harm they do is infinitesimal compared with that done by the other whites. Their larvae are very like those of the small whites, but the insects themselves are easily recognised, for their hind wings are yellow with very dark venings.

The large and small whites are too well known to need any description, though the differences between male and female may not be very common knowledge. In the case of the large whites, both have white wings, with black-tipped fore wings and a black spot on the hind wings; the female has two black spots also on the fore wings, while the male has only one. Both sexes in the small whites are very much alike, and neither has the spots very much black. Another difference is that the large whites generally lay their eggs on the underside of the leaves, while the small whites as often choose the upper.

The large whites are seen on the wing from May to August, but the small whites appear as early as April and are sometimes seen in November. In the appearance of their caterpillars they differ too. Those of the large whites are the most generally known, because they are much more evident than the others. The small, green larvae of the small whites are often hardly distinguishable from the leaves they feed on, but the blue-green bodies, the black tubercles, the three yellow lines running from head to tail, these make the larvae of the large whites very prominent creatures.

Both species feed for about a month before pupating, and both take about a week to hatch from the eggs, but the weather has a great deal to do with prolonging or lessening these periods. The eggs are very easily seen, almost as easily as the caterpillars, and hand picking of both eggs and caterpillars is the best remedy. There are others, but they injure the plant as well as the larvae. One of the least damaging is the scattering of lime and soot over the plants, but if this is done when the larvae are resting on the under surface of the leaves they will escape. On dull, dark days they will be found resting, and also at dusk; though it is quite possible that they may go on eating through the night. A sharp shower of rain often washes them off the leaves; therefore, a sharp spray of water from the hose pipe will do the same thing. The larvae of the large whites, especially, have a habit of rolling off the leaves when disturbed, but you have to be quick to collect them or they will find their way back to the plants.

When you see a white butterfly in the kitchen garden, follow it. Most probably it is a female, intent on egg-laying; the males prefer the flower garden. Anyway, a glance will tell you the sex, for the markings on the wings are very apparent as the insect flies. If you approach too closely, it will lay its eggs in ones and twos, but if you take care not to disturb it, the whole batch of from six to sixty will be laid in one place, and it is then a simple matter to destroy them. Incidentally, there is nothing more exquisite in the whole world of nature than these golden eggs of the white butterfly, with their twenty longitudinal ribs and finely chiselled transverse lines. They each have a little base, and, when the tiny larvae hatch out and eat their shells, these little white bases remain to show where the batch of eggs was laid. After the shells are eaten the larvae turn their attention to the leaf, but, until the second moult, they keep closely together; after that, they gradually scatter in all directions.

The caterpillars of the large whites have one single weapon of defence, a very curious one. They are able sometimes to eject from their mouths a drop of green, disagreeable smelling liquid. This

Fig. 1.—Eggs of the Large White butterfly (*Pieris brassicae*), greatly enlarged

Fig. 2.—The very young larvae of *P. brassicae* work in companies and are relatively easy to collect and to destroy.

Fig. 3.—Six caterpillars of the Large White species have reached maturity. One has already pupated, four have been attacked by *Ichneumon*s, and one, though not pupated, appears to have escaped attack. The grubs of the parasite are spinning cocoons beside the dead larvae. Such cocoons should on no account be damaged or destroyed.

Fig. 4.—Garden White butterflies: The Small White (*Pieris rapae*), the Large White (*P. brassicae*), female and male.

is, however, all that they can do; it may perhaps protect them from the attacks of birds. Sparrows eat them in spite of it, but most other birds will not touch them, except when they are very small and then probably they are collected for the nestlings.

It is a depressing but interesting reflection that for an immense number of years—ever since man first started the cultivation of the wild sea Cabbage—agriculturists all over Europe, in Northern Africa and in some parts of Japan, have been trying to exterminate the white butterfly, and have never really had the least permanent success. Perhaps if the balance of nature had not been so recklessly interfered with the butterflies might not have increased so disastrously, in spite of our having supplied them with unlimited quantities of the food they prefer; sparrows, if they had been allowed to do so, would certainly have accounted for a very great number, and the little black ichneumon fly, *Apanteles glomeratus*, that is such an inveterate parasite of the larvæ, would have done more good still if its cocoons had not been systematically destroyed and the fly itself killed by the sprays that were meant to kill the caterpillars.

There are country folk still who call the cocoons of these ichneumon flies "caterpillars' eggs" and crush them as soon as found! It is impossible to say what might have been the position to-day if the sparrows and the ichneumons had had a free hand; but ignorance and stupidity have fatally checked them. The extent of the small parasite's operations among the cabbage caterpillars may be estimated by the fact that, out of a hundred larvæ collected, more than half will

generally be found to have been "stung" by the ichneumon. They are, of course, not really stung at all; the fly has laid her eggs in the butterfly's eggs or in the larvæ—probably in the eggs, in spite of reiterated assertions to the contrary—and the grubs, hatching out, have fed on the larval juices and eventually killed the larvæ. The grubs, at this stage of their existence, when they have destroyed their host, are ready to pupate. Each step in their career, from the laying of the eggs to the death of the caterpillar, has been for their benefit and for their host's destruction. All the scenes in the really dreadful little drama are played out with unerring precision. When the grubs are ready to pupate, so is the caterpillar—if it could. All it can manage to do, however, is to spin its little pad of white silk on which, as a normal chrysalis, it ought eventually to have been suspended, but which the grubs immediately annex. While the silken pad is being spun they have sucked a little opening in the skin of the caterpillar and now come tumbling out, each in a tremendous hurry to get safely inside its cocoon. These cocoons are piled up anyhow on the silken pad, close to the empty and used-up caterpillar, and owing to their size and golden yellow colour they are very conspicuous little objects.

Nothing that we can do, no remedy that we can possibly devise, will destroy the cabbage caterpillars so effectually as the "sting" of this ichneumon fly, and the greatest care should be taken that neither the fly nor its cocoons are injured by insecticides and sprays, and especially that the cocoons are not destroyed through ignorance.

M. H. CRAWFORD.

possibly causing the loss of the bloom through damping as the flower nears full development. Three days after the buds have been "taken"

"TAKING" THE BUDS.

DISBUDDING LARGE-FLOWERED CHRYSANTHEMUMS

TO cultivators it will not seem to be a long time since the cuttings were inserted, as the days go by quickly to those deeply interested in their work. That interest will now be still deeper, as the very interesting phase of cultivation has come, namely, the "taking" of the flower-buds. Of course I am referring to the selection of buds on plants grown to bear large blooms of those of the Japanese section and blooms refined and of high-class quality of the incurved and single-flowered sections respectively.

Beginners and those of limited experience are generally somewhat puzzled as to how they should treat their plants at that stage when the flower-buds form, as they will do from the middle of July till late in September, according to the variety and season.

Varieties which naturally flower late, if propagated late in winter-time, will not, if grown naturally, show buds till late in August or early September. Such buds would be too late to develop into large blooms. We will, however, suppose that all propagation and "stopping" of shoots has been done in due time and everything is quite in order; the flower-buds will then appear on, or near to, the right date. The massive blooms of the newer varieties require a long time in which to develop from the bud stage. It may be—as was the case last year—that some buds will be shewing by the date these words are in print. All such of late sorts must be gradually "taken," as to remove such buds and then depend upon later ones would spell disappointment in the shape of thin blooms shewing an eye.

Some of the largest blooms grown in this country last year were the result of "taking" buds on

July 15; they were late-flowering sorts. The blooms are larger from crown buds than from terminal; the latter, it is true, produce flowers richer and deeper in colour, but usually lacking in depth.

HOW TO "TAKE" THE BUDS.

In the accompanying sketches the crown bud is shewn at *a*, the side shoots *b*, *b*, and *c*, *c* must be gradually removed when they are less than 1 in. long; not all in one day, but one or two each day till only the bud and the main leaves are left. The letter *d* shews the bud growing freely, and *e* shews how buds with weak stems may be supported and kept in an upright position. Watch the buds day by day, and go round the plants at night and inspect them by lantern light. Earwigs are fond of the buds, and will soon do a lot of harm if not checked. They eat out the centres as shown at *f*. While the flowers are in the bud stage it seems a trifling matter enough, but see, at *g*, what the result is as the bud develops; the flower petals are packed very closely together in the bud, and in one night the earwig will spoil the bloom as shown at *g*. There are, besides the earwigs, small grubs that gnaw the tender stems just below the buds as shewn at *h*. Result: half the bud fails to develop, as shewn at *i*, the other half, *j*, being affected too, in sympathy it would seem to be. To prevent damage to the tender stems the cultivator should dip fingers and thumb in soot and gently smear a small quantity on the stems.

Aphides, of course, must be kept off the plants. Should they infest the buds, syringe them off with clear water early in the day. Do not use tobacco powder on the buds, as some will remain and eventually work down among the petals,

recommence the judicious feeding of the plants as before.

The main requirement of the *Chrysanthemum* cultivator, indeed of gardeners in general, is a capacity for taking pains. GEORGE GARNER.

THE SOUTH SEA MYRTLES

THE *Leptospermum*s are much hardier than is generally supposed. Though they attain their greatest perfection on the South Coast, they can be grown satisfactorily and without the shelter of a wall in all but our bleakest counties. They appear, however, to need a well drained loam, and if there is any doubt as to their being able to stand the winter, a mound of ashes at the base will generally save the plant should the upper parts get cut back by frost. One of the most beautiful is *L. Nicolli*, with velvety crimson flowers, and it is doubtless as easily managed as the commoner *L. bullatum* (*scoparium*). *L. Boscaweni*, the white flowers of which are suffused and centred with crimson, is a very lovely form, coming near to *L. Chapmanii* in appearance, and *L. stellatum* is a good creamy white. They are evergreens of an erect, slender habit with tiny, rather bronzed leaves.

CORRESPONDENCE

IRIS NOMENCLATURE.

OUR attention has been drawn to a letter appearing in your issue of July 8 over the signature "Geo. Dillistone," criticising our action in giving the supplementary name "Sunset" to M. Denis' beautiful Iris *Ochracea cœrulea*.

We think it is desirable to state that Mr. George Dillistone is a member—we believe a director—of the firm of R. Wallace and Co., Limited, of Tunbridge Wells. A few of your readers may be aware of this, but the majority probably are not, and we draw attention to the fact because we will not be drawn into a controversy with a trade competitor in the columns of the amateur gardening press; it would be neither interesting nor edifying to your readers.

We wish to say that those of your readers who are interested in this matter will, we think, be quite satisfied with the manner in which we have dealt with Iris *Ochracea cœrulea* in our Iris catalogue if they will be good enough to refer to this publication.

We must also add that, so far as we are aware, this Iris has never been offered to the public in any Iris catalogue hitherto published in this country, on the Continent, or in America, and that if we should have stated at any time that we are distributing it this season, we should have been perfectly justified in doing so. Further, the name "Sunset" has not previously been appropriated for any other variety in any Iris catalogue with which we are familiar, nor does it appear in the American Iris Society's List of Irises (at any rate, not in our copy), as stated by Mr. Dillistone, and we have every right to use it as a supplementary name. Our reasons for doing so are sufficiently obvious and well founded.

We have never willingly misled our customers with regard to any matter in connection with the plants we sell, and we are not doing so in this case.—G. G. WHITELEGG & Co.

THE SYRINGA.

I WAS under the impression that the word *Syringa* applied to the Lilac only. In Bentham's *Flora* there is a reference to "*Philadelphus* (*Syringas*)" under the family of Saxifrage, and to Lilac (*Syringa*) under the Olive family. Again in *THE GARDEN* of July 1, "Pruning and Thinning Flowering Trees," page 313, mention is made of "*Syringa* (*Philadelphus*)," and *Syringas* and Lilacs are separately named. Would it not be correct to classify *Syringa*=Lilac, *Philadelphus*=Mock Orange?—W. T. D.

[The botanic name of the Lilac is *Syringa*, and the common name of the *Philadelphus* is Mock Orange or *Syringa*, though the latter is unquestionably more generally used, which is unfortunate. It certainly is wiser always to refer to the *Philadelphus* as Mock Orange.—ED.]

ROSE "GERBE ROSE."

THE different futures of the two women in the Gospel narrative who were grinding corn is but one instance out of an immense number where it is inexplicable why one should be taken and the other left. What has Gerbe Rose done that it is not more frequently seen clothing pillars or rambling over arches in our kitchen gardens when others of no greater decorative merit are here, there and everywhere? Is it that it cannot be labelled with that delightful Irishism, invariably associated in my own mind with a great raiser who is a very St. Chrysostom in his descriptions of new Roses? If it falls short of being "very perpetual" it is *proxime accessit*. It has splendid vigour. It is a cut-and-come-again in the multitude of its blooms. I do not know whose nose

a Rose has to satisfy before it is admitted into the select circle of Selection 12 in the 1921 Rose book of the National Society; but again it must be *proxime accessit*. It is described in that invaluable little publication as "deep pink." That is just what it is. I want to pass on something of the enthusiasm of a rose-lover who has lately made it known to me. She even coupled it with *Zéphirine Drouhin*. One hopes that history will repeat itself in the case of Gerbe Rose and that, like *Zéphirine*, it will in the end come into its own.—MAELOR.

THE SPIRIT OF THE GARDEN.

A summer's day was sinking to its close.
Hushed was the busy hum of Nature's life
With all its myriad voices and around
The well known daylight colours of the flowers
Changed all their values in the mellow light.
Peace reigned. On every hand the garden lay
In that sweet state, half sleeping, half awake
Where the soul's ocean breaks on conscious shores
Waking those utterances which men call dreams.
This mood the poet knew and well perceived
The Spirit of the Garden brooding near;
Yet, as he mused, the question crossed his mind:
"Where are thy haunts and when may'st thou be found?"

Unspoken was the thought, unspoken too
The answer, borne upon the evening air.

"When in Spring life wakens slowly
Making earth rejoice
In the soft air blowing lowly
Breathes my voice.

"Where the moonbeams bright are falling
On the dew-starred grass
And the nightingales are calling
Do I pass.

"Summer's sun which bids the flowers
Glow with fragrant light
Traces on the dial the hours
Of my delight.

"When life fades, the funeral pyres
Flame from shrub and tree
With the antman-coloured fires
Lit by me.

"Where the hoar-frost glistens brightly
O'er the frozen land,
He who loves a garden rightly,
Sees my hand.

"Noble park or plot most humble
Both are haunts of mine
For alike I fill a temple
Or a shrine.

"Gardens all, whatever their measure,
Filled with loving care
Hold the source of highest pleasure,
I am there."

A. E. SIMS.

THE SUMMER ROSE SHOW.

THE Show is getting back to its pre-war size, but all those wonderful groups, wholly or in part made up of plants in pots, were still conspicuous by their absence. Have they, I wonder, gone for ever?

The groups had gone, but Miss Willmott told me that she thought it was the finest Show the Society had ever had. Now, of all people Miss Willmott knows what's what in Roses. Another

testimony to its excellence was that of Mr. E. H. Woodall. He, too, is no mean authority. What struck me more than anything was the almost universal break away from the ancient jammed-all-together arrangement of the flowers in the groups. I am sure the poor Roses appreciated being given breathing room; and I am still more sure that all who came to see them thought the change beneficial.

The weakness of the Show appeared to me to be the slovenly way in which many of the round baskets were finished off. There has to be a behind-the-scenes, one knows, but one does not want to see it. Probably moss, like early sown vegetables, has not grown over well this dry spring, but surely enough could have been found to hide the wire and tubes necessary to hold the flowers in their places.

Managers of larger shows than the Rose Show would do well to take notice of the spacious gangways. It makes the whole difference to the enjoyment and comfort of the visitors; and, what is of equal importance, it helps trade. Now trade at a show is like charity in daily life, it blesses the visitor no less than the exhibitor.

No one who has ever been to a National Rose Show if asked to name its most distinctive feature could make any other reply than "The new Roses tent." The long thick line of patient waiters outside the entrance would not have disgraced the outside of a theatre when a popular play is running. Then once inside all was order. It was refreshing after the higgledy-piggledy, shoved-in-anyhow flower salad behind the iron bars at Chelsea!

The popularity of the Decorated Table section is as great as ever. There were in all no fewer than thirty-four tables competing in one class or another. Unfortunately the beauty of the arrangement of the whole is not the one and only thing to be thought of—probably because of this I profoundly disagreed with most of the awards of the judges. If the arrangers of the flowers had to grow their own, there might possibly be something to be said for show standards being necessary in the individual blooms, but when all the flowers and all the foliage may be acquired by purchase or by presentation it is rough on the exhibitor who has no friend at court or who has not a very deep purse; and yet can arrange simply and tastefully. The table that was, to me, miles ahead of all in the tent only got a "third" in its class. Is it easier to make a silk purse out of a sow's ear or out of a silken skein?

Lastly no one could fail to notice a general improvement in the look of the Botanic Gardens themselves. Now, more than ever, they make an ideal home for a show. The Rose Show is a very wise creature.—JOSEPH JACOB.

BORDER CARNATIONS.

I NOTICED a letter from my friend Allwood in a recent copy of your paper, and although the copy is lying on my desk at Edenside half a mile away, perhaps you will allow me to reply to the only important point I noticed that, to my mind, needed elucidating. The whole sense of Mr. Allwood's letter seemed to point to some potent gift of perpetuity possessed by hybrid Carnations as opposed to the flowering period of the genuine Border strain. Nothing could be more illusory nor calculated to puff one section against another (quite innocently, I admit, for we all acquit Mr. Allwood of any such unfair intention). I suppose the full flowering period of a Carnation in the garden is from June to September, inclusive. The gardener who cannot produce Border Carnation bloom over that period has something to learn. Almost every variety of our new Clove-scented Borders, if grown the second and third year in the same place without disturbance, will produce bloom from May until September, and even October if the weather is dry.

I seem to have heard that "a shoemaker's wife is usually badly served for shoes." Surely in the same sense the wife of a Carnation specialist is usually badly off for Carnations. At any rate, I am about to confess that in my garden there is only one Carnation plant. (I must have Lavender, Sweet Williams, Pansies, Stocks and Roses—but Carnations, No, sir!) This plant of the new Bookham-White Clove, planted October, 1920, has been in bloom (rarely having less than three blooms on at the time) since May 21 last, and I herewith give you an account of its present development as I stand before it: 128 layers, or growths, for 1923 flowers; fifteen visible flower spikes that will bloom between end of July and end of September; ninety shoots bearing buds that will flower within the present month; sixteen shoots bearing full blooms and buds shewing colour, some of them 4ins. across, the calyx of every one perfect, and the scent of the flowers perfuming the evening air with the glorious aromatic Clove odour.

In spite of the heavy winds of the last week all spikes are standing erect without staking,

the appointment, should go thoroughly into the objects the Wisley Gardens are intended to serve. Perhaps to some extent this has been done since I see in *THE GARDEN* that the genus *Crocus* is to be grown and compared, a very welcome change, in my opinion, from the eternal trials of vegetables and flowers. I consider the value of these trials to be immensely over-rated since they determine only the best varieties for a light sandy soil and climatic conditions similar to those obtaining at Wisley.—SUSSEX.

THE MOCK ORANGE.

YOUR beautiful picture of *Philadelphus Coupe d'Argent* in the issue of July 8, page 332, has moved me to write on behalf of that now unfashionable shrub *P. grandiflorus*, which, flowering later than most of the Mock Oranges, is large flowered, pure white and noteworthy for its graceful habit and vigour. It attains a height of 15ft. to 20ft., which adds greatly to its value in many situations. It is, of course, scentless, but not everyone will consider this a drawback. For cut flower purposes it is certainly a great advantage

SWEET PEAS AT EASTBOURNE

SELDOME, if ever, have such fine Sweet Peas been seen as at Devonshire Park on July 12 and 13, when the National Society held its annual show there on the invitation of the Eastbourne Horticultural Society. The great Winter Garden was filled with glorious, fragrant spikes of large blooms, and there was an enormous attendance.

The principal interest was centred in the trade competition for the Eastbourne Challenge Cup, presented by the county borough and valued at 60 guineas. Each of the many competitors was allowed a space 15ft. by 4ft. 6ins., and there were no restrictions as to varieties or style of arrangement. The judges experienced considerable difficulty in awarding the first prize, as the magnificent exhibits by Messrs. Andrew Ireland and Hitchcock and Messrs. Dobbie and Co. were of such even merit that only a half point separated them. However, the greatly desired trophy was finally awarded to Messrs. Dobbie and Co., who had a magnificent lot of Sweet Peas, all of high quality, but lacking the bright colours of their closest competitors. Among the many sorts shown by Messrs. Dobbie and Co. were Dignity, Royal Scot, Melba, Renown, Constance Hinton, Pink Pearl, Tangerine Improved and Jean Ireland.

In the superb effort by Messrs. Ireland and Hitchcock vivid colour was displayed by the generous vases of such as Hawmark Pink and Tangerine Improved, while Daisybud, Jean Ireland and Elegance were also exceedingly charming. The gold medal awarded for this collection was richly deserved.

Messrs. Sutton and Sons had perhaps the most attractive style of arrangement in all these gigantic displays, but, though of first-class quality, their blooms were not quite equal to the super-excellence of the two former exhibits.

Messrs. Sutton's gold medal exhibit included Picture, Tangerine Improved, May Unwin and Hawmark Pink.

Silver-gilt medals were awarded to Mr. J. Stevenson, Messrs. S. Bide and Sons, Mr. W. J. Unwin and the Preston Hall Nurseries, while Messrs. Carter and Co., A. Jewell and P. W. Abbott received silver medals for collections which on ordinary occasions would have been considered of great excellence, but this was no ordinary occasion.

The Monro Challenge Cup was for competition among the trade growers, and it required twelve vases of varieties raised or introduced by the exhibitor. With the trophy goes the Society's gold medal, and this valuable first prize was decisively won by Messrs. Ireland and Hitchcock, who had exceptionally meritorious vases of such as Mrs. A. Hitchcock, Olive, New White and glowing blooms of Tangerine Improved. Messrs. E. W. King and Co., who were second, had superb spikes of Giant Attraction, Anglian Orange and Mrs. A. Hitchcock.

Messrs. King and Co. won the Burpee Challenge Cup with a charming arrangement of excellent blooms of waved varieties, and they also had, in Rosemary (shades of pink), the best vase of seedling Sweet Pea.

The raser's class was won by Mr. J. Stevenson, and his very best varieties were Fair Lady (deep blush pink), Crimson Glow and Wild Rose; the colours of the two last are well described in their names.

With superb spikes of Mascott's Helio, Picture, Mrs. A. Hitchcock and other sorts Mr. L. Horton won the E. W. King Cup, offered for the best twelve varieties on sale during the present season.

PHILADELPHUS GRANDIFLORUS. PROOF OF OUR CORRESPONDENT'S CONTENTION.

and these characteristics we claim for thirty-five out of our forty new Cloves and for 80 per cent. of our listed Border Carnations if the plants are grown the second and third year without disturbance. For many years we have carefully selected for hybridisation varieties that have shown a tendency to "Perpetual" habit, until now we claim that our strain, if treated as already mentioned, will flower over the whole of the period permitted by our changeable climate.

I do not desire to animadvert on the rest of my friend's letter, but only to sympathise with him on the lack of taste shown by the important societies he mentions in not fathering his bantlings. That is strange also, for I never knew the Royal Horticultural Society backward in acknowledging merit, or the National Carnation Society for that matter.—JAMES DOUGLAS, *Great Bookham*.

WISLEY GARDENS.

I HAVE not heard of any successor being appointed to the late Mr. S. T. Wright, Superintendent of Wisley Gardens, so imagine that the Council are taking their time in the hope of finding the man best suited for the post. I would respectfully suggest that the Council, when considering

as the scent of the otherwise valuable *P. coronarius* is quite overpowering indoors.

Philadelphus Lemoinei and its derivatives are admittedly very useful for the front of the shrubbery, but there has been of late years a tendency to plant them, even in large gardens, to the exclusion of the plant of which I enclose a picture. This should not be.—H. H.

PRUNING CLEMATISES.

IN your issue of December 31 last you publish a letter from Mr. Owen Thomas in which he tells us how to train and prune the Clematis *Nellie Moser* so as to get 1,500 fully expanded flowers out at once. I think he is mistaken in ascribing *Nellie Moser* to the Jackmanni section instead of the Lamignose section, an inaccuracy that is misleading, as the two sections require very different treatment. He says that in January, 1920, he had all the shoots cut back to within 9ins. of the ground. I imagine the result would be that in that year he got no blossom, or very little, as *Nellie Moser* blossoms on the old wood.—E. L. W.

[Mr. A. G. Jackson, a recognised authority, advocates precisely the same pruning for the Lamignose and Jackmanni sections.—ED.]

PLANTS FOR A SMALL MORAINÉ GARDEN

(Continued from page 322.)

The President's Prize is in open competition, and Mr. A. H. Parsons, Lewes, won the cup, medal and money prize with a really great exhibit. His spikes of Renown, Mrs. A. Hitchcock and Matchless were the very best. The best varieties not yet in commerce were shown by Messrs. S. Bide and Son, who included Almas Beauty and, in Nancy and Unique, two uncommon bicolors.

The Sutton Cup, open to competition among amateurs only, evoked extensive competition, and was won by Sir Randolph Baker, whose best sorts were Picture, Felton's Cream, Jean Ireland and Mrs. A. Hitchcock. The same competitor had the best amateur display of Sweet Peas, and this was highly decorative. The highest quality amateur blooms were in the *Daily Mail* Cup class, which was won by Mr. F. W. Franks, Loampits, Tunbridge, with a superb collection, including, in the vase of Picture, the best vase in the competitive classes. The best vase of a novelty Sweet Pea was that of Mascotte's lugman, a rich rosy cerise, in the second prize set of Mr. H. Walker, Lewes, which was of such excellence that the judges must have experienced great difficulty in awarding the prizes. Chief among the other sorts in these superb collections were Jean Ireland, Valentine, Matchless, Elegance, Royal Purple, Royal Scot and Mrs. George Shawyer, though all really deserved mention. Mr. Franks also won the Edward Webb and Son's Cup and a number of first prizes in the colour classes.

At the Show the best varieties of the different colours were Constance Hinton (white), Hawlmark Pink, Orchid (lavender), Dobbie's Cream, Fiery Cross (orange scarlet), Royal Scot (cerise), Field Marshal (crimson), Warrior (maroon), Jean Ireland (picotee-edged) and Mrs. Tom Jones (blue). The blooms in the smaller amateurs' and local classes were also of very gratifying quality and were greatly admired.

Large space had to be devoted to the decorative classes, and most of the exhibits were very artistic. Mrs. A. D. Ruff, Shornbrook, had the best dinner-table decorations and won both first prizes. Her association of orange and pale blush shades and mauve and blush with elegant foliage was particularly successful, as also was Mrs. A. R. Bide's basket of Sweet Peas. A large table of beautiful stands of Sweet Peas and splendid dishes of fruit in great variety arranged by Mr. C. R. Aust of Eastbourne was one of the features of the show.

In tents on the lawn there were many delightful miscellaneous exhibits by the trade. Messrs. Allwood Brothers won the Silver Challenge Cup and piece of plate with one of their superb collections of Carnations and Allwood's Pinks. Mr. C. Scaplehorn almost filled a smaller marquee with a wide range of excellent border flowers, a Lily pool and bank of Ferns. Messrs. J. Cheal and Sons had a good collection of many types of Dahlias, Roses and border flowers.

Many fine spikes of Eremuri of such as E. Bungei and E. Shelfordi were associated with various hardy border flowers by Messrs. G. Bunyard and Co. A beautiful miscellaneous exhibit was made by Mr. G. I. Scott, who seems to be able to grow *Gilia coronopifolia* very easily, as he had many excellent plants. Hardy flowers were also shown by Messrs. Maxwell and Beale and Messrs. G. and A. Clark; while Messrs. Carter and Co. had splendid Begonias, Gloxinias and Eschscholtzias arranged with Sweet Peas.

Very many Carnations, largely of the sorts valued for market purposes, were well set up by Mr. C. Engelmann, and adjoining these Messrs. A. and J. McBean had a large collection of valuable Orchids.

LEONTOPODIUM ALPINUM.—The Edelweiss being quite happy in other parts, it is not necessary to find a place for it on the moraine, although I suppose space should perhaps be found for some of the recently introduced Chinese "lemon-scented" representatives of this genus.

Linaria alpina.—Lovely as this miniature "Snapdragon" is, owing to its seeding itself so freely it became a nuisance to other less vigorous plants and had to be weeded out altogether. There is always plenty of it in other situations away from the moraine, both the blue and the prettier rosy variety.

Lithospermum Gastonii was only once tried, and I failed to establish it. It seems a difficult plant to move and if taken from a pot should be planted without the ball of earth being disturbed, which one probably forgets at the time. It was flourishing in several parts of a very beautiful rock garden in a Yorkshire dale in the limestone region visited by me in 1918, the plants being nearer 2 ins. high than 4 ins., the height given in the list. It hardly seems to be a suitable plant for moraine even if it could be successfully established.

Mertensia primuloides—an exceedingly pretty Himalayan Borage with velvety, blue-purple, kaleidoscopic coloured flowers—flourishes, but the flowers are invariably aborted, owing to the frosts that nearly always occur when it is coming into flower; this is due to the moraine being fully exposed to the early morning sun, which, shining on to them after a night's frost, has a deadly effect. It should be quite satisfactory in a more sheltered position.

Myosotis rupicola.—Tried, but not very satisfactory. Very difficult to keep, and must be treated, as with other "Forget-me-nots," at the most as short-lived. Of course, the happy thing would be for it to sow and maintain itself, as do the commoner representatives of the family.

Morisia hypogea.—Finely flowered plants of this dwarf, evergreen-leaved, yellow-flowered plant are quite desiderata. It usually does well in moraine, the only danger being that, its stems becoming "woody," it has a tendency to rot off in very damp winters, although seedlings spring up round the parent plant at times.

Papaver alpinum.—The lovehest of "Poppies," which maintains itself happily for a longer period in moraine, and, as it seeds itself freely, there is usually no fear of losing it. Quite indispensable, both for its beautiful flowers and pretty glaucous foliage and for the lengthy period it keeps flowering if prevented from seeding. If allowed to seed freely it may take advantage of conditions which it fully appreciates and take up more space than is desirable.

Petrocallis pyrenaica.—Have had no difficulty with this member of the *Draba* family, with its close green cushions covered in the spring with squat pink flowers. It keeps quite compact in moraine (in richer soil it tends to become "leggy") and does not require winter protection. My plant has been in its present position seven or eight years, and, although it has increased in size, its growth has been very slow.

Polemonium confertum mellitum.—One is somewhat in a difficulty here as to what plant was really meant; this difficulty is also intensified when the plant under this name is ordered from some of the dealers in alpine. There seem to be so many inferior *Polemoniums* about, passing under good names, that one may have many disappointments

before the right plant is obtained. I do not seem to have succeeded yet, although one of the first plants received as this proved to be quite a good dwarf species with very pretty pale blue flowers on short stems; the foliage was very squat, and the plant seemed quite at home in the moraine, but never seemed to increase much, and, owing to being moved, was eventually lost. It was possibly *P. lanatum*, and it is a plant that I should like again. Other plants that I have had have produced nothing satisfactory, and *P. confertum* is still a desideratum. I find that Mr. Farrer evidently changed his mind as to *P. confertum* mellitum, as he writes at a later date that *P. confertum* is "far preferable to its variety *P. c. mellitum* which is so much commoner in gardens."

Primula × intermedia.—This hybrid could not very well be tried unless it had been obtained from Mr. Farrer's own nursery, as it does not seem to appear in lists and it is probably difficult to differentiate in a class in which there are countless numbers of hybrids.

P. spectabilis.—I tried this *Primula* more than once, but failed to maintain it for more than one or two seasons. *Primulas* have not been a success with me on the moraine, the family requiring something more substantial in the way of soil than is usually provided in the gritty moraine. If any of them do show signs of succeeding they soon seem to be attacked by pests such as *Noctua larva* or Crane fly ("Daddy Long legs") larva, which lay round about underground and gnaw through the stem at about the ground level, and you usually do not realise what is happening until it is too late.

The type of *Primula* that seems to be most satisfactory is *P. viscosa*, the very striking hybrid *P. Mrs. J. H. Wilson*, and other *P. × pubescens* hybrids, if only good forms are retained. A citron yellow flowered one that I have is a pleasant contrast to the brighter almost magenta coloured *P. Mrs. J. H. Wilson* near by. The plant referred to in 1917 as *P. leuteola* and sent me as such proved to be *Cortusa Matthioli*, a totally different plant, with pretty foliage quite pleasantly scented, and crimson, white-eyed, pendent flowers; it requires richer soil and does better away from moraine. *P. Wulfeniana*, *P. carniolica*, *P. × Venzoi* and *P. Allioni* were also tried, but without success.

Ranunculus alpestris.—This lovely flowered white "Buttercup" maintained itself for some time in the loamy part of the moraine, but only flowered very sparingly, and trying to better its condition only ended in my losing it altogether. It is now being tried away from the moraine, but owing to the very dry spring following last year's exceptionally hot summer it has not flowered. The leaves are being attacked by a leaf miner and also by the caterpillars of one of the smaller moths.

R. glacialis, is usually found very high up in the Alps and is quite common in places at the foot of the higher glaciers, in positions saturated with water trickling down from the same—conditions difficult to produce in a "waterless" town garden. It has had two trials, but never got into the second summer. The last that was tried had a place specially made for it, and was saturated with water in the early spring through free drainage. It commenced to grow, but it proved impossible to keep the slugs off it, and it never had the slightest chance of ever getting into leaf.

R. parnassifolius, although slow in establishing itself, really was the best of those tried, and

Catterly flowered very well on fairly short stems, not drawn up as is the case with plants put in the shade. The plants kept dwarf and increased nicely until last summer's extra dry spell, which threw them back so much that they were moved to a more sheltered and I hoped more suitable position, but they have failed to flower this year, as have

also the larger *R. amplexicaulis* and *R. grandifolia*.

R. Seguieri.—This Dolomite version of *R. glacialis* included in the list and stated to be easier and freer, has not been tried, it rarely being included in plant lists.

(To be continued)

A BEAUTIFUL WILD ROSE

The Musk Rose in the Temperate House at Kew this season was worth going far to see.

THE accompanying illustration directs attention to the decorative character of one of the most beautiful of the wild

Roses—*Rosa moschata*, the Musk Rose of Southern Europe, Asia Minor, Northern India and China. It is a climbing plant which, in a natural state, ascends to the tops of trees 50ft. or 60ft. high, throwing out as it climbs long rambling branches, which in their right season become festoons of large, white, fragrant flowers. As is to be expected with such a widely distributed plant there is a good deal of variation in habit and size of flowers between specimens collected in different countries and there is a marked difference in hardiness. The two most distinct forms in cultivation are marked by green and glaucous-green leaves, the latter being less hardy and a distinctly inferior plant to the former. The form with plain green leaves grows at least 30ft. high in Southern England and several fine specimens are to be seen in the Rose Garden at Kew, one being particularly well placed at the foot of a large Holly. The branches have reached the top of the Holly and the flowers are seen to great advantage against the dark background. As may be seen from the

THE MUSK ROSE, ROSA MOSCHATA

illustration the flowers are produced in clusters, the clusters often measuring from 1ins. to 1½ins. across and the individual flowers from 1½ins. to 2½ins. in diameter. When first they open the petals are creamy white, changing soon after to pure white, the central mass of stamens being golden in colour. The accompanying photograph is of a plant raised from seeds received at Kew under another name from India. Its hardiness being doubtful, it was planted in the west porch of the Temperate House. The position suited it admirably and it grew very freely. In 1921 it blossomed well, but evidently the sunny summer of last year ripened the wood better than usual and it has been a magnificent sight this year, flowering more freely

than it has done on previous occasions, the clusters of blossoms being specially fine. Plants that have grown out of doors for many years are also flowering

better than usual, which proves the accuracy of suggestions that have been made from time to time regarding this species, *i.e.*, that the best results can only be expected by a thorough ripening of the wood. During wet summers numerous very long, strong shoots are formed, but they almost invariably suffer severely during winter. If planted in good loamy soil in a position where the branches are fully exposed to sun, *R. moschata* may be expected to thrive and it cannot fail to please the most fastidious of Rose lovers. There is a variety with double flowers, but it is no improvement on the type. *R. moschata* may be found in some gardens under the name of *R. Brunoni*, a name given by Lindley to the Musk Rose. W. D.

GARDENING OF THE WEEK

FOR SOUTHERN GARDENS.

The Kitchen Garden.

Spinach.—Seed to produce plants which will yield pickings during the autumn and winter may be sown from now onwards at intervals according to requirements until the latter part of September. The drills should be spaced about 15ins. apart and the plants left about 4ins. or 6ins. from each other. Should the weather be dry at the time of sowing, the drills should be well watered previous to scattering the seeds. The prickly type is the most reliable for these sowings, but should these have failed on some soils to give sufficient returns, a sowing should also be made of the Spinach Beet or Perpetual variety, from which an abundance of leaves may always be gathered during the spring.

Autumn Onions should be pulled up as their foliage ripens and laid in the sun to complete ripening before being stored away in cool quarters. In the event of the weather being showery, the bulbs should be laid on trellis-work to keep them from the ground.

Globe Artichokes.—Where this vegetable is appreciated and the plants are growing on porous soil it will be necessary to give a few waterings to aid in the development of the heads. All heads should be cut as soon as ready for use, otherwise they become tough. Stored in water in a cool place this vegetable will remain in good condition for some time.

The Flower Garden.

Hedges.—Any necessary trimming of Yew, Box or Thorn may be done now. Where close or formal effect is required a pair of garden shears must be used, but where this is not desired a pair of secateurs or a strong knife should be employed.

Helianthemums, or Sun Roses as they are more popularly called, are useful for dry edgings, as well as for the rockery and walls. There are two forms, the single and the double. The former may be raised from seed, while the latter must be increased by cuttings. Both may be propagated now, using a light sandy soil and a cold frame. Where a quantity of Sun Roses are established on a large, dry bank some of the seed may be scattered about as soon as it ripens, and quite a measure of success should be obtained in increase of plants.

The Hardy Fruit Garden.

Summer Pruning.—This work having been completed on wall trees it may, where thought necessary, be commenced on Apples, Pears, Plums, etc., growing in the open, whether trained in pyramid, standard or bush form. There is, I think, a tendency to carry out this operation too early—sometimes, with the evil result that a lot of secondary growths are encouraged from buds which should have remained dormant and, indeed, would have done so had pruning not been done so early. It is somewhat difficult to lay down any definite rules, as so much depends upon the development of each tree. A general rule is to shorten side growths, leaving from five to eight leaves, while leaders and growths required for extension may be left full length or only slightly shortened according to circumstances.

Fruit Under Glass.

Pot Trees of Peaches and Nectarines having been cleared of their fruits must be removed to the open. It is still most essential that the trees do not suffer from lack of moisture at the roots, and until such time as the wood is well matured the feeding of the trees must be kept up. This may be discontinued when the leaves begin to come off. Care must be taken that strong winds do not blow the trees over, and unless stout stakes are made use of to combat this it is better partly to plunge the pots in old ashes or on a spare plot of ground.

Pot Vines grown with the object in view of fruiting next season must be kept well supplied with nourishment and receive all the light available, as it is most important that the wood become hard and thoroughly ripened. Suppress all unnecessary lateral growths and concentrate every ounce of the plants' energies into the building up and proper maturation of firm wood and plump, well ripened buds.

H. TURNER

(Gardener to the Duke of Northumberland),
Albury Park Gardens, Guildford.

FOR NORTHERN GARDENS.

The Kitchen Garden.

Shallots.—Ripe Shallots should now be pulled and laid in a sunny position so that they may be thoroughly dried before storing.

Autumn-Sown Onions may also be lifted immediately they are ripe. After a thorough drying in the sun they should be removed to a cool, airy loft or shed.

Curly Kale.—Fill up a goodly portion of the ground that has been cleared of early Potatoes with some of the dwarf-growing varieties of Kale. These winter greens are always in favour, and although late in the season for general planting, nice useful heads may be depended upon for winter use if planted now. Plant fairly close in lines 18 ins. apart.

Leeks.—Complete the planting of the desired quantity as soon as possible so that they may develop into useful and well blanched specimens before the winter months. Leeks are gross feeders, so that the ground should receive generous treatment by being heavily manured.

Fruit Under Glass.

Melons in Frames.—Where the fruits are swelling they may be considerably assisted by the application of a top-dressing composed of old turf with a liberal sprinkling of old lime rubble and artificial manure. Elevate the fruits on pieces of slate placed on an inverted flower-pot, so that they may be kept clean and clear of the foliage. Keep all lateral growths in check. Syringe and close the frames as early in the afternoon as possible. Late batches coming into flower should be fertilised daily until the required number are set.

Late Crops of Figs.—Trees in late houses should have all the air it is possible to give them, and should be syringed daily to keep the foliage fresh and clean. In well drained borders abundant supplies of water will be required and the roots should be fed according to the crop the trees are carrying.

The Hardy Fruit Garden.

Late Peaches and Nectarines.—Where red spider, aphids or other insect pests are in evidence, measures should at once be taken to combat them by spraying with a reliable insecticide. Spraying with clear water in the evening is also of much benefit in promoting a free growth of both wood and foliage. See that the border is kept in a moist condition, using liquid manure where it is thought advisable.

The Flower Garden.

Herbaceous Borders.—Plants in herbaceous borders now require considerable attention both in the way of staking and tying and frequent hoeing of the surface soil so that weeds may be kept in check.

Seedlings. Run the hoe between rows of the various seedlings growing in nursery beds and see that the young plants do not suffer from lack of water.

Border Carnations.—Keep the beds well hoed and give occasional waterings with liquid manure or soot water. This not only strengthens the flower spikes, but helps materially in producing fine strong growths for layering later on.

JAMES McGRAN

(Gardener to Sir Henry H. Houldsworth, Bart.),
Coodham, Kilmarnock.

GREENHOUSE AND CONSERVATORY.

Calceolaria violacea. This beautiful plant is hardy on warm walls in Devon and Cornwall, but is also fine for the cool conservatory, either planted out in a bed or border. It also succeeds well in 10 in. or 12 in. pots. Propagation may be carried out now by means of cuttings of the young shoots, using the shorter twiggy growths for the purpose. It is by no means an easy plant to propagate, and such shoots are more likely to root than soft gross growths. The cuttings are best rooted in a close case in a cool house. The plants grow quite well in ordinary light potting compost. Plants propagated at this time and potted on as they require it, should make nice specimens for the conservatory stage next year. This plant will flower with greater freedom in its second year when grown on as a large specimen.

Clethra arborea (Lily of the Valley Tree)—The small tree is a native of Madiera, and is particularly useful for planting out in a large conservatory; it also makes fine specimens when grown in tubs. There is a variety with variegated

leaves of pale yellow and rose colour which also makes fine specimens and grows as freely as the green-leaved form. These plants are easily propagated at any time by means of half-ripened shoots about 4 ins. long. The cuttings should be put in a close case in a cool house. They will grow freely in any ordinary potting compost, and if potted on as they require it soon make large specimens.

Senecios.—There are several species of Senecio which are well worth growing for the conservatory. *S. grandifolius* and *S. Petasites* are both useful for their large handsome foliage; the former being fine for planting out in a large conservatory. *S. Petasites*, grown in 6 in. or 7 in. pots, makes good plants suitable for the conservatory stage; while grown on in 10 in. or 12 in. pots it makes very handsome specimens for standing on the ground. Both species may be propagated at this time by means of cuttings, which root readily in a close case with slight bottom heat at command.

Senecio glastifolius is of quite a different type, having thin narrow foliage. It is a beautiful flowering plant for the conservatory and it produces rosy-purple flowers in great profusion. It may be raised from seed, which it generally ripens freely, or from cuttings, which may be rooted in a close case in a cool house at this time. If propagated at this time large specimens should be obtained for flowering next spring. Being a thin, slender-growing plant, it is a good plan to put three plants in a pot, if their final potting is into 5 in. pots; they should make fine specimens for standing on the ground. They require stopping several times to induce a bushy habit. If plants are required for the stage they should be rooted a month later, and should be confined to smaller pots.

Amphicome Emodi is a beautiful plant for the cool greenhouse which produces erect rose coloured flowers with an orange-yellow throat; the foliage is also very graceful. This plant may be propagated either by seeds or cuttings. The cuttings root readily in pots of sandy soil, placed under a bell glass in a cool house. The plants thrive quite well in a light rich potting compost. *A. arguta*, although not so showy as the former species, is well worth growing for the cool greenhouse. In warm, dry situations this species, if given some protection during winter, is fairly hardy.

Helichrysum humilis (syn. *Aphelaxis*), of which there are several varieties, were at one time great favourites for the greenhouse and as specimen plants for exhibition. At present they are seldom seen except in a few trade establishments, where they are grown in a small state chiefly for market work. They are "everlasting" flowers and retain their beauty for a long time. This plant may be propagated by means of cuttings at this time. Use for this purpose small side shoots. When taking cuttings, use a very sharp knife as the stems are covered with a woolly felt-like substance and unless great care is used in trimming off the leaves, the bark is stripped off and there is little chance of their rooting. The cuttings should be inserted in pots containing fine sandy peat. Well water the cuttings with a fine rosed can and stand under a propagating glass in a cool greenhouse. When rooted pot the young plants into thumb pots, using fine sandy peat for this purpose. In subsequent pottings the peat should be of a rougher character, while a little charcoal may with advantage be added. The pots should be well drained and great care in watering must be exercised at all times, as these plants are very impatient of stagnant water at their roots.

Phænocoma prolifera is another beautiful plant producing "everlasting" flowers; even if it never flowered it is worth growing for its fine, grey coloured foliage and stems. Well matured plants attain a height of some 3 ft. This plant is propagated and grown in the same way as the *Helichrysum*, but even greater care is required in preparing the cuttings, the stems also being covered with a felt-like substance. J. COLLIS.

Royal Botanic Gardens, Kew.

British Bulbs. The Secretary of the Royal Horticultural Society informs us that there will not be a Bulb Show this year, but exhibits of home-grown bulbs will be welcomed on August 6 and 22. Applications for space should be made in the ordinary way a week before the meetings and be accompanied by a declaration that the whole of the produce shown has been grown in the British Isles.

ANSWERS
TO CORRESPONDENTS

FRUIT GARDEN.

PEAR TREE NOT FRUITING (An Old Reader).—The variety may be one that requires the pollen of a free setter to be fruitful. Furthermore, root pruning in November would be beneficial. Very severe branch pruning without dealing with the roots at the same time (year) would result in a still more robust branch growth. Water thoroughly in dry weather and apply a substantial mulch. The immediate treatment should be summer pruning in July. Cut back the current year's shoots to five or six leaves from the base. More young shoots will grow at the end of the shoot or cut-back branch in each case, and these must be rubbed out while quite small. In due time the ordinary winter pruning should be done. When root-pruning take out a trench semi-circular in form and 4 ft. to 5 ft. from the stem of the tree. Cut off all large roots crossing the open trench, then fill the latter with a gritty compost and fibrous loam, and make it all quite firm.

CHERRY TREE ATTACKED (A. S. W., Carnarvon).—The insect attacking our correspondent's Cherry tree is one of the Ermine moths (*Hyponomeuta* Sp.). The caterpillars are nearly fully fed and will shortly pupate in the nests on the tree or about the trunk, and the moths will appear about a fortnight later. These adults will then proceed to lay eggs in masses on the small twigs of the tree. The egg masses are covered over with a glutinous substance which protects the eggs and, later, the young caterpillars, which hatch in the autumn and remain under the glutinous substance during the winter. In spring the minute larvae leave their shelter and enter the expanding buds, where they penetrate the tissue and feed. In May they reappear in the open and spin up the nests or tents, which can be easily seen on infested trees. As regards treatment in the case of a single tree being attacked, it is advisable to cut out the nests with long-handled pruners and burn them. In case some caterpillars have escaped and pupated singly and the adults have laid eggs on the twigs, a lime sulphur spray should be applied at the rate of 1 in 10 in spring, about a fortnight before the buds show signs of movement—say, the first week in March.

PEARS ATTACKED (S. W.).—From careful examination of the fruit sent it would appear that our correspondent's tree has been severely attacked by the Pear midge (*Diplosis pyricornis*, Riley). This pest is a small midge which lays its eggs in the blossom. The minute maggots feed on the developing fruitlets, in many cases causing the total failure of the crop. The maggots leave the damaged fruitlets in early June and fall to the ground, where they burrow into the soil and change into pupae, which remain below ground until the following April when the flies emerge. Very little can be done as regards controlling the pest. In the cases under notice the condition of the fruitlets examined indicates that the maggots left some time ago, so that little can now be done. Good results have followed an application of Kainit to the soil beneath the trees at the end of May. The best plan would be to burn the soil under the trees to a depth of about 6 ins. This is a very laborious operation, but is the only one likely to yield satisfactory results.

MISCELLANEOUS.

DESTRUCTOR FOR BURNING GARDEN REFUSE (C. B. R.).—We do not know of any destructor of the kind described by our correspondent and advise him to write to Messrs. Osman and Co., 132-134, Commercial Street, London, E., and state his requirements. If unable to obtain the right kind of destructor, one may be made as follows; it is simple, answers the purpose and is very cheap, also durable. Procure seventy-five ordinary hard-baked bricks, make a hole in the ground 1 ft. deep and 2 ft. across, then build up a loop-holed wall round the hole in the ground about 18 ins. high. This is an ideal destructor, in which all kinds of rubbish may be burned or charred to ashes. If the wind is strong put on an iron lid; if calm, burn the rubbish without the lid on. The holes in the wall should be about 2 ins. wide, about six of them in each course, or layer, of bricks. Everything will be consumed and the ashes will be available as manure for the garden.

NAMES OF PLANTS.—N. G. W.—1, *Calycanthus floridus*, "Carolina Allspice"; 2, The Rose had fallen to pieces on arrival.—M. L.—1, *Campanula trachelium*; 2, *Cistus albus*; 3, The Rose had fallen to pieces on arrival.—M. W., Renfrewshire.—*Spiraea Menziesii*. This is a shrub (not a climber) which attains a height of 3 ft. to 5 ft. *Spiræas* thrive best in good loamy soil. Abundant moisture and full sunlight are essential.—"Wish-low."—*Arum Draconculum*.—J. B., Surrey.—*Arum Draconculum* (common Dragon).

BARR'S Beautiful New Seedling NERINES

The most beautiful and easiest grown of Autumn-flowering Bulbs for the Greenhouse.

Bulbs now ready for potting to flower in the Greenhouse this Autumn.

For autumn decoration in the greenhouse few plants can compare with Nerines for their brilliant and attractive colours. The flowers, which are produced in umbels of 6 to 24 blooms, are borne on stout stems varying in height from 1 to 2 feet. In colour they range from *dark red, vivid crimson, cerise and scarlet to salmon, coral-rose, pink, blush and white*, many having a glistening lustre which in sunlight gives them the appearance of being dusted with gold or silver. They remain decorative for many weeks, and their beauty may be enjoyed in a sitting-room as well as the greenhouse, if the pots are kept in a sunny window.

THE WILD GARDEN AND ITS PLANTING

AS this is one of the seasons when the wild garden is especially attractive, it may not be inapposite to consider its arrangement and planting. The wild garden of to-day has little in common with the "wildernesses" of times gone by and is, indeed, essentially modern in feeling. Like the "Yorkshire moor" style of rock garden, it is especially suited to those whose taste inclines to the realistic in Art. A well designed wild garden will nowhere betray the Art that fashioned it unless it be that the prodigality of perhaps alien vegetation calls its natural origin into question.

The plants which may be used in wild gardening are many. It is the more regrettable, therefore, to find plants there which by their habit of growth or cultural requirements are unsuitable. The ideal wild garden, like the chameleon, changes in appearance according to environment. On the light soils of Surrey it will probably be woodland in character, and Rhododendrons, Heaths, Azaleas and Kalmias will be largely in evidence, also Scotch Firs and Silver Birches. Little grass cutting will, in this case, be called for.

On richer, alluvial soils shrubby and herbaceous Spiræas will luxuriate in company with Gunneras, Heracleums and other plants largely valuable for ample foliage. In moorland districts the native Heaths may often be reinforced with other species and varieties to improve the effect. Water or natural bog in the wild garden-to-be can always be turned to good account.

Because a particular plant does well in, let us say, a Warwickshire wild garden it by no means follows that it will succeed equally well or form a satisfactory part of the picture in a Surrey one. Much outlay both on plants and labour has been wasted in establishing particular families of

plants in uncongenial surroundings only to provide effects which were not entirely happy, when a tittle of the outlay would have produced results satisfactory in every way. The plants mentioned below must, therefore, be considered only with reference to suitable environment.

Natural effects are not always beautiful, and if our wild garden is to be a success forethought must be used in the planting so that we may obtain as many satisfactory well balanced pictures as may be, not just at one season, but the greater part of the year. A certain amount of contouring is almost invariably desirable. It should assist in giving dignity to the weightier masses and should also please by its own unaided beauty of

"hillside" occasionally to get the necessary glimpses.

FOR WOODLAND WILD.

Semi-shade in woodland is, of course, the natural home of most Rhododendron species. It certainly suits the hardy hybrids admirably also, yet the average hybrid Rhododendron seems hardly suitable for the wild garden, and the same may be said of many of the species, which are often rather gaunt and unattractive when out of flower. The old Rhododendron ponticum, of which fine bushes are often to be found in woodland—it is an excellent covert plant—is admirable for the woodland wild, where its

purplish flower trusses tone admirably with the violet shadows. The common yellow fragrant Ghent Azalea is much at home in such a situation, and if it grows a little "loose-jointed," few will quarrel with it on that account. It will be found that the Japanese Maples will succeed here too. Dampish ground suggesting a little spring will accommodate the Sweet Pepper, Clethra alnifolia, the Royal Fern, Osmunda regalis, or that best of all the Meadowsweets, the brilliant rose red Spiræa palmata. Bamboos may be included where the effect desired is somewhat exotic and it biting winds are not prevalent. How effective these may be in woodland the wild garden at Wisley bears witness. In association with these

A TYPICAL WILD-GARDEN SCENE.

curve. Naturally, ways must be left through which to walk and admire the plants. These will resolve themselves into tramped paths or "sheep-tracks" in semi-woodland or quite informal grassy vistas on open ground. It will be more effective if these traverse the valleys made in contouring unless a general view is desirable, in which case the path may climb the

we may well plant many species of Lily, such as L.L. giganteum, auratum, speciosum, pardalinum, Henryi, regale and testaceum. This last again associates well with the Clary-like purple Wood Sage, Salvia virgata.

Over-thick planting is fatal in the wild garden, especially if in woodland, for space should be left effectively to display not only

HARDY GHENT AZALEAS IN THE WILD.

JAPANESE ANEMONES

the larger plants already referred to, but lowlier plants, such as Primroses, Cowslips, Oxslips, Violets, hardy Cyclamens and such bulbous things as Bluebells, Snakes-heads (*Fritillaria*), Dog's Tooth Violets (*Erythronium*), including some of the beautiful American species and varieties, *Triteleas*, etc. If space and growing timber permit, such beautiful trees as Birches, some of the Willows with coloured bark (*Salix daphnoides* and *S. vitellina*, for example) may be planted.

THE OPEN WILD GARDEN.

An open grassy glade with moderately good soil will accommodate such plants as *Heracleums* of sorts, such *Rheums* as *tanguticum*, *Gunneras*, the brilliant Willow Herb which transfigures some of our railway banks, *Epilobium angustifolium*, the purple Loosestrife, *Lythrum Salicaria* (of which the rosy forms are best), such *Berberises* as *stenophylla* and *Darwini* (keep clear of weeds until established), Brambles and Rose species of sorts, New Zealand Flax, *Phormium tenax* (not in colder localities), such Cranes' Bills as *Geranium Wallichianum* and *G. atlanticum*, Day Lilies (*Hemerocallis*) in variety, many hardy Orchises—but their special requirements as to lime or what not must have attention—and Lilies such as *croceum* and *tigrinum*. The more upright-growing *Cotoneasters*, such as *C.C. Simonsii*, *acutifolia*, *pinnosa*, *Francheti*, *frigida*, etc., Japanese Cherries, and such flowering Apples as *Pyrus floribunda*, *P.P. Schenckeri* and *Niedzwetzkyana* will furnish the knolls, and in partial shade at their feet, even though the soil be on the light side, Primroses, whether wild, coloured or blue, will flourish. If the soil be really good and they be kept free from coarse grass, the single and double Japanese Irises, *I.I. setosa* and *laevigata* (*Iris Kraemeri*) will make a brave patch of colour in their season.

By waterside or in bogland the Siberian Irises and their cousins, the varieties of *Iris orientalis*, will luxuriate, with yellow and bronze *Mimuluses* and water-loving *Primulas*—*P.P. japonica*, *Bulleynana*, *pulverulenta*, *Beesiana*, *helodoxa*, *sikkimensis*, *chionantha*, *Parrvi*, *Poissoni*, *latifolia* and *rosea*. Indeed, in ground naturally fairly moist and in partial shade most of these plants will do well quite away from water, as will the herbaceous *Spiraeas*—*S.S. palmata*, *gigantea elegantissima* and *g. rosea*, and *Ulmaria flore pleno*—and *Astilbes*. The Goat's Beard, *Spiraea Aruncus*, does not require a specially moist spot, and with its handsome foliage and towering creamy plumes is a splendid wild garden plant. The cut-leaved variety *S. A. Kneith* is less strong growing and not recommendable for the wild though valuable in the herbaceous border.

In shady corners the bulbous plants mentioned as suitable for woodland will succeed, while in more open spaces drifts of *Crocuses* and *Daffodils* will be gorgeous in their season and again in autumn the *Colchicums* will add beauty and colour. It is needless here to particularise suitable *Daffodils* for this purpose; suffice it to say that the best of all is that stately Pheasant's Eye, *Narcissus Poeticus recurvus*.

Other plants there are which will be successful or not according to the particular soils. If Brooms flourish in the neighbourhood, they should certainly be made a prominent feature of the wild garden. The same will apply to those beautiful flowers the Mallows, which often flourish in the same localities. Lupins, both the Tree Lupin, *Lupinus arboreus*, and the herbaceous forms of *L. polyphyllus* will succeed in any moderately light soil. Of many flowers which seem much out of place in the wild garden the garden Phlox may be taken as an "awful example." *Delphinium* and *Anchusa* are awkward plants which cannot truly be naturalised, but they have not the gauche, unhappy look that distinguishes the Phloxes in such planting.

Autumn colour and "berry" effects are well worthy of consideration in the wild garden. Rose species, the taller *Berberises*, the before-mentioned *Cotoneasters* and their relatives the Thorns (*Crataegus*) will first spring to mind in the latter connexion, but the combined foliage and fruit effects of two native shrubs, the Guelder Rose (*Viburnum Opulus*), and the Waytaring Tree (*V. Lantana*), should give them a high place in any list of desirable species.

COLOURED FREESIAS

A Flowery Mede—Cultivation—Seedling Raising.

YOU know the ladders at election times with either the candidates or the parties climbing up them day by day. Were such ladders displayed in the windows of our big bulb dealers I have a shrewd idea that coloured Freesias would be found to be getting on very nicely in the race for popular approval. It is but a straw; but I know of one large firm whose list, which has hitherto been immune, will this autumn be found to be infected with named varieties. This new race of flowers is catching on. If only the public could have seen "flowery mede" in my "No. 6" greenhouse

pots of Dainty, Merry Widow, Apogee, Buttercup, Conquest or La Charmante. The mede may come after. The foundation stone of success is early potting. The sooner the bulbs are snug in their pots after August 15 is passed the better. Any good light soil suits them. It is a mistake to overpot them. Seven bulbs may safely be put in a 5in. pot and so on in proportion. They should start life in a cold frame or in a cold greenhouse, and have all the air possible, provided they are kept from cold draughts and protected against frost. No heat will be necessary until November, when the first batch may be given

sufficient stimulus to accomplish the purpose in life for which we grow them. There seems to be a work-shy strain in several South African bulbous-plants, in Freesias among others, so give them any decent excuse arising from any mistake or neglect and they will remain lazily and unconcerned in the soil for a whole year just as they were before when planted. Thus, on no account must pots after being in a comfortable greenhouse be suddenly put out into a cold frame to get on as best they can; provision must somehow be made for the annual baking before their contents are once more turned out as planting-time gets near.

Timely tying and staking add much to their appearance. Allwood's wire rings are good. At the Rose Show in June I was told that a special Freesia stick was soon coming on the market, and the inventor promised to send me some for

A BEAUTIFUL GROUP OF FREESIAS.

in the early part of March, 1920, the process would have been accelerated. It is one of the floral sights that comes back to me again and again. Familiar as I had been for a long time with the different varieties, I had never before realised what a big jumble-up of them altogether was like. There were whites, primroses, yellows, red mauves, blue mauves, lavenders, with here and there real pinks, soft oranges, bright roses and tawny reds. It was so different from the barbaric splendour of the Tulips, or the rich magnificence of the Roses, or the varied grandeur of the Dahlias. It was the simple quiet profusion of the ancient mediæval garden living again in my greenhouse, and had the Three Fates or Vertumnus and Pomona suddenly stepped down from their tapestries at South Kensington or Madrid ("L'Art des Jardins," by G. Riât) and appeared among the Freesias it would not have surprised me. Please make some allowance for the uncontrolled thoughts of an enthusiast. Take them *cum grano salis*; but just try a few

warmer quarters. We no longer attempt to get the coloured varieties into flower as early in the year as the whites. They do not seem to like the unnatural treatment, and they are apt to go blind and bring blooms which are a good deal out of character. Coloured Freesias do not need the softening influence of heat. Their colours are not improved, as is the case with such Tulips as Le Notre and Sweet Lavender.

Feeding with alternations of soot-water, some reliable fertiliser dissolved according to instructions in water, and very weak cow or hen beer begins when we see signs of the flower-spikes shewing through the leaves. During the actual period of flowering none is given—only pure water—but afterwards we start again and continue until the foliage shews evident signs of dying down, when both pure water and stimulants are gradually withheld. The after-care of the bulbs is most important. The coloured varieties seem extra sensitive to sudden chills, and they need a thorough good baking during May and June to give them a

trial. None has come so far. I must jog his memory. There is, of course, the old-fashioned way of caging the plants by putting there or four sticks round a pot and connecting them with raffia or twine at two or three levels as growth proceeds.

Freesias can be so readily raised from seed that a few words on this subject may be acceptable. I always sow as early in August as possible. The difference was most marked between those sown on August 6 and those sown on September 6 when they were harvested in the second week of this month (July). Pots—preferably the 6in. size—are used in preference to pans, as the bulbs are more easily dealt with when they are turned out, it being *most* important to keep the different little lots from being mixed with one another so that each stock may start life true. In sowing it is quite worth while to place the seeds in regular order, each one half an inch from its neighbour. This tends to help matters at turning-out time. Short, bushy little twigs 6ins. to 8ins. high should be stuck among the seedlings when they have

grown 2 ins. or 3 ins. No other staking is necessary. No stimulants are given until the new year has come in, and then only in a very weak form. During the winter months they are kept in the warmest of our cool houses, where the night temperature is between 40° and 45°. About March a few odd flowers may be expected, but we usually pinch them off when the first one has opened. At potting-time each main bulb *with its offsets* is put into a 5 in. or 3½ in. pot. These are amply large enough for producing good blooms and, later on, fine bulbs.

I have dwelt on seedling raising because it is so interesting. Seed may now be had from some dealers, and should be bought at once; but I would far rather get enough bulbs of good varieties to make a few potfuls so that one can have one's own seed. Cross-fertilisation is necessary to get a good set. Carrying out this operation and watching the results is most fascinating, and in the case of Freesias there is no long wait of years as in the case of Daffodils and Tulips. With good culture and management eighteen or nineteen months suffice.

JOSEPH JACOB.

ANTIRRHINUMS FROM SEED

DURING the sixties and seventies of the last century, florists prided themselves on improving the Antirrhinum. Popular varieties in those days were spotted or striped or both, much like the Carnations of the florist. Of twelve of the best named varieties, two were shaded, one a delicate rose self, and all the rest striped or spotted. These named varieties were popular exhibition flowers, and there was much emulation as to who should win the leading prizes. This fashion soon died out, but it still persists to some extent in the North and named striped varieties are yet offered by

some of the Scottish florists, though they now have a list of bedding varieties. Tall, intermediate and Tom Thumb strains existed in those days, and cultivators could grow bushes measuring 7 ft. by 5 ft.

MODERN IMPROVEMENTS.

The more recent improvements have been to get beautiful and bright self colours, or an attractive combination of two or more colours, giving good general effect when looked at from a short distance. All three sections continue to be improved in these respects, but the intermediate strain is the most popular, most numerous in varieties, and most useful. Many beautiful self colours now come fairly true from seed, or practically dependable as to colour, where the seed beds or cultures have been properly rogued. One is tempted sometimes to save one's own seed, but this inevitably leads to disaster in all gardens where two or more varieties are grown within easy distance of another. Antirrhinums are very popular with humble bees, which have no difficulty in opening and entering the dragon mouthed flowers, and cross them hopelessly for garden purposes. On first thoughts one might consider the resulting seedlings as reversions, but after a little reflection and on observing the bees at work, no one need hesitate as to the true cause of the mixing of colours in stem, leaf and flower.

TIME TO SOW.

Antirrhinums are sown at various times and under a variety of conditions, but the best time is undoubtedly in August or early in September, either in a cold frame, or a cool greenhouse. This gives the plants time to acquire strength under cool conditions, and if pinched once or twice the seedlings will make bushy specimens by the time they are planted out at the beginning of April. The Antirrhinum is a hardy perennial when grown in well drained, firm and not too rich soil, but it gives by far the best results, in longer spikes and larger flowers, if treated as a biennial, by being sown at the time indicated and wintered in a cold frame or cool greenhouse. Drip or damp is the worst enemy of Antirrhinums, and for that reason they should be reared and kept under drip-proof glass structures during winter and well ventilated except when it is actually freezing.

Good plants may, it is true, be raised from sowings made in January or February, germinating the seeds in a fairly brisk heat, but afterwards ventilating more or less freely according to the weather and keeping the plants exposed to all available light near the glass. Very good results may be obtained by this method, but the plants have not the same time to get strong and allow for pinching as when sown in August.

PREPARATIONS FOR SOWING.

When Antirrhinums are to be raised in any quantity it is best to sow them in boxes, either in lines or broadcast, the former being the most

convenient where numerous varieties in moderate quantity have to be reared. The boxes should be well drained with crocks all over the bottom, which should have slits or holes to let the superfluous

A TYPICAL LARGE-FLOWERED SNAPDRAGON.

water drain away. After putting some half decayed leaves or siftings of soil over the drainage, the compost should be filled in, pressed until fairly firm and made level, within a quarter of an inch or a little more of the top. Any light sandy soil, with some leaf soil in it will answer the purpose. It should be sifted to take out the lumps and other rubbish. The watering of seed boxes is always an important operation, and can be done by watering them heavily twice with a fine rose on the can, thoroughly to wet the whole of the soil. If there is any doubt about this, a sure plan is to submerge the boxes half their depth in a tub of water and leave them there till the moisture has risen to the top.

SOWING AND AFTER TREATMENT.

Whether the seeds are to be sown in lines or broadcast, it is always good policy to sow thinly, to promote a short-jointed sturdy habit, so that if they cannot be transplanted as soon as ready, no great harm will result if they have to wait a week longer. The seeds are small and this conduces to thick sowing, which should be avoided. Cover the seeds with a thin layer of the same compost and water that down with a fine rose. Place the boxes on ashes in a cold frame and keep the lights closed till the seeds are well up, when top air should be given. Should the weather be dry and bright, in order to prevent the soil in the boxes from getting dry it may be necessary to resort to shading. It is desirable to avoid watering as long as possible till the seeds have germinated, when the ventilation of the frame will make it necessary in dry, bright weather. Considering their internal structure and the stores of food surrounding the embryo, the seeds do not take long to germinate and after that event the seedlings grow rapidly. Hence a good reason for sowing thinly and for giving free ventilation to prevent them from getting drawn.

As soon as they can readily be handled they should be potted off singly in long thumb pots, transplanted into other boxes, 2 ins. apart each way, or directly into a cold frame on a prepared

THE BEAUTIFUL CLEAR-PINK INTERMEDIATE VARIETY NELROSE.

Best for winter flowering.

bed. About 3ins. or 4ins. of sandy soil and leaf mould laid over a level bed and pressed firm will answer the purpose. Dibble them into this in lines 3ins. apart and 2ins. between the plants at least. Give a good watering to settle the soil and keep the frame close for a day or two. Shading may or may not be necessary till the seedlings pick

up, when increasing ventilation should be given. Antirrhinums are liable to get mildew if kept unduly close for any length of time. With this exception they are not much subject to disease. They are, indeed, of easy culture, if their requirements as to light and air are well attended to all through the winter. J. F.

DWARF POLYANTHA ROSES

For the decoration of house and garden.

THE dwarf Polyantas, or as they are more familiarly called, the "Poly-Poms," originated from a cross between a Tea Rose and Polyantha simplex. In the Rose Annual for 1916 Mr. Walter Easlea, writing on this class, states that the first variety was Paquerette, which appeared in 1875; and though others followed, I think the two varieties which first made their way into many rose gardens were Cecile Brunner, 1880, and Perle d'Or, 1884. These have perfect little flowers of shell pink and apricot yellow respectively, and are exceedingly pretty if allowed to grow into good sized bushes; but if pruned hard they are apt to put up rather ungainly and leggy sprays, and are therefore not particularly suitable for bedding.

Now it is as bedding plants that these Poly-Poms are most valuable; therefore the advent of Mrs. W. H. Cutbush in 1900 was a very real gain to our rose gardens, and in spite of the beauty and brilliancy of many of the later varieties, I think it is true to say that Mrs. W. H. Cutbush still holds her place as the most popular of the

dwarf Polyantas. It has practically all the qualities useful in this class of Rose, a dwarf habit, good foliage, small flowers in good sized clusters of a particularly bright clear pink, which are freely and continuously produced and which stand a reasonable amount of rain without being spoilt. The only good quality in which it is entirely lacking is that of fragrance, and in this respect Ellen Poulsen (1912), with prettily shaped blossoms of cherry rose colour turning to soft pink, is superior to Mrs. Cutbush. Under glass Ellen Poulsen is quite first class, the flowers coming of a brighter and clearer colour than they do out of doors, and it is a favourite for cutting and bringing into the house; indeed, for all purposes for which a really dwarf variety is required Ellen Poulsen is hard to beat.

The Orleans Rose (1909) is more vigorous than the two last varieties and comes into flower a little later. It makes extra large sprays of deep rosy pink flowers and is very useful for cutting and putting into fairly tall vases. A charming little rose of a pale pink shade is Perle Orleanaise. This is one of the dwarfiest in habit, though Coronet,

with flowers of deep salmon flushed with pink, makes a good companion for it. The new Coral Cluster, if it proves to be as good in the garden as it is under glass, is sure to become very popular, for its soft salmon tints are very attractive and would be charming used for table decorations by artificial light. Jubana is another pale salmon coloured variety which is well worth a trial.

For some time Jessie, with bright cherry crimson flowers, was the best of the red Polyantha, but in the last few years several good reds have been brought out. Triomphe d'Orleanaise, bright carmine, large trusses; Koster's Orleans, a deeper coloured and less vigorous Orleans; and Verdun, similar to Koster's Orleans, but not so clear in colour, are three good varieties—if I eliminated one it would be Verdun. The best red in this type is undoubtedly Edith Cavell; the blossoms are really bright dark crimson, changing with age, not to dull pink or bluish red, but to blackish crimson. It is of the same habit and height as Koster's Orleans. A very dwarf and brilliant crimson variety, well named Eblouissant, is, on account of its extra dwarf habit and freedom of flowering the most useful of the reds as an edging to beds of taller Roses. It is in some respects more like a China than a Polyantha; the colour is very much that of the old Craunoisic Supérieure.

Katharine Zeimet is an excellent very free blooming white Polyantha. It comes early into flower. Yvonne Rabier is another good white; it is, however, prettier when allowed to grow into a good sized bush than when pruned hard. It has a delicious fragrance. Anne Marie de Mont-ravel is a dainty, very dwarf variety, with unusually well shaped little blossoms. Little Meg, a cross between a white Hybrid Tea and Shower of Gold, is a great favourite of mine. It has glistening

APTLY NAMED, POLYANTHA ROSE CORAL CLUSTER.

THE NEW GLORY OF HURST BIDS FAIR TO SUPERSEDE ORLEANS ROSE.

dark foliage, apparently quite mildew proof, and pretty white buds tipped with red which open to pure white flowers of a fair size and shape. It is very perpetual and has a charming effect when cut for arranging in small baskets or vases; it lasts a long time in water.

I know of no really satisfactory yellow Pompon. George Elger is the best; it is free flowering, and the buds are a good yellow, but they open to rather an uninteresting pale shade. We want a yellow of the brilliant colouring of Mrs. Wemyss Quin or Christine.

We have found the most satisfactory way of growing these dwarf Polyanthas is in small round

beds on the lawn—about a dozen plants in the bed. We prune them very hard towards the end of March. Like all Roses, they require a good deep rich soil to start with, and a certain amount of liquid manure during the summer adds to their vigour. If I were limited to growing half a dozen for bedding my choice would be: Mrs. Cutbush, Orleans and Ellen Poulsen, pink and rose; Edith Cavell and Koster's Orleans, crimson; and Katharine Zeimet, white.

For edging other rose beds, Eblouissant (crimson), Anne Marie de Montravail (white), Coronet (yellow and pink) and Perle Orléanaise (pale pink) are on account of their dwarf habit the most desirable.

For larger, unpruned bushes, Yvonne Rabier (white), Marie Pavie (white and pink), Cecile Brunner (shell pink) and Perle d'Or (yellow) are hard to beat. Léonie Lannesch is a curious terra-cotta variety with a pleasant fragrance.

The great value of these dwarf Polyanthas is their hardiness, their bright colours and freedom and continuity of flowering and their compact habit. All these qualities make them particularly suitable for small gardens. They are, in fact, ideal bedding plants, with the inestimable advantage of being perfectly hardy. As cut flowers they are very gay and cheerful, and all last well in water.

WHITE LADY.

CLIMBERS FOR PERGOLAS AND ARCHWAYS

IN the very large garden a pergola may appropriately be clothed with one kind of climber, and this is often exceedingly effective, as, for examples, the Rose Walk adjoining the Iris garden at Kew and the similar structure supporting a great variety of ornamental Vines running south from the refreshment pavilion in the same gardens. At Bodnant, in the wonderfully beautiful grounds of Lady Aberconway's North Wales home, a pergola solely of Laburnum has entranced thousands of visitors, though few would have thought of using the "Golden Rain," which becomes a tree when allowed to grow naturally, for such a purpose. But under skilful pruning and training it became a complete success at Bodnant. In a smaller garden in Surrey there is a beautiful little pergola of *Wistaria multijuga*, which is exceedingly effective, though, unfortunately, the pergola was not made sufficiently high to permit one to walk comfortably under the long racemes when the *Wistarias* are in flower. The question of head-room is important in relation to the full enjoyment of a pergola and, perhaps in a lesser degree, a climber-clad archway. This must also govern the selection of climbers, as those which should be allowed to hang freely in order to disclose their full beauty cannot well be planted to ramble over pergolas which are much less than 8 ft. high.

Roses are, of course, indispensable for the mixed pergola. Within the limits of their habit of growth the choice of varieties must be a matter of individual taste, but when making a selection it should always be borne in mind that such as *Albéric Barbier*, *American Pillar*, *Bush Rambler*, *Carmine Pillar*, *François Juranville*, *Léontine Gervaise*, *Goldmech* and *Tea Rambler*, to name only a few of the popular varieties, are, while exceedingly beautiful when in flower, purely seasonal and unlike *Ard's Rover*, *Grüss an Teplitz*, *Mme. Alfred Carrière*, *Reine Olga de Wurtemberg* and others, which are more of a perpetual character. Many of the more free-growing Roses, and therefore of great value for furnishing pergolas and archways, are generally somewhat bare below. In the case of the pergola which is associated with narrow borders of Lilies and herbaceous plants a very charming arrangement this is in the nature of an advantage, but when it is purely a pergola it becomes a fault, which, however, can easily be remedied by planting a less vigorous sort with that which will cover the cross timbers. Different shades of the same colour are exceedingly effective or, if preferred, a direct contrast may be provided. For the sides of a gateway or open masonry arch the larger-flowered single Roses are very beautiful, and if it is a southern aspect the *Macartney Rose* (*Rosa bracteata*) is greatly to be recommended. It is a very distinct Rose that in the full sun

becomes exceedingly charming, as also do *R. levigata* (syn. *sinica*) and the silvery pink variety *Anemone*. Other desirable large single Roses

it receives fair attention, it could be planted against the pergola as well as the archway. The *Virgin's Bower*, as *C. Flammula* is often called, bears

abundant trails of fragrant white flowers during the late summer and autumn. Of the large-flowered hybrids the names are legion. The *Patens* group are the earliest to flower, then come the *Florida* varieties, followed by the *Lanuginosa* group and, last of all, the splendid *Jackmani* sorts.

The mixed pergola is not complete without at least one plant each of *Honeysuckle* and *Jasmine*. For general purposes the best flowering *Honeysuckles* are the *Early Dutch* and the *Late Dutch*, but *Lonicera japonica*, *L. sempervirens* and *L. Heckrottii* all have great merits. That largest of all *Honeysuckles*, *L. Hildebrandiana*, is unfortunately only for the most favoured positions out of doors. As a foliage climber the golden *L. aureo-reticulata* is of value and often seen on garden arches.

The common *Jasmine*, or *Jessamine*, was probably the first climber to be cultivated in this country, and its merits are thoroughly well known. But on the pergola it should be kept within bounds or it will encroach on the other climbers. Although strictly they are not climbers, there are two

THE GOLDEN BLOSSOMS OF FORSYTHIA SUSPENS A ENLIVEN PILLAR OR ARCHWAY IN LATE WINTER AND EARLY SPRING.

include the orange-flushed *Carmine Isobel*, the deep brownish red *Moyessi*, *Sheila Wilson* (light scarlet with yellow base) and the pale cream *Una*.

The great family of *Clematis* gives a wide selection of climbers for the pergolas and archways. The beautiful and popular *Clematis montana* is almost too vigorous for the pergola unless it is carefully and systematically thinned after it has covered the allotted space, but is admirable when trained to archways and allowed to hang down in graceful trails. *C. Flammula* is of similar habit, though not so rampant, so, provided

yellow-flowered species which have distinct value for the pergola. *Jasminum nudiflorum* is an old favourite and could well be associated with the white *Jasmine*, when it would furnish the uprights, while the later-flowering species will give its best display along the cross-timbers. The summer-flowering *J. revolutum* is, for some unaccountable reason, a neglected shrub. Its free, yet lax habit makes it very suitable for the pergola and for archways. Its good yellow, fragrant flowers are produced over quite a long period and, being nearly ever-green, is an additional attraction. By judicious

pruning flowers can be obtained along the full length of the plants.

Besides these, what one may term indispensable climbers, there are a great variety of flowering species which will add great interest. *Akebia quinata* and *A. lobata* will readily clothe the pergola, and in a favourable season the flowers will be followed by fruits of uncommon appearance. Of the various hardy *Aristolochias* the Dutchman's Pipe, *A. Siphon*, and *A. moorpinensis* may well be included. *Berberidopsis corallina* is a beautiful shrubby climber for the north or north-west side of the pergola in the warmer parts of the country, and *Bignonia capreolata atrosanguinea* is also for favoured places, though rather hardier. For the warm archway few plants are handsomer than *B. (Tecoma) grandiflora*, which when established produces large racemes of splendid flowers. *Forsythia suspensa* and the even more striking *F. spectabilis* may well be planted to furnish the uprights of any fairly broad pergola.

The fragrant Blue Passiflower is quite hardy in the western counties and in many other parts the roots will survive if they receive a little protection. It is such a beautiful and interesting climber that it might well be tried even when there is some element of doubt as to its hardiness. *Passiflora corulea* grows so quickly during the summer that, although the frosts will often kill the shoots to the ground-level, it will furnish its allotted space and flower freely from midsummer to late autumn. *Periploca graeca*, the Silk Vine, is not very showy, but it is an interesting climber that will grow quickly, though in this respect *Polygonum baldschuanicum* surpasses it and also seems quite indifferent as to soil—it will flourish exceedingly in the most poverty-stricken places. The pleasantly scented, abundant, trailing panicles become almost a cloud of whitish flowers, and the effect is continued, enhanced by a pinkish tinge, on the seed vessels, which persist for a long time. The *Wistarias* are rather better adapted for the archway than for the pergola of mixed shrubs, though they can be used with great effect on the latter structure if the long shoots are regulated as they grow. *Solanum crispum* is wondrously beautiful when it can be grown well, but this usually is only in the warmest part of the country. Elsewhere it should be tried for the brick archway facing south.

Chief among the climbers that are used for their foliage come the many hardy Vines, and these include *Vitis armata* Veitchii, *V. Cognata*, *V. flexuosa* Wilsoni, *V. Henryana*, *V. Thomsoni*, *V. Humberti* and the cut-leaved varieties of *V. vitifera*, the Grape Vine. *Ampelopsis* Veitchii is botanically a species of *Vitis* (*V. monstrosa*), and its value has long been established. A timber,

A PLENITUDE OF BLOSSOM.

WISTARIAS ARE ADMIRABLE PERGOLA PLANTS.

chinensis is a noble-foliaged climber that will rapidly furnish a part of the pergola or an archway with very handsome leaves where ornamental

foliage is esteemed, and it has great value in the pergola scheme; a selection of the many Ives should certainly be included. A. CECIL BARTLETT.

THE CARE OF ORCHARDS

Orchards should be places of beauty and utility, and to achieve both ends they must have summer attention. Hereunder are mentioned a few things that ought to be done now.

IN these days it is not the custom to plant fruit trees in orchards, as was the case a century and more ago, and for this we have largely to thank the introduction of the dwarfing stocks on which trees are now almost invariably worked by budding. These are of compact habit, come into profitable bearing several years sooner than the regulation orchard standard, give a higher average of quality, and are infinitely easier to manage in all the numerous and varied details of treatment.

It has frequently been urged that all the orchards of the country should be uprooted because the fruits are generally round about third grade, are commonly blemished, and the yield is normally biennial. While I should personally, prefer bush trees in practically all instances, I am quite satisfied that the three reasons which have been spread in favour of grubbing are thoroughly unsound. If one wants to find orchards which ought to be destroyed, one can find them in plenty—congregations of gnarled old trees to which a thought is never given and which, consequently, give unspeakably wretched returns.

There are, however, many orchards up and down the country that have been planted intelligently and which are capable of developing grand burdens of fruit season after season, and for such it were the height of folly to advocate destruction. On the contrary, they deserve to be cared for to maintain them when they are at a fair standard of excellence, and to be specially considered where the prospects justify exceptional attention.

This is not, as all readers of THE GARDEN know full well, the period of the year when serious renovation work can be put in hand, but it is indisputably a period when the burdens of the year may be substantially helped to the ultimate benefit of the cultivator, and when the foundation for succeeding crops can be materially strengthened.

Putting on one side the disadvantages and difficulties of pruning, cleansing, gathering and other cultural details of standards compared with bushes, since this is not a moment when they can be discussed with practical utility, let us consider the things which should be done during the immediately ensuing two months in direct aid of the present principally and of the future secondarily.

At the height of summer, when standard and half-standard trees are in full growth, carrying heavy burdens in the fat year and building up to the point of perfection blossom buds in the lean year, they suffer most of all from lack of food, with lack of light and fresh air as an equally prejudicing factor in those instances where the buds are so dense that they cannot be seen through clearly at all times of the year. We can deal in varying degrees according to circumstances with the former, but we can do nothing in respect of the latter beyond the prompt removal of dead wood whenever it is seen. It is true that most orchards are "fed off," but the amount of food resulting from this, except, perhaps, when pigs are abundantly utilised for the purpose, is comparatively small and totally inadequate to meet urgent demands.

One of the most desirable things to do, then, now and onwards to the middle of September

is to use fairly strong liquid manure with a generosity which would lead inevitably to considerable trouble if it were given to bush trees in plantation form. The difference lies in the fact that in the orchard it is safe to assume that the grass will appropriate not less than half the nutrient value, whereas in the plantation it is not an insurmountable difficulty to ensure that nearly all the benefits go to the trees.

In many orchards, one might say the majority, it is the custom to keep a circle cut out round the bole of each tree in which weeds are not permitted to grow, and great virtue is set upon it. If the circles were increased in size annually with top growth and their margins were maintained at the full spread of the branches, there can be no doubt as to their value and importance, but the 3ft. rings which are usually seen serve the purposes of encouraging a little fresh air to find its way into the soil and preventing the serious accumulation of rubbish at the base of the boles, thus substantially reducing the harbours to so beloved of the pests of fruit trees; beyond those two things, certainly important, they are of no appreciable value. They are called attention to at this juncture in direct association with feeding because it is by no means unusual to see amateurs pouring on liquid manures and dredging on concentrated fertilisers in the hope that the trees will derive full benefit. This they will not, cannot, do. It is obvious that there must be some spread of the moisture as it passes down, but the bulk will go direct, and it is fair to estimate that half the benefits will be lost, while if the soil happens to be on the dry side the proportion wasted will run to not less than three-quarters.

The active feeding roots of the trees are principally approaching to beneath the extreme spread of the branches, and they extend always a short distance beyond them. If it is desired, therefore, to give sustenance which will be almost instantly available for appropriation, it must be applied at, or approximately at, the position indicated. With limited circles this is impossible, and extending beyond come the grasses, so that one is forced to bore holes about 2½ in. to 3 ft. deep at similar distances asunder and 5 ins. or 6 ins. in diameter at the top over the extremes of the comparatively wide area and to fill them repeatedly with the liquid at command at intervals of ten to fourteen days. Then an immense amount of good will be done to the crop of the season and to the fruit-buds for next year which are building up to perfection. It must be borne in mind, though it is improbable that the reminder will have real substance this season, that when the soil is dry it must be efficiently moistened with pure water before liquid manures are used to reduce the loss of the foods they contain and to obviate any danger of the strong liquor used damaging any tender roots with which it may come in contact.

It is imperative, too, that cleanliness shall be maintained at the foot of the trees, and also, as far as it is feasible to accomplish it, in the branches also. If it is convenient to turn in a flock of fowls, by all means do it, because they will prove to be assiduous searchers for grubs, and consequently will reduce the trouble from insect

attacks in future seasons. Failing these industrious scavengers, which give at any rate some financial return for the work they do in the form of eggs, a strong, sharp rake should be used with frequent regularity to remove every scrap of rubbish not from the neighbourhood of the trees merely, but right out of the orchards; and the surrounding hedges and ditches must similarly be kept in scrupulously clean condition for the same reason—reduction of future danger from insect enemies.

If woolly aphid or American blight is a trouble of the moment, spare no efforts to eradicate it as quickly as possible. A touch of a drop of methylated spirits, sweet or linseed oil will account for all those which are readily accessible, while for the heads Woburn Tobacco Wash used as the manufacturers instruct, will be found invaluable and will do no harm even to young leaves. It should be sprayed, not syringed on. In the routine process of cleaning fallen fruits will be removed, but in the intervals between rakings all such ought to be picked up the instant they are seen, for destruction or consumption, this being of outstanding importance when fruits are falling as a result of codlin moth attack; the grubs leave the fruits shortly after they fall, and are then much more difficult to deal with.

A middle of September task which must not be forgotten in any circumstances in orchards is the attachment to the trunks and to the bases of the main branches of sticky or greasy bands which will prevent the upward march of the wingless female Winter and other injurious moths into the heads of the trees. Notwithstanding the fact that the bulk of the enemies will be caught before the end of November, it is most wise to keep the bands fully effectual until at least the middle of next March by renewals which will vary in frequency of necessity with the material used and the weather. W. H. LODGE.

A CHARMING NATIVE

I COULD write ever so much about *Echium vulgare*. It would make a good text for a long sermon, but although I am going to divide what I have to say into three heads, I hope to put it all in a moderate-sized nutshell. First, *Echium vulgare* is nothing but the name of a British plant written botanically in Latin. Those familiar with our wild flowers know it as Viper's Bugloss. "Are not Abana and Pharpar, rivers of Damascus, better than all the waters of Israel?" How many of our native plants are neglected seemingly because they are native? Viper's Bugloss is one. This is very strange, because real blue in flowers is uncommon. Secondly, Viper's Bugloss is a splendid plant for cutting. Its 18 in. to 2 ft. long sprays are grand in good-sized vases. The buds open just as if they were buds of a *Gladiolus*. In the cutting quarters of a large garden a bed of it would be found very useful. Thirdly, its English name is a good instance of the once fashionable and all-important "doctrine of signatures." I must not start on this fascinating subject. William Coles, whose "Adam in Eden" may be described as our English text-book, shall be my spokesman and say all that need be said in a general way: "The Signatures likeness are taken notice of, they being as it were the Books out of which the Ancients first learned the Vertues of Herbes; Nature or rather the God of nature having stamped on divers of them legible Characters to discover their uses." Thus because the seed of our plant has a distant resemblance to the head of a viper, it was held to be a cure for the bites of snakes; just as those plants with yellow juice were said to be good for jaundice. MAELOR.

LAXTON'S STRAWBERRIES

THE Strawberry is the one fruit for which space can be demanded with complete justification in all gardens, wholly irrespective of size. It is true that the usual practice is to cultivate the plants in cycles of three years, in the maintenance of which the oldest bed is grubbed annually and a new one planted to take its place. Under rational treatment, especially in regard to the quantity of manure incorporated with the soil when the fresh bed is in course of preparation, the system gives excellent results and, broadly speaking, it may be said to be the best. Nevertheless, where it is difficult or impossible to ensure satisfaction by this method owing to the arrangement of other crops, it is a simple matter to produce magnificent yields when the plants are utilised as edgings to

since their nurseries may be fairly regarded as the most representative breeding places of this fruit in the British Empire. Thence have come, to find ready welcome in the gardens of the world during the past three or four decades, most of the finest varieties in cultivation. An excellent foundation for the great work was laid by the late Mr. Thomas Laxton, it is maintained in the second generation by Messrs. William and Edward Laxton, and in the third generation by Mr. Edward Laxton, jun. There are scores of acres devoted to standard varieties, comparative novelties, others of proved merit which are being increased until the stock is big enough to justify distribution, and to seedlings of varying ages which have not yet won their spurs—there are thousands of these in the stage of individual plants of which every cross is recorded

A PROBABLE SUCCESSOR TO ROYAL SOVEREIGN, STRAWBERRY THE DUKE.

a path, fruited once, and then consigned to the rubbish heap. This is often, in fact, the only practicable manner of providing the requisite accommodation in very small places.

No matter, however, what system of culture may be chosen, it is most necessary that the variety or varieties grown shall be of the best. The average yield to each plant must be a good one, the fruits must be handsome in shape, rich in colour (though this may vary from light to dark), and, perhaps most important of all, seeing that we of *THE GARDEN* grow the Strawberries to eat ourselves and not to dispose of in the markets to other people, the flavour must be rich, with a distinct tendency to cleanse, not to cloy, the palate. Sufficient importance is not attached by the majority of amateurs to the fact that when a variety is grown and propagated in the same garden year after year there is a marked deterioration in vigour, and that it is not merely desirable but very decidedly advisable that fresh stock shall be purchased at limited intervals from a different soil and climate if the best results are to be achieved consistently.

With a view to ascertaining whether there was anything of conspicuous merit among the new or comparatively new varieties, a visit was paid recently to Messrs. Laxton Brothers', Bedford,

and the merits or demerits of which are accurately entered in the firm's books. Many, not all, of these were closely examined, and a few, a very few, were tasted, and it must suffice to say that some were delicious and others were the reverse.

CORRESPONDENCE

USE OF THE R.H.S. HALL.

My council have had under consideration the charges sought to be imposed on kindred societies for the use of the Royal Horticultural Society's Hall, which, as you know, was built by public subscription and intended to further horticulture, and have made arrangements to hold their shows elsewhere in 1923.—COURTNEY PAGE, Hon. Secretary, National Rose Society.

IRIS NOMENCLATURE.

WHY Messrs. G. G. Whitelegg and Co. should consider it necessary to "broadcast" the news that I am associated with the firm of R. Wallace and Co., Limited, I do not know. After fifteen years connexion with that firm it would be hopeless for me to prove an alibi, even

Considerably more attention was directed to the comparatively new varieties already on the market, and it was decided after many tests that Marshal Foch, Sir Douglas Haig and Titbit were of conspicuous merit. Each has an excellent constitution, and, while it cannot be claimed for them, or for any Strawberry known, that the results will be equally satisfactory on all soils, these have been so generously praised in letters from expert gardeners in all parts of the British Isles that those who have not yet given them a trial need not feel the slightest hesitation in doing so. The first named ranks with the maincrop sorts, the second named is notable for earliness, while the last named is a maincrop, perhaps just on the small side, but it has an exceptionally rich flavour—it was, in fact, the finest of the group in this respect that we tasted, proving superior to even the great Marshal Foch.

Mention must on no account be omitted of the novelty of the year—Abundance. This is a Strawberry of Strawberries, and if it maintain in all soils the merits which made it so outstandingly apparent among the hundreds of thousands of plants in Goldington Road Nurseries, Bedford, it will soon be King Strawberry of our gardens. It belongs rightly to the mid-season section and is, naturally, extremely robust and vigorous in habit, characteristics which should serve to warn growers to guard against excessively manuring the ground in preparation for it. The glowing scarlet, very firm fruits are wedge-shaped, rather above the average in size, and the flavour is truly excellent. Add to these proud recommendations the fact that the plant is a very heavy cropper, and it will be agreed that it is justifiable to say that Laxton's Abundance is a Strawberry fully entitled to a trial in every garden.

Just a word to those who have more space in their gardens than is necessary to meet personal requirements. If they want to grow half an acre or an acre of Strawberries for sale let them go for The Duke. It is early, a grand cropper, firm and therefore a good traveller, and if the flavour is not that of a Marshal Foch or a Titbit it does not matter very much, since someone else is to eat it.

Laxtons do not, as their supreme position as introducers of Strawberries has led many people to suppose, restrict their attention to this fruit; on the contrary, they have given us marked improvements in Apples, Pears, Currants, Goosberries, Raspberries and other kinds; but while we stand on the threshold of the Strawberry planting season, the kinds just named do not come to that season until the autumn and winter, and reference to them may, therefore, usefully be left over until that practical period. H. L.

if that association were a crime. In any case, if it is a crime, I am proud to be able to plead guilty.

With reference to the remark about the manner in which they have dealt with *Iris ochraceo-cornulea* in their *Iris* catalogue, I have no doubt that this is quite satisfactory. In any case it is a matter of indifference to me.

Reference to my notes on this question must convince everyone interested that nothing that I have written was intended to cast an aspersion on either their commercial integrity or business procedure. I have the highest opinion of both.

One point, however, in the letter that does concern me is the accusation of my lack of veracity, and this I am compelled to deal with. They say: "This *Iris* has never been offered in any *Iris* catalogue hitherto published in this country, on

the Continent, or in America." One example will be sufficient. I have before me two successive editions of the catalogue of Messrs. Millet et Fils, a French firm of some considerable standing, and in both I find the following: in the second edition the page is 13:

"OCHRACEA-CŒRULEA (Denis) très tardif, jaune citron et mauve lilacé, violet cobée, coloris original" (followed by price).

The next statement made in their letter is that "the name Sunset has not previously been appropriated for any other variety in any Iris catalogue with which we are familiar, nor does it appear in the American Iris Society's List of Irises," etc. I do not know which edition of the Iris Check List they possess, but in the copy that I have before me, on page 34, in the second column, the thirteenth name down the list is Sunset T. B.

With reference to their concluding remark in this paragraph. They have the indisputable right to name any number of different plants with the name "Sunset" if they wish to do so; whether it is wise or conducive to the avoidance of complications is another matter.

I might point out that, in addition to being registered in America among the varieties in commerce in 1919, see Iris Check List, page 18, column 1, thirteenth name down the list (curious how this 13 recurs), and having been certificated in London, it has also been certificated by the Société Nationale Horticole de France under the name *Ochracea-cœrulea*. This latter award had escaped my notice when writing previously. Thanking you in anticipation for your courtesy.—
GEORGE DILLISTONE (of R. Wallace and Co., Limited, Tunbridge Wells).

BESCHORNERIA AND LITHOSPERMUM.

WITH moderate shelter the *Beschorneria* should be easily grown in the South. Here, in a valley where a small degree of frost is injurious, owing to the proximity of the Avon, *Beschorneria Roseana* is scarcely affected even by a sharp winter spell, while such plants as *Tricuspidaria*, *Euryphia cordifolia* and most of the *Hydrangeas* are severely cut. South Devon is a name to conjure with, and ten miles to the south of this place Oranges, Lemons and Citrons are growing in the open against a wall—but not here!

As to *Lithospermum*, whence comes the superstition that lime is obnoxious to it? The race is a passionate lime-lover. I have, to prove it, planted *Lithospermum Heavenly Blue* on a mass of little else but lime rubble. It has been there for a year, where, despite the drought, it has flowered, and its leaves are dark green and vigorous. No! what *Lithospermum* dislikes is winds or draughts. If in an exposed position it is then that it exhibits those blackened twigs and leaves which are often the despair of those who would like to grow it well.—T. A. HYD., *Avonack, S. Devon*.

TWO BLUE ANNUALS.

IN William Robinson's "English Flower Garden," which I should not criticise because the talented author presented me with my copy many long years ago, the *Phacelias* are described as "Californian hardy annuals: none of the cultivated kinds very important." *Phacelia campanularia* was introduced in 1852, and the first edition of Mr. Robinson's work was published in 1857, and it is possible this particular *Phacelia* would not be widely known. I consider it the brightest and best of all hardy blue annuals. The shade is pure ultramarine ("Repertoire de Couleurs," 213, 1); the pure white anthers are an added attraction in the early stage of the flower. Sown

in the open in early April and thinned to 4ins. apart or even 6ins., it will flower during the whole of June and July and longer in the North.

In August of last year when spending a holiday at Cruden Bay, Aberdeenshire, I formed a higher opinion than I previously held of *Nemophila insignis*. On light soil in the pure northern air nothing was prettier in the gardens than this *Nemophila*. I know it is a common thing and was largely sold in penny packets before the war—two-pence now, please—but many common things are beautiful. The colour is the brightest sky blue with white centre, but the general effect is blue. It can be sown either in autumn or spring and ought also to be well thinned out. It is simply ruining annuals to sow them, as is so often done, like Mustard and Cress and leave them unthinned. I have an annual border at present 25yds. long with seventy to eighty varieties in it, and it is a continuous interest and pleasure.—
W. CUMBERSON.

THE BOUGAINVILLEA.

ONE reads so often that *Bougainvillea glabra* should be hard pruned in the same way as a Grape Vine that I am enclosing a photograph I have taken of a plant growing in a small tub

AN UNPRUNED BOUGAINVILLEA.

which has been left quite unpruned. This shows the great mass of flower and beautifully coloured bracts given by the small side growths. It stands on the back stage of a greenhouse and covers a space of about 15ft. by 4ft. It is used to cover the wall and is not trained on the roof. For many weeks it is a very fine sight and the admiration of all who see it. In other respects it is treated as usual—dry during the winter months and an abundance of water through the summer. Seeing how easy and accommodating it is, and how little it is troubled with insect pests, one wonders why it is not used more freely for covering walls, roofs and pillars in conservatories and greenhouses where but little heat is given. I am told by those who have spent many years in the Argentine that it is a great favourite there and much used for training on houses. It will cover a very large space and is never pruned. Its popular name there is Santa Rita. As the winter there is dry and

there is a heavy rainfall in summer, the conditions coincide with those we give them.—H. C. W.

THE SKUNK CABBAGE.

I ALSO have been interested in the references to the "Skunk Cabbage" of British Columbia. I brought some back with me, and then further roots were sent me in 1913. All have grown successfully and without any "nursing" right from the first and are thoroughly established by the bank of a pond, some in the water, some by its side, in Sussex. (I abstain from mentioning the locality: enthusiasts and others are so fond of trespassing and taking samples of uncommon plants.) They bloom well; each clump had four or five yellow spathes this spring, and very handsome they are, reflected in the water. The only damage they have had is from late frosts, which catch the tender leaves. I think the clumps are increasing—the drought last summer was a setback—and some must have seeded.

In THE GARDEN for May 6, 1911, there is notice of the Skunk Cabbage under the name *Lysichiton camtschatense*; in your issue of July 15, 1922, you call it *Symplocarpus foetidus*. Both are jaw-breaking, so better keep to the "Man-in-the-Street" nomenclature, Skunk Cabbage.

My garden also boasts of a fine British Columbia Dogwood (*Cornus Nuttali*) and a Vine Maple, both brought over as tiny plants and now about 15ft. high and blooming well.—D. E. B.

[*Lysichiton* and *Symplocarpus* are distinct plants, the latter being the Skunk Cabbage of North America.—ED.]

ROTATION OF CROPS.

I HAVE no quarrel with rotations in the vegetable garden, but question their practical necessity. They are, however, so held up as a fetish that cultivators of small areas are driven to the utterly erroneous conclusion that failure is sure to result if one particular kind occupies the same site even a second season and that real success can be insured only under three yearly, four yearly and, according to some writers, five yearly rotations. In restricted areas divide the space into two approximately equal portions, making due

PLANTS FOR A SMALL MORAINÉ GARDEN

(Continued from page 363).

SAXIFRAGES.—Moraine conditions are indispensable for many of the Kabschias and other dwarf species and the innumerable hybrids that have been brought out in recent years, some of which are really valuable additions and others not worth a place along with the many beautiful alpine species.

regions in which they are located. Of all the Saxifrages tried only two have really been failures, and with those exceptions the Saxifrages mentioned in 1917 are still in existence, for the most part in the identical positions, very much increased in size or would have been if they had not in some cases been pulled back.

AMONG THE MOST INTERESTING OF SAXIFRAGES, *S. GRISEBACHII*.

Saxifrages are always interesting either in leaf or flower, and can be seen to great advantage on an island moraine. The upper portion of the moraine is almost fully occupied with Saxifrages, mostly the smaller ones. They commence to flower very frequently in January (January 1 this year), and there is a continuous succession up to the end of June, when *S. cochlearis* and its various hybrids are at their best. No protection is needed for the plants in the winter if the drainage is sharp, as it should be; but the earlier-flowering plants are better with glass protection over them when in flower, the weather at that period being so uncertain, and by this means the flowers are maintained in good condition for a considerable period, which is especially desirable to some of us who only have an opportunity when days are so short of seeing them at the week-end. The plants are usually mulched with crushed old mortar after flowering and the dead flowers cut off, which helps the plants if they have been flowering freely to regain their vitality. They also require water at the roots (not on top of the rosettes, especially if sunny) at this period, particularly if dry, as it frequently is in my district. A little shade is also requisite for a small proportion of the species. This can be obtained by placing a small rock alongside to keep the direct sun's rays off for a part of the day, conditions many of them have in their native habitats, where the hot sun may only be on them for two or three hours each day owing to the sharp contours that are characteristic of the mountainous

S. Bursariana magna. Quite one of the best of this group, which has flowered freely year after year until this spring, when it failed for the first time to do itself justice, probably due, to some extent, to the very dry summer of last year and to the plant having got rather large, the tufts having worked somewhat loose in the centre and should have been opened out and top-dressed. This has been done now, and it seems to be recovering. I had the same experience with *S. Paulinae*, quite one of the best of the yellow hybrids, in the previous year, but it has fully recovered and flowered fairly well this spring, being at its best about April 23. *S. B. magna* has flowers almost, if not quite, as large as *S. B. Gloria*, but on shorter reddish stems, which if exposed stand the rough weather much better than *S. B. Gloria*. A glorious form of the type, the first named is the latest of the three to come into flower. This year it was in flower on March 9. *S. B. Gloria* on March 1, and the type opened its first flowers on January 1, at which time the flower-buds of the others were well developed, but owing to the continuous period of low temperatures they practically remained dormant for weeks.

S. casia.—This desirable tiny grey-rosetted species has died out with me on two occasions, never lasting more than two seasons. I hope to give it another trial, and will see if protection from winter rains and freedom from lime, which it possibly resents, will prove satisfactory. A very near relative and quite as pretty, *S. diapienoides*, has proved quite at home over a period

allowance for the few essential permanent crops. On one section put the Potatoes and Onions, which might well be treated as permanent except in the case of a bad attack of mildew, and on the remaining moiety all other crops; reverse the positions each year and the old-fashioned simple rotation is achieved, with imperfections, of course, but nevertheless satisfactory for general usage. The one disadvantage of non-rotation is that the value of unappropriated food elements is not always secured and the system would, obviously, fail wholly where shallow soil working was practised. I incline to the view that Miss Price-Davies (page 346) is in error or mis-states her point when she says that in "wet weather . . . the nourishment of the plant would then come from above and from its immediate surroundings." Is it not true that imbibition by the root hairs of the elements of plant food occurs only when the moisture is ascending and not when it is descending? Surely save in rare torrential rainfalls there is always some capillarity? If the fact is as suggested by your correspondent, plants would continue to feed in a water-logged medium; whereas, owing to the root hairs perishing, they starve amid plenty, precisely as happens in a quite dry soil. Draw and push hoes have had places in every garden in which I have worked for nearly half a century and while the latter has had its value it has not once entered into serious competition with the former; the trouble is that few amateurs manipulate the draw hoe with that smoothness which carries it slithering sweetly, rapidly and effectively through the soil as the professional does with inherited naturalness.

In my experience neither two years, nor three years, nor any more years is a sufficiently long interval in "club" localities. The disease may come in one year or in twenty years, but in the latter case the chances are that the spores will be mechanically borne and for this reason, if for no other, it cannot be prevented absolutely. I have had to contend with it in light Surrey land, where we earthed every plant up with good compost, packed firmly, and kept moist by watering as necessary, and freely confess that it is the worst garden enemy with which I have fought doughty battles, and, incidentally, generally lost.—W. H. LODGE.

YELLOW ASPHODEL.

THE old Yellow Asphodel, *Asphodeline lutea*, still frequently called *Asphodelus luteus*, is not by any means so common as it was at one time. It is generally met with in the form of a clump in a border with a few spikes of its yellow flowers standing well up to a height of 3ft. or so. The other day I came across a mass of plants upwards of a hundred in number, and although they were in somewhat formal array, they gave me an idea of what this *Asphodeline* might be when planted among masses of other plants in a wild garden. The plants were well grown and were upwards of 3ft. and nearer 4ft. high, and were well flowered. Stiff-looking as were the spikes, one can appreciate how such a mass would look set among other plants and how effective the yellow flowers would be amid greenery. I have not found it a free plant in poor soil, but in a good fertile loam it is much more satisfactory.—S. A.

of years and flowered beautifully in early May. Another very similar species, *S. Tommasiniana*, which I have had three or four years, keeps quite healthy, but has never flowered yet.

S. Burnata.—This natural hybrid, which has *S. cochlearis* as one of its parents, has very beautiful delicate sprays of *S. cochlearis*-like flowers, but on a much larger scale; it has flowered profusely this season and being one of the latest Saxifrages to flower is just going over, at the end of June. Given a position on the outside, when its pendulous flower sprays can be thrown clear of the side, it will show its delicate beauty to perfection.

S. Faldonside.—Still one of the best of the yellow-flowering *Kabschias*, with large sized, short stemmed citron-coloured flowers. While I still have the original stock, this is due to my taking off a portion of the original plant, which died out, which it seems to have the habit of doing and usually unexpectedly. It has not flowered for the last two years and this may be due to the flowers being frosted when in bud two winters ago and the resultant check.

S. Grisebachii.—This species and *S. cœsia* already mentioned, are the only real failures that I have had out of a large number of species and hybrids that have found a place among my Saxifrages. Apparently a satisfactory position has not been found for it yet as it is a plant that should prove amenable to the conditions provided; one of the difficulties has been to prevent it from being loosened out in the winter months without using special protection. It is much the finest of the "Engleri" Saxifrages and its best forms are extremely interesting, with its crozier-like red stem which gradually unfolds itself and red flowers.

S. Petraschii is still quite happy with its white crinkled blooms of good size and substance and, following after the *S. Burserianas*, is quite among the best of the group. *S. Salomoni*, quite attractive and easy, with its paper-white flowers on reddish stems, has the cushion grey and compact. When first planted it was somewhat shy in flowering, but recently it has flowered exceptionally well. The flower stems are somewhat long and delicate, and it is likely to suffer damage from the stormy weather that very frequently happens when it is in flower, usually about March. *S. Irvingii*, another hybrid with *Burseriana* as one of its parents, has been raised since Mr. Farrer's list was published, otherwise it could hardly have been left out of the select "Fifty"; it has very compact grey spiny foliage, from which are thrown up on short stems delicate rose-tinted flowers, deeper at the base of the petals; it always flowers very freely, in fact the cushions usually are absolutely covered with the delicate rosy pink flushed flowers. *S. lilacina*, with its hard, very compact tiny green rosettes, has slowly increased until it is now quite a nice sized plant, which in recent years has given bountifully of its somewhat uncommon rosy lilac flowers. This is a Himalayan species and seems best planted in a position shaded from the sun for a good part of the day and in one that ensures somewhat more moisture than is usually allowed.

S. Boryi.—This has increased considerably and to me seems to be very close to *S. margnata*, with small green silvery-tipped rosettes and its clusters of beautifully white, good sized flowers carried well on a sturdy stem and is quite one of the most satisfactory of the Saxifrages. It usually flowers in early April, about a month later than *Burseriana*, and lasts for quite a good time. *S. Haagi*, with hard green, very compact rosettes, very similar to *S. sancta* in many respects and quite as easy, but the deep yellow flowers have much larger petals, which are carried on sturdy stems and the flowers resist bad weather much better than many species that flower about the same period. *S. apiculata*, with its primrose

yellow flowers, is still quite one of the best and easiest, and the white form of *apiculata* is equally good; both usually flowering very freely, which is not so usual with the *S. Elizabethæ* section. *S. Boydii alba* is a good early-flowering plant; *S. coriophylla*, which is out when *S. Burseriana* is well over and *S. scardica*, usually later still, are worth growing, all helping to lengthen the flowering period.

S. aretioides.—This compact Pyrenean Saxifraga, with its deep bright yellow, short stemmed flowers, is one of the latest to come into flower. My plant was taken out of a friend's garden when on its "last legs," only one cushion apparently having life in it, and planted on the moraine, where it slowly recovered and has grown into quite a nice plant.

S. S. cochlearis and *cochlearis minor*, the latter with the pleasant grey rosettes much smaller in fully exposed positions, give generously of their delightful flowers year by year. Of the Engleri section, *S. Stribnyri* makes rosettes fairly freely, but it has not flowered for some years. *S. Frederici-Augusti* failed to flower this spring, although it has flowered in previous seasons.

S. Bertoloni.—This hybrid has flowered freely both this year and last. *S. media*, the Pyrenean red-flowered species has just been planted. While the above are all interesting, none of them is nearly as fine as *S. Grisebachii*, before mentioned. The moraine is the most suitable position for the tiny silver-edged *S. Aizoon baldensis*, with its pretty flowers; some of the better *S. Aizoon* varieties find a place and are desirable for lengthening the Saxifrage flowering period. Among the best are *S. Aizoon rosea*, *S. A. lutea*, *S. A. pectinata*, etc. The very fine hybrid "Dr. Ramsay" (*longifolia* × *cochlearis*), finds a place, with its interesting rosettes and beautiful flower spikes, as does also *S. Kolentiana* (possibly *cartilaginea*), an Asia Minor plant with long narrow pointed leaved rosettes and pinkish flower spikes.

S. retusa.—This minute running oppositifolia-like plant, which has been planted for some years, flowered for the first time this season, the deep ruby red flowers being distinctly pretty.

T. ASHTON LOFTHOUSE

To be continued.

GARDENING OF THE WEEK

FOR SOUTHERN GARDENS.

The Kitchen Garden.

Summer-sown Cabbage.—The sowing of Cabbage to yield produce for spring and early summer is an important point where the supply of kitchen vegetables is on an extensive scale. The actual date of sowing may vary in some districts, but I do not think a few days either way will make much difference. A point I think of more importance is the selection of suitable varieties, such as Flower of Spring, etc. Two separate sowings should be made, and the first one should be in by the early days of August, followed by another one about the middle of the month.

Vegetable Seeds.—The clearing of early vegetables, such as Peas and Potatoes, will provide a suitable piece of ground for sowing quickly-maturing varieties of several vegetables which will come in very useful during autumn. Where the soil is cold and retentive, only a partial measure of success must be expected. Among other kinds, mention may be made of Peas, Spinach, Carrot, Beet and French Beans, choosing a warm spot for the latter where covering can be given later if necessary. If Cabbage seed is sown thinly and not transplanted it is possible to have plants with nice young hearts during November and December.

Winter Greens.—Kale, Savoy or other kinds should be looked over and have all deficiencies made good and additional plantings made where necessary.

Early Potatoes may be lifted even though the tops have not died down and will keep well if care is taken not to damage the skins. If any of the tubers are required for seed purposes they should be left outside to ripen a little before being placed in their storage quarters.

The Flower Garden.

Perennial Lobelias, such as *L. cardinalis*, require re-stocking to some extent most seasons, and the present is a suitable time to sow seeds for this purpose. Sow in pans or boxes filled with sandy soil, and place in a cold frame for germination. When the seedlings are strong enough prick out in boxes or in a shallow frame, shading from bright sunshine until established. Given a little attention, nice plants will be available for another season. The wintering of the plants may be done where grown, remembering that dampness is the greatest enemy.

Hydrangeas.—To maintain the stock of plants necessary for vases or tubs it is advisable to have a continuous supply of healthy young plants coming along. August is the proper time for securing cuttings to strike and grow on for this purpose. The partly ripened shoots may either be placed singly in small pots or about three may be put round the sides of a large 60 sized pot. Treated thus and grown on undisturbed it is soon possible to have nice bushy plants. A

slight bottom heat will give a quicker "strike," but later the plants should have cold frame treatment with plenty of light and air.

Antirrhinums.—To provide a stock of plants for flowering early next summer the seed must be sown during August, and for preference not later than the middle of the month. Sow thinly in shallow boxes or a cold frame, and prick the seedlings out as soon as ready to about 4ins. apart. This may either be in cold frames or on a fairly warm, well drained border where some protection may be given when necessary. The plant's greatest enemy during the winter months is dampness.

Fruit Under Glass.

Early Vines.—As soon as a clearance of the fruit from the plants is made steps should be taken at once to ascertain the condition of the borders, and if necessary a thorough watering be given. Should the crop have been a heavy one, or if the Vines are at all weak, manure water should be used. Keep all lateral growths cut off, and concentrate all the plant's energies upon the ripening up of the wood by airing the house freely day and night. If red spider is present it may be checked by syringing well with an insecticide, and a few good drenchings of water through a hose.

Pot Trees.—Trees in orchard houses or elsewhere, carrying heavy crops of Apples, Pears, etc., should receive regular assistance with manure water until the ripening period is apparent. Unless suitable supports in the way of nets are in use for the fruits, the latter must be securely fastened on with strong, broad raffia.

The Hardy Fruit Garden.

Morello Cherries.—It is not too late to help these with supplies of water if thought necessary, but probably other varieties not yet gathered had better be omitted, as it is now too late to do so with safety, owing to danger of the fruits splitting. Give the trees cleared of their crops a good cleansing if necessary, and cut away growth not required.

H. TURNER

(Gardener to the Duke of Northumberland),
Albury Park Gardens, Guildford.

FOR NORTHERN GARDENS.

The Kitchen Garden.

Lettuce.—Make a larger sowing than usual at this time for autumn use, choosing a convenient border for the purpose. Sow in lines 1ft. apart, thinning out to 4ins. apart in the rows. Lettuce are generally more satisfactory if sown where they are to remain, and if accorded considerate treatment will produce crisp and tender plants of good size.

Spring Cabbage.—The second and in many gardens the most important sowing of spring Cabbage should now be made. Choose an open

position, and sow thinly in rows 1ft. apart so that short, sturdy growth may result. Sutton's Flower of Spring is undoubtedly one of the most suitable varieties for sowing now, as it possesses all the qualities that go to make a good spring Cabbage, being very hardy, heading quickly, and not being so liable to "bolt" as some sorts. It has few outer leaves and proves of excellent quality when cooked.

General Work.—The present is one of the busiest seasons of the year in the kitchen garden, as crops of various kinds are going over, and where time and circumstances permit, the ground should be cleared and utilised for catch crops, such as late sowings of Spinach, stump-rooted Carrots, Globe Beet, etc. In regard to late Peas that have made extra strong growth, these should receive additional support, and thus save the crop from damage by the autumn gales. Keep all ground free from weeds and well hoed when the weather is suitable, resorting to hand-weeding when the weather is showery.

The Hardy Fruit Garden.

New Plantations of Strawberries.—Where it is desirable to lay down new beds of Strawberries with expectations of securing fruit from the young plants next season, no time should be lost in having the work carried through. It is essential that good strong runners be secured and that the ground they are to occupy should be in good heart. The Strawberry likes a deep soil and will revel in a part that has been deeply dug and well manured for earlier crops. Set the runners out in lines 2½ft. apart and 15ins. apart in the rows. Strong-growing sorts may be allowed 3ft. between the rows and 15ins. between the plants, but for most varieties the first mentioned distance will be found suitable. After root action commences the ground should be kept well hoed and every encouragement given the plants to establish themselves before winter.

Fruit Under Glass.

Peaches.—In early houses where the fruit has been gathered all unnecessary wood should now be cut away and the trees subjected to a thorough washing with the garden engine or syringe. Where traces of red spider are noticeable, means should be taken at once to eradicate the pest. Use one of the many reliable preparations sold for the purpose, taking care to see that it is applied to every portion of wood and foliage. Allow abundance of air both day and night, and thus ensure short-jointed, healthy fruiting wood. Examine the border and see that the roots do not suffer from lack of moisture.

The Flower Garden.

Pinks.—Cuttings of these fragrant and free-flowering plants should be inserted without delay. Utilise a cold frame for the purpose, and dibble the cuttings firmly into a mixture of leaf-mould and sharp sand. Pinks are greatly favoured for planting on the margins of borders, the variety Mrs. Sinkins being singularly effective when planted in conjunction with *Nepeta Mussini*.

The Rock Garden.—Cuttings of such alpine plants as *Dianthus*, *Pboxes*, *Androsaces*, *Saponarias*, *Drabas*, *Saxifragas*, *Linarias* and numerous others should now be got in, and in this way the stock for replenishing or augmenting existing groups next year will be kept up.

Seedling Pansies.—Seed of this old favourite may be sown now on a light border in the open, or germinated in a cold frame and planted out in nursery lines, where they may remain until transferred to their flowering quarters. Treated thus they will produce a mass of bloom during spring and early summer.

JAMES MCGRAN

(Gardener to Sir Henry H. Houldsworth, Bart.),
Cobham, Kilmarnock.

FORTHCOMING EVENTS.

August 1.—Royal Caledonian Horticultural Society's Meeting.

August 2.—National Viola and Pansy Society's Show.

August 3.—Taunton Deane Horticultural Society's Annual Show.

August 4.—Bradford Hospital and Convalescent Fund's Show (two days).

August 5.—Auchencairn Horticultural Society's Show.

Beauties and Beasts at Cambridge

THOSE whose knowledge of Cambridge is only that of a bird of passage know that there are always beauties in the gardens of the splendid colleges and private houses and that beasts are numerous on market days, but the richness to the point of embarrassment of both have never been equal on any one occasion to that concentrated at the Royal Show. THE GARDEN has nothing akin to the beauties of the beasts (if it had, a more knowledgeable pen than the present one would be needed to describe them), but it is rather, mother, brother and sister of many of the finest gardens in the land and is, therefore, in intimate relationship to the beauties of the flowers, and it is to these that attention will be drawn briefly.

The two marquees of noble proportions were disposed to form a gigantic capital T, the one entrance to which was approached between fruit trees from Laxtons and Carnations from Engelmann planted in beds, doubtless to create the imperative good first impression; anyway, that is what they did. Within was a blaze of colour, relieved from the positively plethoric by Pulham's delightful little rockery, Ellison's cool Ferns and Palms and Miss Thompson's quaint and varied Cactaceous plants. Repose to the eye, with, perhaps, a whetting of the palate, came, too, in admirably grown fruit trees in pots contributed by Sir Carl Meyer, the King's Acre Nurseries, Limited, Jas. Vert and Sons and W. Seabrook and Sons; luscious-looking Strawberries from Laxton's, with Melons the equals of which are much too rarely seen at shows in these days; and superb vegetables, arranged with artistic skill to make a harmonious group, amid beautiful Sweet Peas, from Sutton and Sons.

Rosarians represented included the Rev. J. H. Pemberton, who staged several varieties of his own raising; Laxton Brothers, shewing one sort only, the exquisite single Pink Delight; R. Harkness and Co., who staged a varied group; Wood and Ingram, who had also numerous varieties; A. J. and A. Allen, who had many grand flowers; J. Burrell and Co., who worthily upheld the town of Cambridge; B. R. Cant and Co., who were in grand form; Daniels Brothers, who added herbaceous flowers to their Roses; A. Dickson and Sons and A. Edwards. Superb Sweet Peas came from A. Ireland and Hitchcock, Sutton and Son, Dobbe and Co., E. Webb and Son, R. Bolton and Alex. Dickson and Sons.

Carnations, Border, Tree and Malmaison, were staged by Allwood Brothers (who, of course, remembered to bring some Allwood Pink to cheer up their relatives), K. Luxford and Co. and H. Lakeman. Among those who sent hardy flowers or plants or both were R. H. Bath, Limited, Bakers, the Chalkhill Nurseries, John Forbes, Limited, R. C. Notcutt and R. Wallace and Co. W. Artindale and Son brought a pleasant change in the form of a small collection of fine Violas, while I. House and Son shewed a collection of flowers of perennial Scabiouses.

There were a few competitive classes, which although they did not, speaking generally, bring as many exhibitors as might have been expected, were magnificent in respect of the quality throughout and of splendid arrangement in most instances. J. Cypher and Sons and W. A. Holmes competed in the group of miscellaneous plants and were placed as named. In each instance the plants were the same and were disposed in precisely the manner with which visitors to the leading provincial shows have become familiar with during the past few years, and the thought

occurs that it is time that a material change of design was made. J. Cypher and Sons led with a collection of Orchids, excellent in all respects. Blackmore and Langdon were not assailed in the classes for *Delphiniums* and tuberous-rooted *Begonias*, and consequently annexed the premier award in each case. For a collection of hardy perennial plants and cut blooms the order of merit was Artindale and Son, Harkness and Co. and G. Gibson and Co. For a collection of cut sprays of Tree Carnations C. Engelmann assumed the lead over S. Low and Co., while in a similar class for Border varieties H. Lakeman was in the premier position. Collections of Sweet Peas were above the average of merit, and the prizes went to R. Bolton, E. W. King and Co. and J. Stevenson in the order given. The last and probably the finest class of all was for a collection of Roses, and the prizes were taken by T. Robinson, A. J. and A. Allen and W. and J. Brown.

The final impression on leaving was that this was the finest horticultural show that the Royal Agricultural Society had had; that it was most admirably arranged for the convenience of the exhibitors and the comfort of the visiting public by Mr. Peter Blair; and that if it had been poor the steward, Sir Arthur Hazlerigg, Bart., would have made people think that it was fine by his geniality and prompt willingness to give assistance or advice. L.

A Sussex Flower Show

HAYWARDS HEATH is blessed with a particularly good railway connexion to many residential districts, so that fine trade exhibits may usually be found there. This year's Show, held on July 19, was no exception, exhibitors coming from as far afield as Wolverhampton. Messrs. Charlesworth won the President's Cup for the best trade exhibit for the third year in succession. It now becomes their property. Noteworthy Orchids in this exhibit included *Cattleya Dupresiana*, *C. Hesta*, *Odontoglossum Xanthina* (with bright lemon spots on a primrose ground, the nearest approach to yellow in this section), *Coelogyne burfordense* (*C. pandurata* × *C. aspera*), *Odontonia brugensis*, *Erides Ballantineanum*, *Laelo-Cattleya Phoebe magnifica*, the bright yellow sepalled *Lælia tenebrosa* Walton Grange Variety and the Reed-like Swamp Orchid, *Sobralia Colmanii*.

Perpetual Carnations were worthily shown by Messrs. Allwood. Varieties specially noteworthy included the gallant scarlet Edward Allwood, Jessie Allwood, the quaint rose and helio Eastern Maid, Wivelsheld Beauty and the Perpetual Malmaison Mrs. C. F. Raphael. Among a considerable display of Allwoodii the soft pink Maud was much admired.

A particularly fine exhibit of Sweet Peas came from Messrs. Sutton, all grown in their Reading trial ground and proving conclusively that with proper care and cultivation these flowers can be grown up to exhibition standard on almost any soil found in Britain, for the soil at Reading is naturally shallow, light and hungry. Particularly fine were their masses of Tangerine Sensation (a fine scarlet), Doris Usher, Barbara and Sutton's Black-seeded Cream. A smaller exhibit, but with wonderful flowers particularly bright and fresh in colour, was set up by Mr. H. T. Dixon, of Polegate. Rather invidious to select the best here but personal taste suggested Hebe, Fantasy, Annie Ireland, Jean Ireland, Giant Attraction and the nice crimson Charity.

Colonel S. R. Clarke had an attractive exhibit of uncommon shrubs, with plants of the glorious

new *Anemone glaucophylla*. Messrs. Cheals had alpine and herbaceous plants, Dahlias and, in the open air, some well shaped and clipped topiary. Messrs. James Box had herbaceous plants, including many Phloxes, *Eremurus Bungei*, *Lilium Henryi* and *Romneya*.

The rock and water garden carried out by Mr. E. Scaplehorn, of Lindfield, was quite ambitious. *Primula Littouiana* was an attraction in this exhibit. It is surprising how many keen amateurs still seem not to know it. In a good bank of herbaceous plants, that best of Rudbeckias, *R. maxima*, was notable, while the Phloxes also were good.

Mr. Frank Woollard, of Brighton, had a bright display of Roses and quite a collection of small fruits. Messrs. Bunyard brought from Maidstone some good Roses, including the popular Golden Emblem; also herbaceous plants in some variety, including *Liliums Auratum* and *testaceum*.

In the competitive classes popular interest always largely focusses at this Show upon the table decoration class, for which Messrs. Charlesworth offer a very handsome cup additional to the prize money. These were judged by Mr. R. F. Felton, the well known Hanover Square florist, who afterwards explained the merits and demerits of the different arrangements to the competitors. Mrs. A. Swann, of Warminglid, was placed first with an arrangement of deep salmony apricot Carnations, *Croton* foliage and the variegated swords of *Glyceria aquatica* fol. var. The second prize winner, Mrs. A. E. Sales, showed what could be achieved with sprays of Dorothy Dennison Rose arranged with its own foliage. The premier award in the decorated fruit table class went to Mr. C. T. Allen, Warminglid (gardener, F. L. Tilling). The various kinds were good throughout, but there was nothing of outstanding excellence. Mr. F. H. Ansell, of Haywards

Heath, was first with a collection of hardy flowers, but the arrangement and setting up left much to be desired. Much better was the first prize exhibit in the class for twelve bunches of herbaceous flowers shewn by Mr. W. S. Poole, also of Hayward's Heath (gardener, J. W. Penfold). His best vases were probably *Lilium candidum*, *Phlox Antonin Mercie*, *Pentstemon George Home*, *Galega Her Majesty*, *Pentstemon barbatus* and *Salvia virgata*.

Fruit and vegetable classes throughout the Show were well filled. Other interesting classes included arrangements of hardy flowers in baskets and, for the school children, named collections of wild flowers.

ANSWERS TO CORRESPONDENTS

FLOWER GARDEN.

LAVENDER UNSATISFACTORY ("Shadow").—This is one of the troubles, vaguely classed as "Wilts," of which the cause is unknown, but in this case it is very probable that it is the result of very trying conditions of temperature. The colour of the damaged tissue is due to the collection of a blue pigment in the epidermal cells. The nodes survive longer because they are more fleshy and also because they can, to some extent, draw on the supplies of water in the leaves. This trouble is not likely to constantly recur.

LILIUM CROCEUM UNSATISFACTORY (K. D.).—The Lilies seem to be affected with the well known Lily disease, though *Lilium croceum* is not often so affected. It is probably placed where cold winds and spring frosts reach it, and this has weakened it and laid it open to the attacks of the fungus *Botrytis parasitica* which is the cause of this disease. Remove diseased plants and destroy them, also collect and burn diseased foliage. It is advisable not to plant fresh stock in infected beds.

NAME OF PLANTS.—J. M. C.—Rose Lady Pirie. —B. B. P.—*Ulmus major*. —M. S. S.—Banbury. —*Phacelia tanacetifolia*. —J. R.—1, *Dipsacus sylvestris*, "Wild Teasel". 2, *Amorpha fruticosa* (shrub), "False Indigo."

"WINDOLITE"

consists of a transparent composition reinforced with fine wire, from which

ROSE PROTECTORS

can be made at home in a few minutes at the cost of a few pennies only.

Take a rectangular piece of "Windolite" 12 in. by 6 in. (or according to size of protector required). Cut notch $\frac{1}{2}$ in. deep in centre of one of longer sides. Bend "Windolite" into conical or funnel shape the notch coming at apex to allow overlap. Fasten in this position by sewing or with "Windolite" solution. If desired the corners may be cut off with ordinary scissors.

"Windolite" being practically unbreakable has many other uses in the garden, taking the place of glass to make featherweight lights for frames and pits, or it can be made up without skilled labour into hand-lights and cloches of any shape or size. Also largely used for POULTRY and all OUT HOUSES. If your local dealer does not stock we will send you length from one yard upwards, carriage paid, on receipt of remittance.

Width - 23 in. 27 in. 31 in. 35 in. 39 in.
Prices 4/11 5/8 6/5 7/2 7/1

Also made in Double and Triple strengths, clear or in any colour.

"Windolite" solution 1/6 per 2-oz. bottle, post free.

Various uses are demonstrated in our showrooms where we are always glad to receive calls.

LETHORION

IMPROVED VAPOUR CONE

Registered Trade Mark 6295.

Fumigato

Introduced 1885.

NOTHING yet introduced has surpassed this valuable method of Fumigating Greenhouses. It combines economy with efficiency in every way, and is certain death to all pests, without any injury to vegetation!

Only a match required for starting it! Full directions for use on each Cone.

Nicotine is the effective agent in this Fumigator!

Prices.—No. 1, for Frames and "Lean to's" up to 1,000 cubic ft., 10d. each; No. 2, for Small Greenhouses up to 1,500 cubic ft., 1/3 each; No. 3, for general use in Large Greenhouses from 2,000 to 2,500 cubic ft., 1/9 each

FOWLER'S LAWN SAND

Established in 1875.

For destroying Daisies, Dandelions, Plantains, Ribbed Grass, Thistles and other weeds on Lawns, Croquet Ground, Bowling Greens, Parks, etc., at the same time acting as fertiliser and improving the growth and colour of the grass.

Many preparations are on the market under this name, but no article differs so much in value. FOWLER'S LAWN SAND has exceeded all others in money's worth generally.

TO BE HAD FROM THE TRADE GENERALLY.

Prices.—Tins, 16, 3/6, 5/6; Bags, 28lbs. 10/6, 56lbs. 19/6, 112lbs. 35/6.

LILIES FOR GARDEN AND WOODLAND

Everyone admires Lilies. Popularly supposed to be of difficult culture, many species are quite as easy to grow as Stocks or Asters for example.

JUST at this season, when so many Lilies blow, it may be well briefly to consider the requirements of some of the commoner species. Where provided with good rich soil and partial shade, conditions which they like exceedingly, so that the rich soil be not gross, the beautiful Madonna Lily, *Lilium candidum*, will yet be in flower. A very few weeks, however, will suffice to ripen off the bulbs, and before the month is out the planting season for this species will be upon us. The early ripening of *L. candidum* is somewhat of a nuisance, since it may not be planted at the season when herbaceous borders are remade. The nuisance is, however, mitigated by the fact that, once established, it is best left undisturbed for a number of years, and may be left *in situ* during two or three successive remakings and replantings of the border.

Most Lilies in the climate of Southern England like some shade or screen from the heat of the midday sun, a possible exception being the Tiger Lily, *L. tigrinum*. Shade is more especially necessary, however, for the stem-rooting Lilies, such as *L. auratum*, *L. speciosum* and *L. Henryi*, which do best planted where their stems can rise through light shade, between Rhododendrons or Azaleas, for instance, which are especially suitable in that they can always be lifted and replanted further apart when they become too close together to give the Lilies breathing room.

All the *Auratum* Lilies are beautiful, but the most vigorous grower is probably *L. a. platyphyllum* and the most striking *L. a. rubro-vittatum* with a deep crimson band to each petal. Of the varieties of *L. speciosum*—or *laucifolium* as it is often called in catalogues—the best are album

Krætzeri, a magnificent white; *Melpomene* and *magnificum*, two fine crimson spotted sorts; and *roseum*, less handsome, but plentiful—consequently cheap—and a vigorous grower.

Similar in shape to the *speciosum* group is the rich orange *L. Henryi*, which is, however, of bigger habit and more readily acclimatised. Indeed, it will succeed quite well in any good herbaceous-

border. The beautiful salmon buff hybrid Nankeen Lily, *L. testaceum*, is another excellent Lily for the herbaceous border, where its dignified carriage and uncommon colouring make it unique. It is equally valuable for thin woodland planting, which, indeed, suits practically every species.

Lilies like a soil which, while never suffering from want of moisture, never becomes in the least waterlogged. An exception is the Panther Lily, *L. pardalinum*, a handsome species attaining under favourable conditions giant stature—7ft. to 8ft.—with orange flowers like a giant "Turn-again-gentleman," more or less spotted with black. This fine Lily has recently been largely used for hybridisation, notably by Messrs. Amos Perry of Enfield, and some very fine hybrids, all featuring in greater or less degree the parent, have recently been exhibited.

No garden Lily is better known, probably, than the Tiger Lily, yet even this is not always grown as well as it should be. Some light-growing screen to shade its roots from the scorching rays of mid-summer sun is a great help. Many Lilies increase not only by offsets or from seed, but by means of bulbules formed up the stem, one in the axil of each leaf and which often emit roots even while growing on the parent plant. With many Lilies this is a phenomenon more frequent in some seasons than in others and partial at all times, but with the Tiger Lilies it may be relied upon as a constant happening, and these bulbules if removed and planted in shallow trenches in clean soil not devoid of humus will flower in two or at most three seasons. The best

MOST VIGOROUS OF AURATUM LILIES. *L. A. PLATYPHYLLUM.*
Admirable for thin woodland planting.

THE BEAUTIFUL NEW HYBRID MARTAGON LILY, MRS. BACKHOUSE.

THE MADONNA LILY, *L. CANDIDUM*.

single forms of the Tiger Lily are called *L. t. Fortunei* and *L. t. splendens* respectively. *Lilium tigrinum flore pleno* is the beautiful double form much admired by many who have no love for double-flowered forms in general.

Among Lilies unsuitable for the herbaceous border but admirable in thin woodland planting protected in some way from draughts are *L. giganteum*, which some seasons does well in the wild garden at Wisley, *L. regale*, the related *L. sulphureum* and the hybrid *L. sulphurgale*. The "Turn-again-gentlemen," as villagers often call the fragrant Turk's Cap Lily, *L. Martagon*, also shews to greatest advantage in semi-shade, but it is an accommodating plant, and is often seen to grow and to increase in the herbaceous border. The beautiful pure white form is especially attractive. Somewhat similar in appearance but larger in blossom and more vivid in colouring are the Scarlet Turk's Cap, *L. chalcedonicum*, and the golden Martagon, *L. Hansonii*. These choice Lilies also like shade from midday sun.

That invaluable forcing Lily, *L. longiflorum*, is of little use outdoors, but an alpine form of the little-known and tender *Lilium philippinense*, *L. p. formosanum*, bids fair to be an excellent and hardy white trumpet Lily. Bulbs received this spring under this name from India which had unfortunately "sweated" somewhat in transit, have not so far shown up, but as it comes readily and grows rapidly from seed in this country, it should not long remain scarce.

Lilium croceum, the beautiful Orange Lily of cottage gardens, which will flourish in any well tilled border or even under thin grass in old orchards, a situation in which it is seen to perfection, has, for some unexplained reason, become scarce of late years.

Beautiful among low-growing American plants in thin woodland is the fragrant *Lilium rubellum*, a dwarf Lily which bears rosy pink blossoms towards the end of May.

One of the most beautiful of Lilies of the herbaceous border is saddled with a frightful name—*L. monadelphum Szovitzianum*. This was well illustrated in *THE GARDEN*, October 15, 1921, page 513. In colour it is straw yellow, spotted black.

Lilium Thunbergianum, also known as *elegans*, is a very dwarf species which, like *L. croceum*, holds its cup-shaped blossoms erect. *Sanguineum* is the form most commonly seen; its rather brick-red flowers are spotted black, but there are others yet more beautiful. *Van Houttei* has larger flowers of a rich crimson hue; *atrosanguineum* deep red blooms, black spotted; *alutaceum*, bright apricot flowers, also black spotted; and the still rare Orange Queen has large bright orange flowers, usually, on established bulbs, in threes.

Another free-flowering, easy and early species is *L. umbellatum*, which attains a height of 2ft. or so. The commoner forms of this variable species are *grandiflorum*, *Sappho*, *erectum* and *incomparabile*, the first two light orange, while the last-named is a good rich crimson. *Erectum* has reddish flowers, flushed orange; and the later-flowering and admirable *Diadem*, bright crimson blossoms with a central yellow stripe to each petal, the finest and, alas! the dearest of the group.

Like a small Turk's Cap, *Lilium pyrenaicum* is yet another early-flowering Lily with clear yellow flowers, spotted black. Strongly scented, it is of the easiest culture.

The general requirements of this noble family of plants may be briefly summarised as follows: Partial shade, good drainage, a sufficiency of moisture in the growing season (in the air as well as in the soil), shelter from cold draughts, soil with an abundance of humus but free from any undecomposed manurial matter, and clean porous material immediately beneath and around the bulbs. Moisture in the air is best obtained by surrounding vegetation which tends to retain the evaporation which always follows copious watering around the plants. Shelter from draughts is often difficult to arrange, but very necessary. In woodland Bamboos are often planted to provide this, and if encroaching varieties, such as *Arundinaria japonica* (*Bambusa Metaké*) are avoided, are excellent for the purpose.

Quite spent horse manure, peat and well rotted leafsoil are suitable ingredients for providing humus, and are also admirably suited to the American plants of various sorts, especially *Rhododendrons*, with which Lilies are most happily associated. The best medium with which to surround the bulbs to keep them free from possibly harmful bacteria in the soil is coarse silver sand. Dusting the bulbs before planting with flowers of sulphur is supposed to assist in this, and is often done, but the writer would rather express no decided opinion upon its efficacy.

Most Lilies are obtainable from about October, but imported bulbs of *auratum* and *speciosum* seldom arrive before January. The shorter the period that the bulbs remain out of the ground the better for their ultimate well-being. For this reason the first arrivals almost always do best. It is wise, then, to order early—as soon as the price lists come to hand, in fact—and to plant the bulbs immediately upon receipt.

NOTABLE HARDY GERANIUMS

For Border and Woodland.

THE Cranesbills have many good qualities, apart from their individual beauty, one of these being the habit common to the majority, of blossoming in full summer when border and rock garden are not so gay as they were, and another is their easy-going temperament and adaptability to all manner of soils and situations. Most of them are sun-lovers, delighting in a free, warm soil, but there are some which appreciate shade and a cooler medium. Those which produce seed, and few do not, are easily raised from outdoor sowings, and they are, as a race, almost immune from pests and disease.

Here, as the heading suggests, I shall confine my remarks to those of the larger Geraniums

are easy-doers almost anywhere, and they hybridise so freely that the garden will soon be peopled with their pretty offspring in various shades of soft, chalky pink, veined and plain. So vigorous are these seedlings in suitable soil that they will naturalise freely in the herbage of open woodland and maintain a succession of flowers from June to November.

G. anemonæfolium, a Madeiran, which comes into flower about midsummer, is one of the most remarkable and beautiful of its race. The broad, glossy and deeply divided leaves are borne on rigid stems that spring from the crown of a short, stout stem, and from the centre of this fan-palm arrangement rise the equally stiff flower-stalks. These are beautifully furred with iridescent hairs,

of shrubbery where it can come up and take care of itself year by year. Well grown specimens will go up to 2ft. high, and the branching stems and large leaves assume a brilliant blood red tint before the plant seeds and dies.

Of *G. sanguineum* one need say little. It is so splendid a thing in the midsummer rock garden, and on its own limestone cliffs, that it is known and admired by everyone, even by those whose perception of colour is such an uncomfortable possession that they must affect a wry face at the faint suggestion of blue which may possibly permeate the gorgeous crimson of the Bloody Cranesbill. There are, of course, several forms of *G. sanguineum*—local types—and if I am not much mistaken, the *G. nepalense* usually sent out by the trade is none other than one of these, and a very fine one, too. Then we have the admirable white sanguineum, much larger in growth than our native and doubtless an albino sport from a Continental form, albeit a first-rate plant that will make a loose mound 18ins. high and 30ins. across. The charming little *G. lancastriense* is another of the sanguineum clan, very dainty and prostrate, with flowers of a soft rose

Of *G. nodosum* of gardens there appears to be some doubt, both as to description and origin; but to me it is an almost prostrate species, much after the habit of *lancastriense*, but rather larger, with little and round, deeply cut, grey-green leaves and crimson-purple flowers about an inch across. At any rate, this planting is one that makes a very cheerful note of colour from June onwards for many weeks. It seeds freely and does not indulge in indiscriminate unions with other species.

By no means to be despised is a good specimen of another native, *G. phæum*, with very dark, claret coloured flowers about the size of a shilling. This will make a bold, many branched plant up to 2ft. in height, and its bright green leaves are not infrequently marked with sepia blotches at the base of each of the large indentations. One form I gathered has, in addition to these blotches, similar variegations in bright rose and cream, all three colours being sometimes on the same leaf. *Geranium phæum* is a first-rate plant for thin woodland, but it appears to like a cool root run and enjoys nothing better to grow in than a heap of builder's rubbish. Though a sombre colour, there is something peculiarly fascinating about this Cranesbill, so much so that it is getting rare as a wild plant in many localities. There are *phæums* with flowers of a paler hue verging into pink and one with reflexed petals, but the almost black, large-flowered type with blossoms opening perfectly flat is, to me, the most attractive.

For a warm, sunny corner there is no more lovely species than *G. Traversii*, the home of which is New Zealand. The prevailing impression one gets of this Geranium is a silvery softness, for not only is the green of the ample foliage glossed over with a delicate film of silk, but this effect seems also to suffuse and cool to a more tender pink the exquisite flowers. *G. Traversii* is in habit and in all its parts the acme of good taste—a little difficult, perhaps, on some soils, but one of which a stock from offsets may easily be raised and kept in a frame over winter.

G. pratense is a useful old plant for massing in open woodland or shrubbery, and some of its varieties, notably the clear blues and whites, in singles and doubles, are not to be despised at the back of one's borders during July and later. Another well known kind, for a place nearer the front is *G. grandiflorum*, which bears at the tips of its 12in. stems pairs of very large single flowers which are a really good blue in the evening light, or the half shade that it enjoys. Like the foregoing, this is one of the later bloomers and one

LOVELY SOFT PINK, GERANIUM LANCASTRIENSE.

grown in this garden, and in doing so leave to someone else the task of unravelling the mysteries and nomenclature of the remainder which crowd the pages of some books and catalogues in such bewildering array.

G. atlanticum may be given first place because it is, with us, generally the first to flower. This species, which hails from the Atlas Mountains, makes a dense carpet of finely-cut leaves with a close resemblance to those of some Anemone, and from this green setting rise the rft. flower-stems in April or May. The blossoms are about an inch across, of a deep violet with faint veins of red. Shortly after the blooming season is over most of the foliage dies away until autumn, when the new leaves appear. This has proved a "pernickety" plant in some situations and one that takes a considerable time to get established, but this difficulty, I rather think, would be less apparent if the moving were done as soon as the foliage dies away in summer. It seems to be perfectly hardy.

The fine rose of *G. Endressii* is usually the next to appear, this being followed by the more silvery and reticulated pink of *striatum*. Both of these

and they branch into several heads which produce at their tips pairs of flowers in a charming crimson-pink, satiny of texture and deepening to a lustrous ruby eye. A succession of these delightful flowers is kept up until autumn, when the plant begins to make new leaves, and these, pushed out of the crown-like fronds of male fern in spring, continue growing throughout the winter so long as the weather remains open. *G. anemonæfolium* seeds freely, and the little plants come up in all kinds of unexpected places. With us it prospers in thin woodland and many other situations, but it seems to enjoy a cool, yet well drained, soil, and shelter from the noonday sun is advisable. In windy situations the head is liable to be broken off, and though *G. anemonæfolium* will stand 15° to 20° of dry frost, it is liable to perish when melting snow suddenly freezes like it did last April.

The Madeiran Geranium is a true perennial and, allowing for family similarities, could hardly be more unlike *G. Loweii*, with which it has been confused by some. The latter is simply a much magnified Herb Robert, invariably biennial, and quite a pleasing plant for the woodland or border

that, although it increases by root division readily enough, is happiest when left quite alone in a mass. *G. grandiflorum* remains in flower for some weeks, which cannot be said of the rich violet-purple *G. ibericum*. This is, nevertheless, a rare old plant, and its copious and handsome foliage makes amends for a short flowering season by turning a brilliant colour in autumn.

The gorgeous *G. armenum*, which will grow to nearly 3ft. in height and cover a square yard or so with its many-branched stems in bold leaves and brilliant crimson flowers, is one of the most noteworthy of this handsome family. It must be admitted that there is a tinge of blue in the wonderful colour of the large flowers, especially as these are going off, but the shining jet of the eye and its radiating veins does more than remove the stigma of magenta which the ultra-sensitive would bestow upon this noble plant. *G. armenum* does not set seed here. It is increased by root

division and is the better for breaking up every three or four years.

With *G. Wallichianum* I must wind up my list. This is a very distinct, hardy species, a Himalayan, with an uncommon predilection for a cool, half-shaded corner where it has plenty of room to disport at will, among Ferns or other things, its long, trailing stems. *G. Wallichianum* is a variable plant in the colour of its large, flat, or saucer-shaped, blossoms, which are commonly a subdued rosy lilac centred with a bold zone of white. But the best form by a long way is Mr. E. C. Buxton's variety, in which the blossoms are a clear *Nemophila* blue and not at all unlike those of that pretty Californian. This species can be raised easily from seed sown in the open, and Mr. Buxton's blue comes remarkably true to colour; but to attain its full beauty this plant must have shade, at any rate from the midday sun.

North Wales.

A. T. JOHNSON.

THE ENGLISH PERGOLA

Its Design and Placing

It is usual nowadays to designate any partially covered way clothed with vegetation a pergola. Within this all-embracing term must be included the tunnel of "rustic" woodwork—horrible survival of the scrappy "kniek-knacky" ideas of a past generation—the iron-arched fruit pergola and the stately erection with Doric or Corinthian columns which

are obviously not intended to be smothered with creepers.

Of structures so elaborate as the last named there is no need here to speak, since the number of people in want of such is small and since the services of a qualified architect are obviously required to design them. Leaving the classic colonnade aside, flower pergola pillars may be

adequately constructed of stone, brick or wood. The material employed will depend to a considerable extent upon the architecture of the house with which they are to be associated, but in many cases the question of cost also will be important. A pergola constructed of wood and capable of withstanding wind and weather for a number of years will cost considerably less than one built of brick. Brickwork, moreover, is generally considerably cheaper than even the roughest masonry. Brick and stone have, of course, the advantage of practically absolute permanence.

Taken broadly, the pergola should be rather a link between architectural features than a feature in itself. Of two features connected one is usually the dwelling-house, the other may be a summer-house, a substantial seat, a rotunda giving a view of hill and valley, or an ornamental building of almost any sort. In the small garden or in grounds of rather less than medium size this will almost certainly be the case, but where space is ample the pergola may be a feature in itself, as when a semi-circular pergola forms an amphitheatre in a hillside or, backed by trees on slightly rising ground, is used to close a vista. Since the pergola is admirable to display climbing and Rambler Roses, it has become usual to introduce a pergola partially to bound the rose garden. The rose garden is hardly a recommendable feature to introduce in the immediate purlieus of the house, and it is correspondingly difficult to arrange a pergola in the desired position which shall have any justification as a connecting link. It may, in such case, be made more satisfactory as an independent feature by taking it round two adjacent sides of the rose garden. If the floor of such pergola can be arranged, without too great a sense of artificiality, at the height of one or two shallow (say 5in.) steps above the level of the rose garden, so much the better.

The "tunnel" pergola with both sides closely draped with vegetation is a justifiable expedient where a path has to be taken through a stretch of ground in which it is not feasible to provide other features of interest, but generally an erection entirely open between the columns on at least one side will be desirable. It will often happen that a pergola quite open between the columns on both sides may be improved by the addition of a narrow herbaceous border perhaps 4ft. wide on either side.

So much for the placing of the pergola! In its proportioning we are restricted in one direction by the fact that its height must be sufficient to allow comfortable walking when it is draped with climbers. This in practice means that it should be not less than 8ft. tall to the underside of the cross timbers. Another 6ins. is, indeed, desirable. It is, of course, possible to carry a brick or stone-piered pergola considerably higher than this minimum, but except in the case of very massive pillars (associated with a building on the grand

A SIMPLE WOODEN PERGOLA. WINTER ASPECT.

scale) it is not desirable so to do. Admitting then, as we must, that a pillar in stone about 8½ft. high and about 18ins. or 19ins. in diameter looks properly proportioned in a pergola, how are we to arrange our slender (6ins. by 6ins.) oak posts in a pergola the same height so that the

Whatever the material employed, it is important in a squared pergola—the arched fruit pergola is really a thing apart—that the timbers should project beyond the piers on either side to a suitable distance which will vary considerably according to the width and proportioning of the pergola

quite a different proposition, but providing the slope is not too severe, it may be made very beautiful and interesting. The main points to be borne in mind are:

(1) That as in all terracing, the general lie of the pergola floor (taken either altogether over or altogether under the separate flights of steps) should be concave, which, turned into practice, simply means that the flights of stairs should be longer and the level stretches be shorter at the upper end than at the lower.

(2) That to avoid the danger of pedestrians striking with their heads the cross-timbers, or rather to avoid all appearance of danger of such a happening, the flights of steps should be kept well back under the higher pillars. The appearance of additional height to the piers flanking these stairs, which would, of course, destroy the proportion, may be avoided by having the stairs somewhat less than the width of pergola, thus leaving the piers a base upon which to stand.

THE FRUIT PERGOLA.

The fruit pergola has a very real charm, and is at the same time eminently utilitarian. It is, therefore, a feature which might well be seen more frequently. The British, as a nation, are somewhat neglectful of the beauties of fruit trees in all forms, whether as more or less naturally grown or as trained to walls, fences or pergolas. Most fruit trees are worthy, from a purely decorative standpoint, of inclusion in the pleasure grounds, a fact which is now being realised to a greater extent than has been the case for several centuries. May the realisation grow! The fruit pergola in its simplest form consists of arches of hurdle-iron with galvanised wires strained between them upon which cordon trees may be trained. The training of fruit trees to a square framed pergola presents, however, little difficulty, and this is

AN ADMIRABLE FRUIT PERGOLA.

proportioning shall remain satisfactory? The answer is simply by a narrowing of the internal width of the pergola itself and by spacing the piers closer together in the length of the pergola also. It may incidentally be mentioned that the piers may be set further apart in the length of the pergola if the tops are disjoined so that the pergola resolves itself into a series of quite independent square-headed arches. Some ideas as to suitable proportionings should be obtained from the annexed diagrams, but it must be borne in mind that the character and finish of the material employed has much to do with the apparent proportioning as we see it. A plain, smooth surface of dressed stone, for example, seems much wider than one of narrowly coursed but otherwise undressed stone with play of light and shade upon its surface.

itself. Many a satisfactory building owes its charm almost entirely to a bold roof-cornice or adequately overhanging eaves. The projecting cross pieces of the pergola are, though not continuous, in effect the roof-cornice of the pergola, and their proportioning is equally important. In case of doubt it is better to leave them a little overlong—they are more easily shortened than lengthened and in any event as vegetation more completely smotheres the pergola, the overhang will appear to get "smaller by degrees and beautifully less."

THE PERGOLA ON SLOPING GROUND.

The pergola running along the hillside presents no possible difficulty. It is merely a question of terracing below it and either terracing or contouring above to obtain delightful results. The pergola running up and down hill is, however,

Plan of a pergola "returned" and made symmetrical to form a feature in itself.

the natural form where wood is employed in the construction. There is no need to confine the planting of such a pergola to Apples and Pears. It may be diversified by the use of Loganberries and other hybrid Brambles, Blackberries and—where birds are not too troublesome—Red and White Currants.

FORTHCOMING EVENTS.

August 7.—Drayton Horticultural Society's Annual Show. Chippenham and District Horticultural Society's Annual Show. Lichfield Horticultural Society's Annual Show.

August 8.—Leicester Abbey Park Flower Show (two days).

August 9.—Royal Horticultural Society's Fortnightly Meeting. East Anglian Horticultural Society's Meeting.

August 10.—Yorkshire County Flower Show at Huddersfield. Cheshire County Flower Show at Stockport.

August 11.—Paisley Florists' Society's Meeting.

August 12.—Ringwood Horticultural Society's Meeting.

A wooden pergola in end and side elevation showing suitable proportioning; one in narrow coursed stone (undressed); and a series of disconnected wooden pergola arches.

LAVENDERS & SWEET PEAS AT VINCENT SQUARE

ALTHOUGH it was not a large Show, there was a pleasant variety of plants and flowers at the R.H.S. Hall on July 25 last. The new plants were perhaps the most interesting, and in addition to those described below, there were others of more than passing interest. A set of splendid Cannas was submitted by Mr. H. J. Jones, and these included J. B. Van der Schoot, bearing large yellow flowers freely spotted with vermilion, and Ami Max Kolb, of gorgeous scarlet-crimson colour. Messrs. Carter and Co. brought a good strain of *Antirrhinum* and *Godetia*, which are to be tried at Wisley. Mrs. M. V. Charrington, How Green, Hever, had a most interesting little collection of seedling Lavenders which she has raised, and several of them are of distinct garden value. We understand that these were to be seen later by the Scientific Committee with the view to a certificate of appreciation being awarded.

In the hall Messrs. Robert Veitch and Son had flowering sprays of such "Riviera shrubs" as *Plagianthus* Lyall (bearing beautiful white flowers), the deep scarlet shrubby *Pentstemon cordifolius*, and the Giant Honeysuckle, *Lonicera Hildebrandiana*. Another interesting and rather uncommon Honeysuckle was the plant of the golden variegated variety shown by Messrs. L. R. Russell, Limited, who also had a fine plant of *Erythrina Crista-galli* (the Brazilian Coral Tree), bearing plenty of its large pea-shaped, deep scarlet coloured flowers. This shrubby plant is

nearly hardy and may be grown in many gardens if it can be planted at the foot of a warm wall and the roots covered with broken coke for the winter. On the approach of spring the stems should be cut down close to the root-stock. In the same group there was a large standard, double-flowered Pomegranate. The flattish, pale rose coloured flowers were very interesting, but they are hidden away among the branches and do not show themselves so well as do the single flowers. Well berried branches of *Rhamnus Alaternus* were to be seen in the exhibit of Messrs. J. Cheal and Sons. The genus has no floral beauty, but it includes in *R. Purshiana* the low tree that supplies the cascara of commerce. An allied bush, *Paliurus aculeatus* (one of the Christ's Thorns), was shown by Mr. G. Reuthe, who also had the latest-flowering *Rhododendrons*.

Sweet Peas were splendidly shown by Messrs. Sutton and Sons, who were awarded the coveted gold medal. The many beautiful pink varieties held most attention, and these were Mrs. A. Hitchcock, Frilled Beauty, Picture, Giant Attraction and Doris Usher, though other shades were represented by equally well grown flowers which Messrs. Sutton and Sons always arrange so charmingly. In addition they had lovely sorts of annual *Scabious* and *Dianthus*. Excellent Sweet Peas were also staged by Mr. J. Stevenson, La France is a desirable bluish pink variety and, with Royal Scot, was quite the best of the standard sorts. Of several seedlings on view we were impressed with Poppy, which is almost

the colour of the cornfield Poppy and said to be quite sunproof; Wild Rose, charming shades of rose pink; and Cynthia, a most delightful soft lavender.

Carnations were very fresh and good, and besides Messrs. Allwood's large collection and Messrs. Stuart Low's, which included a quantity of their large White Pearl, there was a new variety called Mrs. G. R. Groom, shown in masses by Messrs. J. B. Groom and Son. It is said to be a cross between a Malmaison and a Perpetual, also that it is just as valuable for the border as for pot cultivation. The colour is a peculiar shade of salmon rose, and it is pleasantly fragrant. A very good collection of Border Carnations, with a few spikes of Gladioli, were set up by Messrs. Lowe and Gibson, who also had a fascinating vase of *Picotees*.

Roses were freely shown by several trade growers, but these did not include any new variety of merit, except the sweet red Henry Nevard and the pink Mrs. Alfred West in the collection of Messrs. F. Cant and Co., though Messrs. G. Bunyard and Co. had beautiful blooms, especially of the yellow shades. The most striking were Golden Emblem, Margaret Dickson Hamill and Christine, while the bowls of the single sorts Sheila Wilson and Isobel were delightful. Messrs. Bunyard also had some dishes and a few branches of culinary Cherries, but they hope another time to have a larger collection so as to illustrate the various types. The French sort, Triaux, was of splendid appearance.

FANCY BORDER CARNATION JESSIE MURRAY.

NEW SULPHUR YELLOW DELPHINIUM NYMPH.

NEW AND RARE PLANTS.

Campanula R. B. Loder.—A good pan of this graceful little Campanula was shown. The dark blue flowers are "doubled"—there are two corollas set hose-in-hose fashion. Its general appearance suggests *C. pusilla* and *C. rotundifolia* fl.-pl. parentage. Award of merit to Mr. M. Prichard.

Campanula Zoysii.—Although this charming little alpine was introduced from the Austrian Alps in 1896, it is not often seen in cultivation. The pale blue flowers have long tubular corollas with five triangular lobes which almost meet. Although it is quite a tiny plant, it flowers profusely and increases freely in the mooraine. Shown by Mr. M. Prichard.

Carnation Jessie Murray.—This is a very beautiful fancy Border Carnation. The large blooms are of perfect shape, and it is said to be very free flowering. The milk-white ground colour is lightly flaked with lavender, and the flowers are pleasantly fragrant. Award of merit to Messrs. Lowe and Gibson.

Delphinium Nymph.—A handsome spike of very uncommon appearance. It is exceedingly well furnished with large, shapely flowers of sulphur yellow colour, which is relieved by brighter stamens. Award of merit to Mr. M. Prichard.

Eryngium prostratum.—A very fascinating little plant only a few inches high. It forms rosettes of pale green foliage, from which rise the short-stemmed blue flower heads surrounded by green-tipped white bracts. This pretty little Sea Holly does not differ greatly, if at all, from *E. Cavanillesii*. Award of merit to Mr. Amos Perry.

Disa Julia A. Stuckey.—This genus of beautiful, nearly hardy Orchids are now, unfortunately, rarely seen; but when well grown, as was the case with this new variety, the flowers are most handsome. *Disa grandiflora*, which was one of the parents, is sometimes known as the "Flower of the Gods"; the other parent is *D. italia*. The two lateral sepals are of glowing rose colour, while the hooded, lateral sepal is lightly flushed with rose and beautifully veined. Award of merit to Messrs. Flory and Black.

Gladiolus primulinus Firecrest.—In this primulinus hybrid the individual blooms are well disposed on the spike. The velvety scarlet crimson flowers have plenty of substance, and the three outer segments are flaked with maroon. It should be exceedingly effective either for the garden or for cut flower. Our only objection to this variety is perhaps a sentimental one, but we do think it a pity that so many of the new primulinus hybrids which find favour have entirely lost the coy charm of the species. The primulinus hybrids, in our view, should not be mere miniatures of such varieties as Halley or America. Award of merit to Major George Churcher.

Kniphofia Rouge et Souffre.—Very few of the visitors who saw this handsome "Red-hot Poker" agreed with the Committee in "passing" it, for it is a really gorgeous variety. The rosin heads are borne on tall, stout stems, and the vermilion flushed buds at the upper part contrast finely with the pure yellow flowers below. Shown by Mr. M. Prichard.

Lavender Lady Violet.—This well variegated Lavender should be very welcome to lovers of variegated foliage. A compact little bush was exhibited, and it appears to be of neat habit. It was not in flower, but the leaves retain the agreeable scent of the type. Award of merit to Mrs. M. V. Charrington.

QUAINTEST OF BELL FLOWERS, CAMPANULA ZOYSII.

RICH PURPLISH-BLUE, CAMPANULA R. B. LODER.

Lavender Prudence.—The flowers are larger than those of the common Lavender and they are borne in more compact spikes. The colour, which is rather paler than the type, may be termed a glowing silvery lavender. Award of merit to Mrs. M. V. Charrington.

Odontoglossum Tagus.—A robust spike of large flowers was shown. The markings are of dull chocolate colour, and the lip is lightly flushed with pink. Award of merit to Mr. R. Gerrish.

O. Topaz.—This Orchid is somewhat similar to the above, but the flowers are larger. The marbling is a warm claret maroon on ivory-white ground, and the crest is golden. Award of merit to Mr. R. Gerrish.

Pyrus Aucuparia moravica.—The Moravian Mountain Ash is also named *Pyrus dulcis*, no doubt because the fruit is eaten in Germany and

Austria. The pale orange coloured fruits are larger than those of the common Mountain Ash, and the finely cut leaves are more graceful. From a foliage point of view it is one of the handsomest of the Rowan trees. Award of merit to Messrs. R. Veitch and Son.

Lilium sulphurgale.—This garden hybrid which, as the name indicates, is derived from *L. sulphureum* and *L. regale*, is tall, robust, well furnished with relatively small, narrow leaves and surmounted by plenty of flowers. The buds are bronzy purple, and this color is retained on the petals. The flowers are much shorter than those of *L. sulphureum* and lack the yellow tone, but are exceedingly pleasant to look upon. Many people prefer the purity of tone of *L. regale* but this is a matter of taste. Award of merit to Mr. Amos Perry and Messrs. Wallace and Co.

SOME EXCELLENT ANNUALS

Being notes of a recent visit to the trials of annuals at Messrs. Sutton's seed trial grounds, Reading.

THE world-famous seed-house of Sutton deserves well of all gardeners, amateur and professional, not only because of the super-excellence of their strains of vegetable and flower seeds, but because of the value of the trials which are held each year on their well known trial grounds at Reading. Anyone interested is gladly shewn the trials and furnished with all the information he, or she, may desire.

The large demonstration plots, from which, incidentally, seed is gathered, form the glowing masses of colour which are so notable a feature when viewed from passing trains on the G.W.R. main line, but the actual trials raised from the bulk of seeds from which customers were supplied in the spring are the most interesting feature. Trueness to type may thus readily be observed, for the trials are not "rogued." The quality of the mixtures supplied may also be appreciated.

Of the high quality of the strains under trial there can be no question. Taking the annuals as a whole, the percentage of "rogues" is quite negligible. Such satisfactory results can only be obtained by the utmost care on the seed grounds to prevent cross-pollination, and by periodical re-selection in addition.

The selection of varieties is always to a large extent a matter of personal taste, but the following were some of those which made the most favourable impression on the writer. It must, however, be mentioned that the day was dull after a wet night, and sun-loving flowers, like the *Eschscholtzias* and *Sweet Sultans*, shewed to small advantage on that account.

Of the forms of the Field Poppy, *Papaver Rhoeas*, the double Shirleys are perhaps most noteworthy, though, owing to the conditions of culture—the seeds are sown thinly, but the seedlings go unthinned—they have not the size which, under good cultivation, the same strains shew in our gardens. The single sorts, however, are very beautiful, especially the selected "pink and apricot" shades. The "single scarlet," too, somewhat similar in colour to the field Poppy, but a thought brighter and with a white basal cross instead of the typical black one, would appeal to many. The "slate blue" shades of so-called Double Shirleys also have an attraction, even to those who, like the writer, appreciate most pure clear colour. Shirley Poppies these should not really be called, since they have not the pale base which is the "Shirley's" birthright.

The Opium Poppies, *P. somniferum*, make a less general appeal, but the best on view are perhaps Peony-flowered "mauve" and "creamy-white"—the latter of a pleasing greenish hue reminiscent of *Chrysanthemum Mme. E. Rogers*—and the "giant double chamois-rose." The crimson-scarlet, black blotched species, *Papaver umbrosum*, is very striking, and two other species, *P.P. glaucum* (Fulip Poppy) and *Pavonia*, also are noteworthy.

As all gardeners know, dull weather is all against the increasingly popular *Eschscholtzias*, but the splendid *Geisha*—crimson brown without, golden yellow within—is wonderfully beautiful even with its flowers close sheathed. Near-by, a row of the tiny "miniature primrose," surely one of the most delightful of miniatures, is absolutely smothered in blossom.

The *Clarkia* trials are noteworthy for absolute trueness to type and colour, but the individual flowers are, owing to the conditions under which

they are cultivated, not up to the standard easily attainable in gardens. The new stock of salmon-scarlet is of almost dazzling brightness and excellent in every way, but the old stock bearing this name is exceedingly beautiful and, moreover, more restful in colouring. It is to be hoped that the firm will not abandon it altogether in favour of the new one; there is room for both. The trial of "mixed *Clarkia*" was remarkable for the entire absence of the purplish shades which not so many years ago largely predominated.

Those who admire that large-growing, sub-shrubby Mallow, *Lavatera Olbia*, will wish to possess for their annual borders *Lavatera rosea splendens*, very similar to it in many ways, as well as the newer deep coloured form listed as *Loveliness*.

The Scotch Marigolds (*Calendula*) as they grow at Reading rival in size of blossom and colouring the "leggy" African Marigolds, while they are infinitely freer to flower. The glorious double forms, Orange King and Lemon Queen, are admirable and come very true to type, but the single Meteor, orange yellow with a primrose zone, probably makes an equally wide appeal. French Marigolds are largely represented, both in tall and dwarf strains. Two dwarf varieties are specially attractive—*Star of India*, with petals alternately bronze and gold, and *Queen of the Dwarfs*, crimson bronze, wire-edged with gold.

Among the *Godetias* the first to catch the eye must always be the brilliant magenta-toned crimson *Afterglow*, more crimson than, but almost as startling as, the *Rock Purslane*, *Calandrinia umbellata*, which, by the way, is readily raised from seed. This is a dwarf variety, the nearest to a counterpart in the tall section being *Scarlet Queen*, a little richer, a thought less brilliant in tone. The beautiful *Apple Blossom* is not so happily named as most of Messrs. Sutton's specialities. The larger portion of each flower truly is apple blossom colour, but the deep ruddy blotches which occupy almost half the petals give a weight of colouring inconsistent with the title. The double counterpart of this, also very lovely, is called *Double Beauty*. Another fine bicolor, but in deeper shades of colouring, rejoices in the name of *Rosy Morn*. Other really beautiful sorts here are *Lavender Gem* and *Double Rose*, this last having a decided hint of salmon in its colouring.

Of the annual Lupins much might be written did space permit, but since a selection must be made we will plump for Sutton's dwarf rich blue (*sub-carnosus*) and Sutton's dwarf yellow, the latter of a clear rich golden shade still wanting in the perennial herbaceous forms, as the best two varieties. *Hartwegii* azure blue and *mutabilis* cream and pink, which is very similar to the best types of pink perennial Lupins, must be placed *proximo accessit*, so near, indeed, that some good judges would no doubt prefer them. That quaint yellow-flowered species, *Lupinus Menziesii*, was also noted.

The popular *Gypsophila elegans* is much in evidence, not only the useful and ubiquitous white form, but the so-called crimson variety, of which the newly opened flowers are truly bluish crimson, but which in the mass gives a rich rose effect, and the yet showier variety called delicate pink. This is a real pink, not a blush.

Of the *Sweet Alyssums*, minimum is distinctly the most compact and best for edgings, though *Little Berrit*, of less prostrate growth, is also

excellent. Among the showy annual *Viscarias*, the very compact and rather late-flowering "dwarf carmine" is most attractive. Of the Virginian Stocks (not favourites), *Crimson King* seems best, though in the mass it gives little hint of crimson. Many who dislike or, at any rate, can find no use for the typical form of *Silene Armeria*, would like the new soft pink form.

The prostrate *Campions*, *Silene pendula*, are invaluable for spring bedding, as well as useful for summer flower. Very lovely and true to type is Sutton's "double salmon-pink," its only rival being the rather more compact "dwarf delicate pink." From these delicate pink shades we turn to the bright china-blue platters of *Nemophila insignis*. The other colours in this charming annual seem so inferior that one wonders they are still in commerce. It is rather surprising, however, that *Nemophila atonaria atrocœrulea*, an easy-going plant with flowers of *Phacelia* blue, is not more widely cultivated.

(To be continued)

THE CULTURE OF BEARDED IRISES

THOSE fellow-readers of THE GARDEN who have grown the old German Irises for years and been uniformly successful with them although they have never spared a thought as to their culture, will doubtless smile at my title. It is of course, true that in certain rather light, clean soils these plants will flower freely and the blossoms will be little out of character, even though the only attention they receive is lifting and dividing when they become excessively overcrowded.

Not everyone, however, has such natural soil, nor will the possessor of such find it of much avail should his plants unhappily become infected with rhizome-rot. To obtain the best results with these Irises, particularly as regards size of flower, the soil should not be over-light; it should, on account of the "rot" danger, contain a fair percentage of lime, but it should not contain any appreciable content of humus. Burnt earth, particularly if rather on the heavy side before burning, suits them admirably and may be used freely. Drainage should be free, the site where they are planted open to sun and air, and the root-stocks should at no time be buried to more than half their depth.

There seems no doubt that varieties which are shy to flower—and some of the newer ones are rather shy—flower best when planted in full sun and left to establish themselves for a year or so, but there is wide scope for systematic investigation as to the comparative requirements of the different sections. Personal experience would suggest that the squalens and variegata sections are more weatherproof than the stately pallidas and trojanas, for instance. The former appear to withstand with greater equanimity—if the word may be pardoned—summer heat and winter wet.

The same remark will apply with equal force to planting times. It is by no means clear which is, in fact, the best planting season—indeed, there are considerable differences of opinion on the question—but may not the fact be, after all, that different sections and, since so much inter-crossing has taken place, different varieties, even though somewhat similar in appearance, transplant best at separate seasons? Such an investigation might not be of much practical value, since the average gardener would scarcely care to plant half a dozen sorts of Iris at different seasons, but it would be interesting none the less. H. H.

THE TENT CATERPILLARS

A plague to fruit growers.

ONE of the most injurious of these tent dwellers is the handsome little caterpillar of the lackey moth. It happens that, in some years, our fruit trees, especially the Apples, are infested with these larvae; a single tree will support colonies, and in each colony there may be as many as two hundred individuals. It is difficult to do anything with them when they have once got well started on their raids, and the fruit trees often suffer enormously.

They have now stopped eating, however. They stopped three weeks ago, and the caterpillars left the communal home and sought suitable spots for pupating. Their cocoons are of yellow silk, mixed with caterpillar hairs and a yellow powder, and the occupants are now ready to emerge as moths. A few have already emerged, and their next and immediate step is to lay the foundations for the next generation.

The moths themselves are out of our reach; it is always a very difficult matter to trap and destroy winged insects; but what about the eggs? In this case, fortunately for us, the eggs are very easily found and as easily destroyed. The moth lays them in such a curious fashion and in such an exposed situation that many hundreds may, with a little trouble, be destroyed early this month. They are laid on the tiny apple twigs, not in little groups that might readily be overlooked, but in close-fitting circles round the twig. They are firmly glued together, but are not fastened to the twig itself, and if the latter is cut off with a pen-knife the bracelet of eggs may be gently twisted off without breaking it. Before you crush and destroy all the little bracelets you find put one under a magnifying glass and examine the neatly arranged eggs; they are covered with a sort of varnish that, no doubt, perfectly protects them from the weather during the winter, if they are lucky enough to escape the sharp eyes of the owner of the Apple tree and of the birds. It is possible that the moth owes its popular name to this varnish or lacquer, though a more generally accepted explanation is that it is due to the gay stripes and colours of the caterpillar's coat.

Of course, this remedy of destroying the eggs is useful only in small gardens and orchards. On a larger scale other remedies would have to be used, such as toxic sprays. Powdered white hellebore (freshly ground) may be mixed with water—say, 2½ lb. to 10 gallons of water; the spray must be very fine. These quantities make a strong solution, and very frequently a solution of 10 ozs. to 5 gallons is sufficiently powerful. Though hellebore is poisonous to animal life, it does not injure the trees, beyond discolouring the leaves, and, when dry, the powder may be sprayed off with clean water if desired. This is a remedy for the summertime, when the caterpillars are devouring the leaves. I do not think either this or a spray made of Paris green would have any effect on the eggs; they have been too well protected with the "varnish."

The services of insect-eating birds during the autumn and winter should be utilised to the utmost. In this connexion, probably, the tits are our best friends. During the nesting season, of course, all birds search out eggs and grubs and insects for their families, but the tits eat insects themselves as well. An excellent idea is to provide them with nest boxes. I believe they appreciate these for sleeping in during the very cold nights, and it is very probable that, in the spring, many birds will stick to these cosy homes instead of wandering away. M. H. CRAWFORD.

Lackey Moths, small plump-looking insects with an average wing expanse of 1½ ins.; colour pale ochre, the transverse line brownish.

Eggs of Lackey Moth laid around apple twigs in early August.

FLOWERS IN RAIN

BY GERTRUDE JEKYLL, V.M.H.

IT is interesting to see, when steady rain is falling, how differently various kinds of flowers take it. Hydrangeas are quite undaunted; Mulleins are wide open and enjoying themselves. Some tall old bushes of *Cistus cyprus* look as if they were bearing the bloom of quite something else, for instead of having the usual flat, open shape, the flowers hang like inverted cups. The tall *Eurotia Lamarekiana* is also heavily depressed, but only mechanically; one sees that it is but for the moment and that as soon as the heaviest of the wet is over, the overladen blooms will expand and rejoice. Some are nearly full open in spite of the downpour—great luminous cups of purest pale yellow. The low-growing *E. missouriensis* is wide open. All the *Campanulas* seem to be rainproof; none shows any signs of distress except *C. lactiflora*, and that again is only mechanical, the tops being broken down with weight. *Chrysanthemum maximum* is wide open; *Eryngium* and white Everlasting Pea are untouched. *Heleniums* and other flowers that shut down their petals at night have them half down. *Senecio artemisiaefolius*, that fine deep yellow border plant that is so strangely neglected, stands up bravely. The perennial Mullein, *Verbascum Chaixi*, is brilliant and more fully open than it ever is even in ordinarily cloudy or drizzly weather. The great cup and saucer Canterbury Bells get partly filled and then turn down to tip out their load of wet. It is amusing to watch an adventurous bee, one of the few that are about, trying flower after flower, and refusing any of the great bells that have a wet flooring; at last he reaches one that was protected by others above it, finds dry footing and disappears into its recesses.

But of all flowers in rain the Sweet Williams are the most deplorable. They have the appearance of being thoroughly soaked and miserably uncomfortable and as if they could never be quite dry again. They are close to the Raspberry cage and the Raspberries must be visited. The fruits are loaded with wet, and it is as if one ate quite a new kind that had quite three or four times its usual amount of juice. I can confidently recommend Raspberries and rain!

Anchusa hangs down, but only from the weight of wet, for a little shaking restores its poise. The rain runs down the Bamboo foliage and drops freely from the points, leaving all the surface wet, but if one turns a leaf over the raindrops run off without wetting it. I do not know whether it is the same with all, but of the Bamboos I have I find it impossible, short of rubbing it hard in, to wet the underside. But it is pretty to see the Lupins. Coming upon them in an interval in the downpour, every leaf holds a little crystal globe where the leaflets join, with many smaller ones all about. Here, again, the leaf surface does not seem to be wetted all over, as the crystal beads, sometimes singly and sometimes clustered, do not lose their globular form. Their size is in proportion to that of the leaf. In the large perennial *L. polyphyllus* the leaf-cup holds a globe over a quarter of an inch in diameter, while the smaller leaved Tree Lupins are gannet all over with tiny round crystals. *Erigerons* are certainly unhappy and look woefully bedraggled; the ray florets, though on plants of the best kinds, are for the time being thin and skimp. *Artemisia lactiflora* is thoroughly contented, in pleasant contrast to its shrivelled, withered appearance in the drought of last year. *Anthemis tinctoria* stands the wet well, but best of all is the triumphant appearance of the Snapdragons.

CORRESPONDENCE

ROSE KEW RAMBLER.

IN the issue of July 22, page 357, Rose Kew Rambler is referred to as suitable for "pergolas, archways and for similar purposes." To avoid disappointment to planters of this beautiful Rose

in the valley (500ft.) fell to 32.9 the night after the snowfall, so presumably there would have been several degrees of frost at that altitude.

As they enjoy wet situations and a heavy rainfall (we had 25ins. during last June and July and probably double this fall in the mountains), I should think they ought to succeed out of doors in the South of England.—LIONEL BAKER, *Groot Drakenstein, Cape of Good Hope.*

QUAINT CYCLAMEN SEED PODS.

I AM enclosing a photograph of a tuber of *Cyclamen neapolitanum* which should, I think, be of interest to readers. The tuber is 6ins. in diameter and was grown in deep loam soil in Hertfordshire. The picture shows what I consider to be an unusually fine lot of seeds. As will be seen, fibres are produced all over the surface of the tuber. This *Cyclamen* has been naturalised successfully in several localities in Britain.

This, perhaps the handsomest of hardy *Cyclamens*, has ivy-like foliage and relatively large flowers, produced in the autumn in varying shades of pink or pure white, spotted crimson at the base of each segment. It flowers best when not growing too luxuriantly, but is not at all shy to blossom under any reasonable conditions of culture. It will succeed in light shade or full sunshine.—H.

THE REMOVAL OF SPENT FLOWERS.

HOW often one sees in gardens dead flowers—especially Roses—left on the plants! I make a practice of removing all flowers when past their best. This work in some instances is a back-aching pastime, but I get my reward in the form of more flowers. Not only do spent flowers give the garden an untidy appearance, but they do not improve the health of the plants concerned. Suckers should also be removed. If every garden-lover would pay a little attention to this "cutting over," our gardens would present a more cheerful appearance.—L. H.

MUSSINI'S CATMINT.

A NOTE of mine concerning *Nepeta Mussini* which appeared in *THE GARDEN* last October gave rise to some enquiries among friends of mine as to its capabilities, and the outcome was the establishing of it in several gardens to which, previously, it had been a stranger. I know of no hardy herb half so accommodating, and be the season what it may, its flowering is never hindered. At the present time—thanks to the rain—plants are full of young shoots which spring from the base, and these if cut and planted in sandy soil quickly take root. One point worth remembering in propagating *Nepeta* is to prevent, if at all possible, flagging of the cuttings should the weather be hot and dry. Young plants as a rule give the finest spikes, though from old plants there is little dearth in numbers. The colour, a lavender or smoky blue, is very pleasing, and the blossoms continue in good state for many weeks. I have noticed in several establishments that *Nepeta Mussini* is being used as a fringe to borders in the vegetable domain as well as on shrubbery borders. This is

not a matter for surprise considering how rapidly young plants grow. Every little portion quickly strikes in soil of a sandy nature.—CLAREMONT.

BOX EDGINGS TO ROSE-BEDS.

SOMETIMES in old establishments one finds beds and borders edged with Box that gives evidence by its growth of having been planted many years. One such instance came under my notice recently, where beds of Roses surrounded by this primly kept shrub were in a very bad state through the ramification of the roots of the Box, which had simply sapped all the nutriment rightly belonging to the Roses. Comparatively few in these days permit Box to usurp ground rightly belonging to other plants, least of all Roses. In the case under notice the edging consisted of a wall of Box some 8ins. in height and 6ins. in width, and the roots had spread to such an extent that scarcely any Rose in the bed was free from them, and poverty of wood and insignificant flowers revealed all too plainly that the edging had taken complete possession. At its best Box cannot but be regarded as prim and stiff, and if left for years must eventually destroy plants in the immediate neighbourhood of its roots.—W. LINDERS LEA.

LILIES FROM SEED.

I HAVE read your article on "Raising Perennials from Seed" (*THE GARDEN*, July 1) with the greatest interest, especially as regards Lilies. In 1918 I sowed a packet of *Lilium regale* seed, obtained from Messrs. Thompson and Morgan, in a pot which was placed in a small cold greenhouse. For some reasons (chiefly woodlice, I believe) it was very difficult to raise anything in the house in question, and I thought myself lucky in getting two strong seedlings—this Lily then being priced at 10s. 6d. each by nurserymen. The two, in 5in. pots, suffered many things from repeated removals on our part, but triumphantly flowered in 1920, being then, still in their pots, in a small town garden, or backyard, in Pulleney Street, Bath. They then ripened seed, which I sowed immediately in a box. This, in its turn, travelled about with us, spent six months in Wales, where the seedlings grew rapidly, then a like period at Trowbridge and at Box in Wilts, both of which places they seemed to dislike, making little advance; finally they returned to Bath, were potted off, three in a 6in. pot, in rich, light soil of loam, leaf-mould and old hot-bed stuff, with a little Weston-super-Mare sand, and are now, to the number of about fifty, a picture of health. There is, of course, nothing particularly interesting in this history, but it shews that there is no difficulty in raising for oneself a fine stock of Lilies that, even now, would cost 5s. to 7s. 6d. each to buy. (It also shews, I think, that the nurserymen ask too much for Lilies in general.) No doubt the Lilies would have got on faster if I could have treated them in the right way, as described in your article, and left them undisturbed.

Some *Martagons* we found in our garden at Trowbridge ripened a lot of seed last summer, and this, sown in boxes, is also up and making second leaves, but does not seem quite so quick or so vigorous as *L. regale*. The worst thing about this most fascinating pursuit of Lily growing is that it is so hard to come by the seed in a fresh condition, or in any at all, for that matter. I hope some of your readers who grow Lilies will be kind enough to advertise their superfluous seed for sale this season!

It is a curious thing that the common *L. candidum*, seen so much more often than any other Lily, never seems to increase itself by seed. I never got a voluntary seedling from large beds

THE QUAINT TUBER AND SEEDS OF CYCLAMEN NEAPOLITANUM.

they should be acquainted with its habit of growth. No doubt, with a certain amount of persuasion and pruning, Kew Rambler could be induced to cover an arch or pergola, as the old (parent) plant is now 10ft. high. Rather, however, is it a husky "rambling" than a "climbing" Rose, more suitable for clothing a rustic fence, an open wooden fence or rough poles with spurred branches 5ft. to 7ft. or 8ft. in height. Pushing up vigorous young shoots from the base, the best treatment would appear to be the removal of the old stems to the base after flowering each year.

A cross between *Rosa Soulicana* and the popular *Hiawatha*, the individual flowers average 1½ins. in diameter. The centre of the flower is white with a broad band or edging of rich pink. Kew Rambler might easily be mistaken, as far as colour goes, for the artificial Roses sold on *Alexandra Day*. In addition to a pleasing fragrance, it has a very showy tuft or rosette of golden-tipped stamens an inch across. Another important characteristic is the substance and consequent lasting character of the flowers.—A. O.

THE LACHENALIA IN NATURE.

IT may be of interest to growers of *Lachenalia* in England to know of the severe conditions they have to put up with in their native haunts.

The best patch of these charming flowers I have seen is situated on the top of a small rounded peak at about 2,000ft. above sea-level. Here they grow in thousands and are comparatively undisturbed, except by baboons, which destroy a good many by pulling up the bulbs and scattering them about.

During the past week (the last week in June) this peak was thickly covered with snow for four days, just at the time when the plants are in full growth. This is no unusual occurrence, though the snow seldom lies for so long. The temperature

of it, and, for that matter, cannot recall having seen its seed—perhaps because I never looked for it! When one has a large garden it is so easy to divide things. It is only when a gardener goes under the harrow of repeated house-movings that he realises what working up stocks means, and begins to sit up and take an intelligent interest in economical production!—M. L. W.

[The nurseryman who grows his own Lilies has to employ hired labour and allow for rates, taxes, depreciation of frames and other items. Competition alone, would ensure cheaper prices were such feasible.—ED.]

IMPROVING VILLAGE GARDENS.

ON page 202 of your issue dated April 23, 1921, you published a review of the excellent work which has been accomplished at Old Warden, Bedfordshire, in the cottage gardens as a direct consequence of the competition instituted in 1903 by the late Colonel Frank Shuttleworth and maintained since his demise by Mrs. Campbell, whose residence is Old Warden Park. There was a compulsory break in the sequence in the war years of 1915, 1916 and 1917, and a second lapse came last year when, owing to the protracted drought, there were no crops upon which to adjudicate, very much to the regret of Mrs. Campbell.

The judging was done this year on July 17 and 18, when marks for every crop growing in rather more than forty cottage gardens were recorded on the recognised scale. The result brought no fewer than thirty-four successful cultivators, with a grand total of 4,012 marks. The prizes are at the rate of a penny a mark for every mark secured, with the reservation that no

do the judging. The keenest interest is displayed by every cottager in the village, and there is a proper, general appreciation of Mrs. Campbell's generosity in maintaining it.—HORACE J. WRIGHT.

FRAGRANCE IN THE ROSE.

READERS of THE GARDEN are indebted to the writer of the short article on page 341 on this subject. There is, unfortunately, too much pessimism rampant in regard to Roses which lack fragrance, and though scentless varieties only constitute a very small minority, some people apparently never seem to forget their shortcomings in this particular, and close their eyes to the other charms they possess of beauty and grace, in colour and form. It may be remembered at the time of the introduction of Frau Karl Druschki, with its peerless white blossoms, its lack of perfume was much commented upon, and on this account alone there were those who refused to grow it. Surely when so many Roses possess the subtle gift of sweetness we can afford to ignore the absence of it in so few otherwise charming sorts! After all, the proportion of Roses exempt from perfume is so small that we need not be despondent! The list of fragrant sorts published does not include all those valued because of their aroma by any means, but it is enough to show that no one need be without Roses that are both sweet and beautiful.—L. W.

BEARDED IRISES AND LUPINS.

SHOULD you care to reproduce the enclosed photograph of a piece of my garden I should be glad for you to do so. Very few people realise what a gorgeous display can be had in May and

ENGLISH IRISES

Collection growing.—The pleasures of anticipation.—A selection.—The wand of the rain.

AFTER a long interregnum I have this year again renewed my personal acquaintance with the English Iris, not that the garden has ever been wholly without any, for I have been carefully "growing on" a lovely deep rosy mauve seedling of my own; and for a short time I had a deep purple and a rich blue—both likewise home-raised—but these last two, alas! were victims of the war. They were all three *sels*. Last autumn the time seemed to have come when I might get a small collection for trial. I am always very keen on collection-growing. The pleasure of anticipation is still as green and virile within my breast as ever it was and coupled with this there is the mild but very real excitement of seeing if anything good will turn up among the unknown or the forgotten. I am always ready to be told of "good things," but as "stolen waters are sweet and bread eaten in secret is pleasant," so finding out for oneself which are the best among the flowers that have lent themselves to variation is sweet too. Therefore I am a confirmed grower of collections. Comparisons here, as Shakespeare says, are odorous, *not* as lesser men would have it, odious. They are the sweet smelling savour which seems to satisfy the natural bias of human nature to pick and choose.

Sometimes we get jars. The result of the trial is far from what we expected. The truth must be told that the English Irises were a most disappointing lot. There was not a single self-coloured variety among the twenty-five and, worse still, for the first time my choice mauve seedling had six broken or blotched blooms. I cannot honestly say that I cared very much for any one of the whole collection. Even the whites were tinged or striped with colour, and were poor things compared with the pure Mt. Blanc of other days. Every one was blotched or marked in some way. Have all English Irises become jazzers? Have they all discarded those beautiful self colours that I remember so well? Tell us, someone with greater experience than mine, if this is so. Tell us if there are any of those delightful *sels* left. Is my experience this year only what one must nowadays invariably expect? Is "Tekel, tekell," written large on the wall? Does it mean that there have been no raisers of seedling English Irises among the last generation? I have an idea that sooner or later all varieties undergo this distressing change. But the pity of it!

Some varieties, of course, are more presentable than others, and if we keep them at a respectable distance are not so bad. I remember an old squire telling me what a shock he got when he first saw the face of the wife of one of his tenants. She had a beautiful figure and well cut clothes, and her back view was charming; but, poor woman, she was very plain when you saw the front view. It is much the same with the Irises now in flower. They are all right from the windows, but they are "plain" when you get a near view. It is a difficult matter to select the best. It would be going too far to call it a choice of evils, but it is getting on in that direction. They cannot help their looks; moreover, it is quite likely that it is man who does not fully understand their necessities who is in fault. Let me, then, conclude by giving the names of five of the most satisfactory. Snowflake (good white with faint rose markings in the standards), Prince Albert (mauve with

LUPINS AND BEARDED IRISES; DARTMOOR IN THE BACKGROUND.

competitor scoring fewer than 100 marks shall receive an award; the cash value of the prizes on this occasion was therefore £16 14s. 4d., which was distributed to the several recipients on the evening of the second day of judging. The premier position was taken by Mr. J. Wiltshire—as it has been regularly since the first inspection—with 189 marks; the second by Mr. W. Foster, with 156 marks; and the third by Mr. W. Palfrey, with 151. As usual, it was a very real pleasure to

June from the close proximity of Irises and Lupinus. The picture, I think, tells its own tale.—(Mrs.) ANNIE B. BUTCHER, *Tavistock, Devon.*

[Our correspondent is undoubtedly right as to the lack of appreciation of this particular combination. In a comparatively small proportion of gardens is justice done either to the Bearded Iris or the Lupin, so that it is scarcely wonderful that their value in combination is not widely recognised.—ED.]

purple blotches), Othello (rich dark blue with very dark markings), Socrates (tall dark purple with almost black markings), Starlight (late; purple standards with blue falls with a white centre). It was very noticeable the difference that the rain made in all the English Irises. I thought I had never seen such a miserable-looking lot of flowers as I saw at the R.H.S. Hall on June 27 and again at the Rose Show two days later. I

felt prepared to eat my hat if I had not a good deal better at home, but when I went into the garden on my return and saw the long bed I found to my horror that mine were just the same pitiable curled-up looking objects; obviously the dry spell with the hot sun and high winds had been too much for them. The change one long day's rain made was almost incredible.

JOSEPH JACOB.

GARDENING OF THE WEEK

FOR SOUTHERN GARDENS.

The Kitchen Garden.

Winter Tomatoes.—From seed sown at the end of June or early July healthy young plants should now be available. Directly they are sufficiently rooted and strong enough, transfer them into their fruiting pots, which need only be 8 ins. or 9 ins. in diameter. When potting them place a few ½ in. bones at the bottom of each pot, as this will prove beneficial when the plants are developing their fruits. Grow the plants under cool conditions, and pinch out the lead as soon as four or five trusses of fruit are set.

French Beans.—In addition to seeds being sown as advised in previous issue, it will be necessary, where it is essential that a constant supply of this vegetable be obtained as long as possible, to make use of cold frames to ensure success. Use fairly rich soil, and sow in rows about a foot apart, allowing each plant 9 ins. for development. It will not be necessary to put any lights on for some weeks, but encourage the plants to make a quick, clean growth by keeping them well watered and regularly syringed on warm days. Should a further sowing have to be made, this must be in frames where there is some heating arrangement to be made use of as soon as necessary.

General Work will include the removal of all exhausted crops, which may be burnt or taken to the rot-pit, as considered best and most convenient to carry out. Keep the hoe going as much as possible between all growing crops, and water such as Celery, Runners, etc., if possible, whenever necessary. Use diluted farmyard water freely on heavily cropped Beans. Allow no ground to be wasted by having blanks between any of the winter and spring greens. There is still ample time to get out more Leeks if wanted, and these later-planted ones are often much more appreciated than the early ones which grow so large, and a most important point, too, is that they keep well into spring without bolting.

The Flower Garden.

Lilium candidum.—August is the month to deal with this beautiful Lily, whether it be the planting of new bulbs or the division and replanting of clumps which have grown too large—it such be possible—or have lost something of their floral vigour. The position selected for the bulbs to occupy should be deeply dug and thoroughly well drained, and while full sun is not necessary during the whole day, the site should be a warm one. Avoid planting too deeply on heavy land, and introduce a liberal amount of gritty compost or some sharp sand around each bulb.

Woodland Walks frequently provide not only a charming retreat from the more formal garden walks, but are often the agencies used to open up vistas of the surrounding country. At this time, while leafage of all trees and shrubs is so luxuriant, care should be taken that overhanging branches do not mar good views, particularly so when the latter, a little later in the season, are rich in the many glorious autumn tints. Anything approaching a close trimming of trees in such rides should be carefully avoided, the aim being as natural an effect as possible. All long, coarse grass on and near such walks can be cut over at the same time, especially where it is growing round clumps of Ferns, etc.

Pansies required for spring display can be sown now in boxes of light soil in a cold frame. Prick out the seedlings when strong enough in nursery quarters. Unless a good strain is purchased, it is as well to leave Pansies out of the bedding scheme.

The Hardy Fruit Garden.

Wasps.—These pests are often excessively troublesome on easily worked soils, and it is necessary to commence the destruction of the

nests as soon as they are found. The most effectual way of dealing with them that I know of is to place a little cyanide of potassium in the mouth of the hole in the evening, afterwards placing a piece of turf over the hole. Follow this up next morning, if convenient, by digging out the nest, thus making sure of the destruction of the grubs. Cyanide is a deadly poison and needs handling with the greatest care. It should be mentioned that it can be used in the dry or liquid form. When used in the former way a small piece of the crystals about the size of a small nut is enough for a nest; to use the liquid, thoroughly soak a piece of cotton wool about the size of a hen's egg with it and place in the mouth of each nest.

Fruit Under Glass.

Muscats Grapes.—Many houses of Muscats are now approaching or have reached the colouring stage, and no effort should be spared which will be of assistance in enabling this queen of Grapes to finish in the highest possible manner. Make certain that the border is sufficiently moist and that sufficient nourishment has been supplied to the roots. Suppress all lateral growths likely to make too thick a covering, remembering that the old remark which says, "Light for white Grapes and cover for black" is true when applied with discretion. Maintain at all times a little pipe-heat as this ensures a freer circulation of air—a most essential point to bear in mind. See that any atmospheric moisture applied during daytime is dried up by early afternoon.

H. TURNER

(Gardener to the Duke of Northumberland),
Albury Park Gardens, Guildford.)

FOR NORTHERN GARDENS.

The Kitchen Garden.

Celery.—Dust the plants now with soot as a preventive from attack by the Celery fly. Where this pest is allowed to breed, the crop may be ruined, as the foliage becomes perforated and blighted, and this naturally retards growth. Spraying may also be done, and one of the most useful mixtures for this purpose is to boil a pound of coal-tar in a gallon of water for about twenty minutes, adding fifty gallons of clear water, and spraying every ten days for a period.

Globe Artichokes.—Cut the heads immediately they have attained a fair size and before they commence to open. If not required for immediate use they should be stood in water, changing it daily and placing the receptacles in a cool cellar.

Cucumbers.—Attend to plants in full bearing, and feed liberally so that the crop may be prolonged. Thin the laterals freely, and so permit light and air to benefit the young growths that are retained. No fire heat is necessary at this season, but advantage should be taken of solar heat by closing the pit early in the afternoon. Cucumbers in frames may be treated in similar manner, with the exception that less moisture will be needed, as the young fruits damp off readily if lying on the soil.

Winter Greens may yet be planted in quantity as ground is cleared. More especially is this desirable where, owing to want of space earlier in the season, the crop was limited.

Fruit Under Glass.

Pot Vines.—Where canes are required for early forcing next year the pots should be moved out of doors and placed in the shelter of a wall or hedge facing south. This position will prevent the young rods from sustaining damage from high winds, and yet allow full play of sun and air on the wood and buds. Pay strict attention to watering; at no time allowing the roots to become unduly dry.

The Flower Garden.

Layering Carnations.—Most of the Border varieties will now have sufficiently strong growths to allow the important work of layering to be proceeded with. Prick over the surface soil around the plants, and add a goodly quantity of sharp sand to keep the soil porous. Prepare a quantity of sifted soil, sharp sand and leaf-mould and use for placing round the parent plant, so that the layers may root quickly and establish themselves in other quarters early in September. After making the incision it is important that the layer be firmly pegged and placed in such a position that the young plant will be perfectly erect. Should dry weather prevail, the layers should be thoroughly watered, as root action is slow when the mounds of soil are allowed to become dry. Continue watering regularly until growth is noticeable.

Budding Roses.—Although this interesting work is not often practised in private gardens, there are many who prepare a few dozen Briars for this purpose yearly, and the present time is suitable for carrying out the work. Showery weather is preferable for the purpose.

Violets.—Where these are growing in nursery lines with a view to being transferred to frames later on, liberal attention should now be accorded the plants if the finest results are to be attained. The plants should receive copious waterings of liquid manure from the byre. Keep the soil between the lines well hoed or loosened with a Bencho cultivator. As red spider is apt to attack the leaves of Violets during dry weather, the foliage should be vigorously syringed as soon as the sun goes off them in the evening. As a preventive a small quantity of Abol insecticide added to the water will be found effective.

JAMES McGRAN

(Gardener to Sir Henry H. Houldsworth, Bart.),
Coodham Kilnarnock.

CONSERVATORY AND GREENHOUSE.

Pelargoniums.—Show and regal varieties that have been standing out in cold frames should now be cut back and the tops inserted as cuttings for young stock. The cutting pots may be stood on a shelf in a cool greenhouse, or the cuttings may be rooted in a cold frame, keeping the frame lights over them. When the old plants are starting into growth they should be shaken out and repotted into the same sized pots. If stood in a cool greenhouse they should be watered sparingly until the roots get a hold of the fresh compost.

Kalanchoes *flammea*, *Dyeri* and *kewensis* are all excellent plants for the cool greenhouse. Cuttings may now be inserted singly in small pots, and as they are all fleshy, succulent plants they root readily on a shelf well up to the roof glass in a cool greenhouse. When rooted they should have a shift into 48 sized pots, in which size they will pass through the winter. During the winter months they should be kept on the dry side. They all grow quite well in ordinary potting compost, to which should be added plenty of old mortar rubble, as these plants enjoy free drainage at all times.

Liriope spicata (syn. *Ophiopogon*) is an excellent plant for furnishing the conservatory and is useful for indoor decoration. The striped variegated leaves are very bright and pretty, and the spikes of bluish purple flowers are freely produced. Planted out as an edging to beds in the conservatory it is very effective at all times. This plant may be increased by division, and for furnishing purposes it is best grown in 48 sized pots. The plants may be divided at any time during spring or summer. They grow freely in ordinary potting compost in a cool house and must never be put in a stove temperature, or they will refuse to grow at all, the growing crowns making a hard rounded bud. In this respect the *Liriope* is unique, as most cool house plants will at least make weak and weedy growth when placed in a high temperature.

Muehlenbeckia platyclada.—Where green plants are required for mixing with other plants in the conservatory this species is very useful, as it quickly makes nice plants. It is easily propagated, either in spring or summer, by means of cuttings, which root readily in a close case with slight bottom heat. Like many other plants used for the embellishment of the conservatory and greenhouse, it is best grown in an intermediate temperature of some 50° to 55°. Good useful plants can be grown in 5 in. or 6 in. pots.

Cordylina australis and its several varieties are popular and useful plants for the conservatory, either as specimen plants for beds, or in their

younger state for the stages. The plants grow freely in ordinary good potting compost. As they become tall and leggy, the stem should be cut half way through just under the bottom leaves. A handful or two of moss should then be tied round the stem at this point. If the plant is kept on the dry side, and the moss kept moist, plenty of roots soon push out into the moss, when the top should be cut off and potted into a suitable sized pot, using a light, rich compost at this stage. If kept in a close, warm house for a few weeks it soon becomes established, when it may be removed to a cool house. If the old plant is turned out of its pot a number of so-called toes should be found; they are really underground stems, not roots as is generally supposed. Each has a growing point. These afford a ready means of propagation, and if they are cut off several inches long, the roots should be trimmed off, and the toes laid in fibre in a warm case, where they in time will produce leaves. They should then be lifted and put into small pots, afterwards potting them on as they require it. In addition to the green type, which varies considerably when raised from seed, there is the variety *purpurea*, or *lentiginosa*, a beautiful dark-leaved variety. The varieties *Doucettii* and *de Grootii* are both fine variegated forms. *Cordylina stricta*, *C. Haageana* and *C. Brianti* are smaller growing and elegant species, all very useful in the small state for decorative work. They are increased by means of toes; or the slender stems may be cut into short pieces which, if laid in fibre in a warm case soon produce roots and commence to grow. They should then be lifted and put into small pots.

Royal Botanic Gardens, Kew. J. COUTTS.

EDITOR'S TABLE

FROM Mr. C. H. Herbert, Acock's Green, came recently beautiful flowering sprays of some of his newer Pinks (*Herbertii*). These included three varieties all salmon tinted, namely, *Bridesmaid*, the charming pale salmon which received an award of merit at Chelsea; *Mrs. Giffard Woolley*, an exceptionally large and handsome flower the exact shade of *Enchantress Carnation*; and *Prince of Wales*, a bright rosy salmon variety also of large size, but more loosely built and with larger petals. The last two are not yet, we believe, in commerce, but they should be eagerly sought after when marketed.

The True Gum Cistus.—Do not plant that magnificent species of Rock Rose, *Cistus ladaniferus*, under the impression that it is a dwarf grower suited to the rock garden—for it is not! Indeed, it is more truly a shrub than most and reaches a height of between 3ft. and 5ft., although it is a very slow grower and takes many years to attain this height. At the same time, this should be allowed for when planting, so that, as it does extend, less valuable plants can be scrapped to make room for this very handsome specimen. A sunny position should be chosen, for it is apt to be badly cut by severe frosts in winter where exposed in the open, especially if north and easterly winds sweep across it. A light soil suits it well, and it is splendid for planting where the ground is very thin and sandy. During July the bushes are most effective when covered with the immense solitary white flowers, at the base of each petal of which is a large deep purple blotch. Visit it early in the morning when these have first expanded and you will be amazed at their beauty, while fresh buds expand every morning so that it is striking and effective for many weeks. No pruning is required, beyond cutting out any dead wood in spring after the new leaves are well in view.

A Charming Poppywort.—That beautiful Chinese plant *Meconopsis integrifolia* is one of the most precious gems that the rock garden can show when seen at its best in June and July.

Not so many years ago it was an entire novelty, and even now is but seldom seen and, in spite of its extreme beauty, seems likely to remain a scarce plant.

Culturally, it does not love the sunlight over-much, but appreciates a spot fully in the open where it receives plenty of light within the shade of—but clear from the overhanging boughs of—a belt of trees. Their preference in soil is a mixture of fine peat, leaf-mould and sand, which should always be evenly moist. Sometimes great success can be attained by growing in a very sunny place on the outer margin of the log garden, where the soil does not dry out; but there is always a certain amount of risk in this compared with a shadier spot, for an excessively wet period may cause rotting of the plants, while a prolonged drought may easily cause the outer fringe of the bog to shrink, leaving them high and dry. Owing to the woolly nature of the leaves, protection from wet in winter is absolutely imperative. This can be supplied by means of a pane of glass secured a few inches above the plants so that the air can circulate freely beneath. The plants are perfectly dormant all the winter, and the glass may be left on until growth commences in early spring. The appearance of the plant is that of a rosette of beautiful woolly green leaves, from the centre of which rises a central stem to a height of about 2ft., carrying large primrose yellow flowers with bunches of stamens of the same hue. It is worth noting that there are two forms of this species, that first discovered bearing several flowers, each on a separate pedicel which branches from the main stem. The second variety does not branch at all, so far as the stem is concerned, but produces one flower at the termination of each, although it pushes several stems from every root.

Pannonian Clover.—An uncommon, but not showy plant is the Pannonian Clover, *Tritolium pannonicum*, which begins to bloom in June and continues in flower until September. The flowers are pale yellow, but of a deeper shade than ordinary Clover. They are, moreover, much larger and are borne on plants a foot or more in height, which varies considerably according to the nature of the soil. The foliage has the characteristic features of the genus, and the flower heads, which are of large size, are more conical than those of the common field Clover. The plant is naturally an object of interest to farmers, but it is doubtful if it has any value for forage purposes. As a border flower, however, it is quite good. It is, indeed, just one of those plants which attract and interest all garden visitors. It may be raised from seeds or increased by division. The root-stock is very hard and division is, on the whole, rather difficult. *T. pannonicum* thrives well in ordinary garden loams.

Two Useful Thalictrums.—While there are many who grow the more vigorous sorts of *Thalictrum* which have an attractiveness both from the point of foliage and blossoms, as represented by *T. aquilegifolium* and *T. dipterocarpum*, quite a number, for reasons not always understood, leave out of their purview altogether varieties the special charm of which lies in their dainty fronds. In this connexion our mind turns to two sorts we have long grown, viz., *T. adiantifolium* and *T. a. minus*, the latter being comparatively dwarf, seldom exceeding more than a foot in height and—as its name implies—bearing a close resemblance to the tender Fern of that name. The one under notice asks for no other treatment than that accorded to *Thalictrum* in general, viz., fairly light soil in which leaf-mould or vegetable matter is incorporated, well drained, and a position where partial shade predominates, as under a pergola, for instance. So many over-

look these daintier varieties of the Meadow Rue, yet they are practically as hardy as the more robust sorts.

Garden Refuse.—There are, unfortunately, many amateur gardeners who do not realise the value of decayed vegetable matter in the garden. They invariably burn it. In the majority of gardens, both large and small, there is generally an odd corner where a hole could be dug and the refuse thrown in. Of course diseased plants are best burnt. The material so collected and placed in the rot-pit should be turned occasionally in order to hasten decay. By the time that autumn arrives there will be valuable manure for the garden. A light covering of earth may be placed over the material. Occasional waterings will be helpful. As regards hard-wooded material, this should be burnt, as its decomposition may take years to effect if placed in the rot-pit and while decaying it affords a breeding ground for fungi. The ashes obtained from burning hard-wooded branches should be saved and kept dry. They form a very efficient and practical substitute for artificial potassic manures.

The Leucothoes.—In gardens, the genus *Leucothoe*, one of the Heath family, is best known by *L. Catesbaei*, a spreading evergreen shrub which bears great quantities of white flowers, but on the lower side of the branches, so that they are largely hidden from view by the leaves. That species is found in mountainous regions on the eastern side of North America; *Leucothoe Davisæ* is a native of California. The branches are erect and the flowers are shown to great advantage. The racemes are 2ins. to 4ins. long, the flowers nodding, pitcher-shaped, about a quarter of an inch long and white. They open in June. The foliage is evergreen, and very firm in texture.

National Diploma of Horticulture.—We are informed that the Royal Horticultural Society's National Diploma in Horticulture has been awarded to the following as a result of the written and practical examinations for the diploma held this season:

Section 1. General Horticulture.—Miss D. F. Cavalier, Burgess Hill, Sussex; Mr. S. J. Channing, Sutton Scotney, Hants; Miss C. Choules, Hornchurch, Essex; Mr. H. Gethen, Mondamin, West Mersea, Essex; Miss M. H. Hemming, Hayfield, Derbyshire; Miss K. L. Syer, Charlton, East Sutton, Maidstone, Kent.

Section 1(b). Fruit and Vegetable Growing.—Mr. C. J. Glead, Winchester, Hants; Mr. H. F. Maidment, Cannington, Bridgwater, Somersetshire.

Section 1(c). Fruit Growing.—Mr. J. W. Hall, Edinburgh; Mr. D. G. Henry, Portobello, Midlothian.

Section 6. Public Park Gardening.—Mr. F. Baker, Wigan, Lancs; Mr. L. E. Morgan, Crews.

Section 7. Horticultural Inspection.—Mr. C. H. Oldham, Chandlersford, Southampton.

Trial of Early Strawberries at Wisley.—The Royal Horticultural Society will carry out a trial of early Strawberries in their Gardens at Wisley during the coming season. Twenty plants of each variety to be tried should be sent to reach The Director, R.H.S. Gardens, Wisley, Ripley, Surrey (from whom the necessary entry forms may be obtained) on or before August 15, 1922. Only early fruiting varieties should be sent.

Trial of Antirrhinums Under Glass at Wisley.—The following awards have been made by the Council of the Royal Horticultural Society to Antirrhinums grown in pots under glass at Wisley. Awards of merit.—Snowflake, Canary Yellow,

Crimson-Scarlet, The Bride, Canary Bird, Captivation, Morning Glow and Flegance, all sent by Messrs. Barr; Yellow, Maize Queen, Amber Queen and Moonlight, all sent by Messrs. Dobbie; Yellow Queen, from Mr. Dawkins; Golden Gem, from Mr. Dawkins and Messrs. W. H. Simpson; Rose Queen, Queen Victoria, Esme and The Fawn Improved, all from Messrs. W. H. Simpson; Prima Donna, from Messrs. Barr and Messrs. Veitch; Coral Red, Maize Queen and Lilac Queen, from Messrs. K. Veitch; Queen of the North, from Messrs. Toogood; Firelight, from Messrs. Dickson and Robinson; Cerise King, sent by Messrs. Watkins and Simpson; Bonny Lass, from Messrs. Barr and Messrs. Watkins and Simpson; and The Fawn, sent by Messrs. Webb, Highly commended.—White Beauty, from Messrs. Dobbie; Rose Doré, from Messrs. Watkins and Simpson; Salmon Queen, from Messrs. Dickson and Robinson; Admiration, from Messrs. Barr.

Imperial Fruit Show.—From October 27 until November 4 the Daily Mail Imperial Fruit Show is to be held at the Crystal Palace. The schedules and prize lists of the commercial and amateur sections are now obtainable. Entries are free in all amateur classes. The schedules may be obtained from the Secretary, Daily Mail Imperial Fruit Show, 130, Fleet Street, London, E.C.4. Intending exhibitors should state when writing whether commercial or amateur's schedule is required. Entries close for commercial section on Monday, October 2 and for the amateur section on Saturday, October 14.

Manual of British Botany.*—This is the tenth edition of the late Mr. Babington's book, which has been brought up to date by Mr. A. J. Wilmott, B.A., F.L.S., who is an assistant in the Department of Botany at the British Museum. This useful little book contains 612 pages of matter invaluable to the botanist. Of convenient size, the book will slip in one's pocket, so should be of great assistance to those on botanising excursions.

* "Manual of British Botany." Edited by A. J. Wilmott, B.A., F.L.S. Published by Gurney and Jackson, 33, Paternoster Row, London, E.C.; price 16s.

ANSWERS TO CORRESPONDENTS

QUESTIONS AND ANSWERS.—All communications should be clearly and concisely written on one side of the paper only, and addressed to the EDITOR OF THE GARDEN, 20, Tavistock Street, Covent Garden, London, W.C.2. When more than one query is sent, each should be on a separate piece of paper. Plants for naming should be clearly numbered and securely packed in damp grass or moss, not cotton-wool, and flowering shoots, where possible, should be sent. It is useless to send small scraps that are not characteristic of the plant.

FLOWER GARDEN.

POPPIES UNSATISFACTORY (A. E., Troon).—The specimen sent throws no light upon the cause of the comparative failure unless the plant is in a different position from others in the garden and is exposed to conditions of moisture, etc., which render it liable to attack by the fungus *Rhizoctonia*, which seems to be present.

CLARKIAS DYING (D. K. T.).—The symptoms described suggest the attack upon the Clarkias of one of the fungi which cause collar rot—a species of *Fusarium* possibly. Probably treatment of the soil with lime would act as a preventive in future.

STACHYS LANATA IN WINTER.—(A. E. B., Bermondsey).—The Lamb's Tongue is usually quite hardy except on wet, heavy soils, but such woolly-leaved plants are generally susceptible to frosts, which will probably account for the plants dying in winter. This difficulty could be overcome by wintering a sufficient quantity in a cold frame. The plants should not be subjected to artificial heat and abundant ventilation should be given whenever the weather permits.

TRANSPLANTING MADONNA LILIES (A. Mithou).—If it is really necessary to transplant the bulbs of *Lilium candidum*, the best time to do so is about the middle of August, and the work can be continued until the latter part of September, but it should always be borne in mind that these beautiful Lilies resent interference and thrive best when left undisturbed. Should it be that the bulbs have not been flowering satisfactorily of late years suggest that, instead of transplanting, as much of the soil as possible be removed and replaced with a mixture of good loam, sand and bone-meal.

IRIS SIBIRICA (Felsted).—We have not experienced any difficulty with the Siberian Iris. It is generally a very accommodating plant—one that will thrive under a variety of conditions. The greatest success is met with when it is planted in good soil in a moist position exposed to full sunshine. It is an admirable species for waterside planting though it will also flower well in the hardy plant border.

ESTABLISHING BERGAMOT (Felsted).—If the true Bergamot (*Mentha citrata*) is meant, this should be quite easy to establish. It should be planted in an open position, in a moderately moist soil for preference, during February or March. The roots should never be allowed to become really dry. Although *Mentha citrata* is a native of Britain, it is a scarce plant in gardens. *Monarda fistulosa* is the wild Bergamot, and this is of easy cultivation in ordinary garden soil, but it is inferior as a garden plant to *Monarda didyma*. Either of the *Monardas* may be propagated by root division in the autumn or early spring, which also are the best times for planting.

TREES AND SHRUBS.

PROPAGATING THE DOUBLE POMEGRANATE BY CUTTINGS (N. W.).—Cuttings of this year's young growths are by this time fairly firm, and are ready for insertion now. Remove the shoots with a very thin portion of the old wood attached (termed a heel). Insert the cuttings fairly firmly in pots of soil composed of equal parts of light loam, leaf-mould and coarse sand, with a thin surfacing of fine sand to trickle in the holes when dibbling in the shoots with a pointed stick. Cover each pot with a bell-glass or place several pots under a bell-glass or hand-light.

LAYERING A WISTARIA (N. W.).—Layering may be done in pots as suggested provided our correspondent is able to elevate and fix them in suitable positions. The points selected for layering should be near the commencement of this year's new growths where by this date the wood is fairly firm. Fix the stems firmly in the soil with pegs and then give each growth a stake in such a position that there is a decided bend or twist in the stem to check the flow of sap. Remove the tops of the shoots. Always ensure that the soil in the pots is kept moist.

WINDBREAK FOR NORTH-EAST ASPECT (Felsted).—Both the white Poplar (*Populus alba*) and the two Willows (*Salix alba* and *S. caprea*) will stand a good deal of wind; while, as our correspondent suggests, the Hornbeam and Beech, though good for the purpose, are rather slow growing. Other suitable trees would include the Austrian Pine, Scots Pine, *Populus deltoides*, the Cornish Elm, the Wych Elm, Sycamore and the White-beam (*Pyrus Aria*). If the area is of moderate extent, we suggest the use of the Austrian Pine, White Poplar, Beech and Sycamore in mixture. Should a purely evergreen screen be desired, it might well be composed of Austrian Pine, common Spruce and the Evergreen Oak. If *Cupressus macrocarpa* thrives in the locality, it should be added in any case. As sturdy growth is required, the planting should be done as firmly as possible, and quite off distance should be allowed from tree to tree.

ROSE GARDEN.

ROSES (Felsted).—Jules Margottin is a tree-flowering and hardy Hybrid Perpetual Rose, and the same may be said of Dr. Andry. If they are given a dressing of loz. of nitrate of soda to the square yard now, repeating it a fortnight later, a second growth should be obtained with flowers in autumn. Dr. O'Donell Browne is a Hybrid Tea and more reliable in the autumn than the above. Joseph Hill is another and blooms freely. Single plants cannot always be depended upon to give the desired results, because individuals are liable to many mishaps. This is not the fault of the variety, however. The dwarf Polyanthas, Mrs. Taft and Jessie, are very free and continuous-flowering Roses suitable for bedding, but they are liable to mishaps. A frosty night will injure the young flower-buds, and the same thing may happen if they get badly infested with aphids. Frost did much damage this year early in June, and many varieties of Roses were injured.

THE GREENHOUSE.

PROPAGATION OF MESEMBRYANTHEMUMS (W. R. J., Cornwall).—*Mesembryanthemum* can be readily propagated by cuttings made of the growing shoots (not flowering shoots) and by pieces broken off from March to August. Use very sandy soil mixed with old mortar rubble and broken soft brick. A suitable proportion would be two parts fibrous loam and one part of sand, mortar rubble and brick. Place the cutting pots on an open shelf, not in a close propagating frame.

PLANTS FOR COOL GREENHOUSE (E. W.).—In addition to Geraniums, Ferns, Lilies and Hydrangeas, it is only possible briefly to outline a list of suitable plants. Put up now bulbs of *Freesias*, *Lachenalias*, Roman Hyacinths and Paper White Narcissi; also, in a few weeks' time, pot bulbs of *Daffodils*, Tulips and Hyacinths. During the summer, tuberous *Begonias* and *Euchsias* are delightful and worth cultivating largely. *Primulas obconica* and *Kewensis* flower freely in winter with very little heat. If the greenhouse is not large, root cuttings of *Chrysanthemums* in April and grow them to flower during the autumn and winter in 6in. (32 size) pots. *Aureolias* are fascinating small plants to grow in pots for the cool greenhouse. The *Chimney Campanulas* (*C. pyramidalis*), raised from seeds, *Bouvardias*, propagated by cuttings, *Indian Azaleas*, *Cytisus fragrans*, *Phyllocactus*, *Epphyllums*, *Clivia miniata* and *Cannas* may all worthily receive attention. "The Greenhouse and How to Make the Most of It," published at this office, price 11d. post free, would afford help as regards culture.

RETTARDING CINERARIAS (C. Scot.).—The most important details in the culture of *Cinerarias* are: (1)

Throughout their growing period cultivate the plants under cool conditions. In winter only give sufficient artificial heat to keep out frost. Now and in early spring a north frame or house facing north is practically essential. (2) Give the plants ample size pots, cramped (pot-bound) roots tend to force the plants to push up the flowering stems. (3) Do not crowd the plants at any period of their growth, and keep them near the roof glass. (4) Shade fairly heavily in spring if the sun is bright, but open the doors and ventilators wide, damp the floor and stages to keep the atmosphere cool. (5) If, as suggested, when potting plenty of space for soil is allowed provided the plants make ample leafage, only give liquid manure for the last month before the plants are required in full bloom.

FLOWERS FOR DECEMBER (C. W., Cheshire).—To commence now it will be necessary to rely largely upon bulbs for December flowering. Roman Hyacinths, Paper White Narcissus, double Roman Narcissus, *Daffodil* *Cervantes* and the *Cynthella* (*Miniature*) *Hyacinths* can all be obtained in flower during December with very little trouble if potted early in August. As our correspondent appears to have plenty of greenhouse accommodation, the *Duc van Thol* Tulips should be of value. Bulbs of the latter may be forced gently in a warm greenhouse during November. Retarded Lily of the Valley crowns, *Freestias* and *Lachenalias* would also be useful. A heated greenhouse filled with single and double-flowered *Zonal Pelargoniums* (*Geraniums*) would give an abundance of flowers to cut during December. There are also several annuals which could be sown now with every hope of a display of blossoms. Ten-week Stocks, including the Beauty of Nice varieties, *Nemesia stramosa* *Suttonii* and *Calendula officinalis* Orange King and possibly *Mignonette* if sown at once would be worth trying.

FRUITS UNDER GLASS.

VINES ATTACKED (A. W.).—Probably a drop of petrol injected into the holes which the beetles are boring would check the pest which our correspondent describes; but is it certain that the parts of the Vine attacked are alive, for it is very unusual for beetles to attack living active tissues of Vines in this way?

PEACH TREE NOT SATISFACTORY (Wood Dean).—It is just possible that the Peach flowers were damaged by a severe night frost; this has occurred in several cases during the past season. The transplanting of the tree may have caused a serious check, especially if the roots suffered at any time through lack of water. The small-flowered varieties are generally freer setters than the large. The variety Hale's Early sometimes fails to set well under glass, but rarely ever fails to do so in the open air. All Peach trees transplanted under glass should be allowed to grow slowly the following spring and with abundance of air during open weather. Peach Duke of York would suit you admirably; it is a strong grower, does not drop buds, sets freely, has large and very highly coloured fruits. Nectarine Humboldt, a grand variety, would prove equally suitable and satisfactory.

GRAPES ATTACKED (Usk).—Dust the leaves of the Vines with sulphur, or paint the pipes with milk of sulphur, in order to rid the Vines of red spider. Barron's Book on Vines is one of the most useful ever written on this subject. So far as we know, no varieties of Grape are more prone to attack by red spider than others. The fruit sent was immature. Please send mature fruit and a typical leaf for identification later on.

FRUIT GARDEN.

CATERPILLARS ON FRUIT TREES (J. N., Forfar).—The caterpillars attacking our correspondent's trees are those of one of the Tortrix moths or leaf rollers. It is almost impossible to do any good with lead arsenate spray at present, but it would be advisable to use it next year as soon as the petals have fallen. The best plan now would be to kill what caterpillars are found, and thus prevent the moths from developing and laying their eggs on the trees. Our correspondent would be well advised to spray his trees next spring just as the buds are showing green at the tips with lime sulphur at the rate of 1 gallon concentrated solution to 12 gallons of water. This will make for general cleanliness and freedom from pest attack.

KITCHEN GARDEN.

FRENCH BEANS AND IRISES ATTACKED (Iris).—The French Beans have been attacked by one of the soft rot bacteria allied to that which is causing the rotting of the Iris which is also sent for examination. In both cases destruction of the diseased portions and the treatment of the soil with superphosphate is called for.

MISCELLANEOUS.

THE DESTRUCTION OF ANTS (E. E. B., Sussex).—Make a hole in the nest of the ants and pour hot water into it, or a teaspoonful of carbon bisulphide, filling the hole up immediately afterwards. In either case the operation should be performed after dusk when the ants are at home.

HOW TO TRAP MOLES (N. P. H., Witley).—The best method is to set proper mole traps in the most used run which can be found. Do not handle the trap with the bare hand and fill in the run on either side of and around the trap, otherwise daylight percolating into the run will probably put the vermin on guard.

NAMES OF PLANTS.—"Stoke Prior."—Roses: 1, Dr. Van Fleet; 2, Edmond Proust. —E. M. A. R.—1, *Sedum ruberum*; 2, *S. album*; 3, *Achillea umbellata*; 4, *Geranium lancastrisense*. —E. F. W., S. IRISES FOR THE WATERSIDE

Abundant rains have ensured that the planting season shall be satisfactory.

THE only known species of Iris which really likes aquatic conditions in Britain is our native Flag, *Iris Pseudacorus*, but there are many others which, to do themselves justice, require abundant moisture. All these have somewhat sedge-like foliage which peculiarly fits them for the task of adorning lake or stream-side.

All Irises have sword-like foliage, but it is worthy of remark how this differs in character according to the cultural requirements of the plant. The truly aquatic common Flag has lush green swords which harmonise with those of other water-loving plants. *Iris sibirica* has quite distinct foliage but with the same bogland character. In the cultivated Japanese varieties listed as *I. Kämpferi*, a broader spread of leaf is noticeable, though the lush greenness is still discernible, but when we come to the rhizomatous Bearded Irises, the thin sedge-like foliage has become thickened, almost succulent, and the rich greens have become bluish or whitish greys. Speaking generally, the cultural requirements of an unknown Iris may roughly be made out from a study of the foliage.

The most suitable species of Iris for the wateredge might be tabulated like this:—

For shallow water.—*I. Pseudacorus*.

For wet ground, liable to occasional winter flooding.—*I. sibirica*, *orientalis* (and hybrids between these two), *ochroleuca*, *aurea*, also *I. x ochraurea* and *I. versicolor*.

For well cultivated and well drained ground, not subject to flooding, the *Kämpferi* Irises, *I. Monnierii*, *I. siphoides* forms (English Irises), *I. Delavayi* and the Gladwyn Iris (*I. frétidissima*) especially valuable for autumnal berried effect.

Of *Iris Pseudacorus*, so well known to all lovers of the countryside, there is little to be said except that it grows most vigorously when provided with shallow water the year round, but flowers under such conditions very sparsely. It may be induced to grow and flower well in any decently cultivated land, but probably shews to

best advantage on land subject to winter flooding, but which bakes hard and surface-dry in summer.

Iris sibirica, a European species, is very closely related to *I. orientalis*, an Asiatic. The latter bears larger flowers, indeed some selected varieties approach the cultivated *Kämpferi* forms in size, but the plants lack the easy graceful bearing of the

*sibirica*s and are apt to hide their flowers among the tips of the foliage. No species of Iris—and this is saying a great deal—is much more variable than *I. sibirica*, but a good form is, when in flower, a joy to behold. The grace and beauty of the plant is best appreciated when one sees an outlying clump with its abundant, almost grass-like, foliage far over-topped by the sheaves of wiry flower-stems each bearing a number of flowers and flower buds, not large but dainty. The typical blossom colour is some shade of rich purplish blue, but the variety Perry's Blue, which has, probably, *orientalis* blood, is almost certainly the nearest to true blue in colour of any Iris in cultivation. Even this beautiful form, however, has hardly the grace of the dusker-shaded forms. The so-called white form of *I. sibirica* is a semi-transparent looking dirty cream. *Iris orientalis* Snow Queen, however, though it has little of the *sibirica* habit, is a beautiful pure white variety, more worthy, in the writer's estimation, than any of the rather numerous coloured forms.

Irises *ochroleuca* and *aurea* are giant moisture-loving Flags which, in rich damp soil, often reach 6ft. in height. The former has flowers white at the margins but deepening to yellow towards the centre and blotched with yellow on the falls, and the latter blossoms of a deep rich golden shade. *I. ochraurea* is a vigorous and free-flowering hybrid between these two, and *I. Monnierii* is in appearance a lemon-yellow *ochroleuca*, but, though it likes rich soil, seems not to tolerate excessive moisture.

Iris versicolor is practically a New World form of *Pseudacorus*, with flowers, however, of a purplish cast, varying according to the type selected, from indeterminate washy mauves to purplish blues in somewhat the colour range of *I. sibirica* and including the rich red-purple listed as *I. v. Kermesiana*.

The colour range of the Japanese (*Kämpferi*) Irises is very extensive, but it is difficult to suggest a list of varieties, since the names of them are legion and it is often impossible to procure any

THE GIANT IRIS OCHROLEUCA 'N THE BORDER.

particular sort. White, lavender, red mauve, blue mauve, blue purple and red purple all are represented, and there are blotched, veined and edged forms in practically every tone of the colour range. In addition, there are two distinct types of flower in this Iris, the ordinary single forms with incurving standards and slightly reflexing falls, and the so-called double forms in which all the six components of the floral envelope reflex slightly to form an almost tabular flower. These latter always appear larger, but the single forms have more real beauty of outline.

The English Irises are bulbous, closely related, to the Spanish and Dutch (*Niphium*) strains, but the appearance of the flowers both as regards form and colouring favours rather the single Kämpferi forms. In rather stiff moist soil these Irises have a real distinction which none of the Spanish—no, not even the remarkable Thunderbolt—possesses.

Unfortunately, the English Iris has received, of late, less attention from the hybridist than have the Dutch and Spanish strains. As, moreover, the beautiful self-coloured forms always "break" sooner or later into often worthless mottled ones, it is not now easy to get together a really representative collection. On some soils the English Irises flower more freely than the Japanese. Although bulbous they do best when left undisturbed for several seasons.

Iris Delavayi is a tall species related to *I. sibirica* and *orientalis*, but of less easy culture. It seems to do best in soil not actually boggy, but with water at all times in reach of its roots. The flowers are dark purple, blotched white.

The dingy flowered Gladwyn, which covers the sand dunes on some of our coasts, needs little description. Its specific name—*fœtidissima*—is due to the unpleasant odour given off by the leaves when bruised. There is a yellow flowered form which, though not brilliant, is at any rate an improvement on the type. Both set seed readily and it is for these brilliant seeds which, in their split pods, always remind one of the burst fruits of the Spindle Tree, that the plants are grown. The variegated leaved form seems never to flower, so is worthless for autumn effect.

The present month is a suitable time to plant English Irises, though planted next month or in October they also answer well. Now that flowering is finished the Japanese Irises move well. Care should be taken not to transplant these during winter or it is more than probable that there will be a large percentage of losses. Spring planting answers, but is less satisfactory. Such tall Flags as *aurea*, *ochroleuca* and *Monnierii* also move well at this season, so do *versicolor*, *Pseudacorus*, *sibirica* and *orientalis*, though all these transplant fairly well throughout the usual planting season, except, perhaps in the dead of winter.

These waterside Irises all like moderately rich soil, so that well decayed farmyard manure—cow dung for preference—decayed leaves, etc., should be incorporated during the work of preparation. The Japanese Irises and others will not tolerate soil at all boggy, but should have the ground thoroughly well trenched for them as, however near the waterside, they may be planted, they will receive little moisture by capillary action if there is a hard dry pan just below the roots.

Given an adequate amount of moisture at the root, all Irises flower best if planted in almost full sunlight, so that half-shady spots around pool or at brook side should be reserved for shade-loving plants such as *Spiræas*, which, incidentally, form a pleasing foil, with their soft and somewhat rounded outline, to the stiff spiry Irises.

Lime, so essential to the Bearded Irises if drainage rot is to be avoided, is, as might be expected, inimical to the waterside species.

PROPAGATING ROCK PLANTS

The showery weather experienced since the last week in June has been favourable for propagation. There is still time to divide or to take cuttings of many alpines and other dwarf plants.

THIS is an excellent time to take cuttings of *Violas* of all sorts and such rockery species as *V. V. gracilis*, *cornuta*, *bosniaca*, *canina*, *calcarata* and *lutea*, are no exceptions to the general rule. The Grecian *V. gracilis* is a charming species, easy to grow, compact of habit and with lovely velvety purple flowers. It should be found in every rock garden, however small. The Horned Violet, *V. cornuta*, is a rampant growing and well known plant. It has nevertheless many virtues, being almost perpetual flowering and admirable for cut flower. *V. c. purpurea* is the most effective form of this, though the French grey and white varieties are also useful. *V. osiaca* is more uncommon than either, very easy;

Similar compost will answer for the nearly related *Onosmas*, but owing to the woolly surfacing to the foliage, great care in ventilation is necessary to prevent wilting and at the same time to guard against "damping off."

This is the season when, if one has the heart to do it, one may divide established clumps of those quaint South American *Oxalis*s. *O. O. enneaphylla* and *adenophylla*, the former from the Falkland Isles and the latter from the Andes of Valdivia. It is better to establish the divided pieces in pots and put out the resultant plants next spring. *O. enneaphylla* is generally supposed to like a shadier corner than the other species mentioned, but the writer has had them growing side by side

struck—division is better unless close attention can be given the cuttings until they are fairly rooted. The various forms of *S. oppositifolia* divide easily enough, but should be established in pots before planting out. The minute but related *S. retusa* also divides readily.

PERENNIALS FROM SEED

ON pages 137 and 138 there appeared an interesting article on the raising of alpines from seed, and several very useful "tips" were given on the treatment of various kinds to ensure the best possible percentage of germination. Always, on reading any article on this fascinating subject, I think how very useful it would be if all the known data of seeds which require special treatment were collected and published in book form. Seeds are, to my mind, one of the great wonders of creation, and much could be written of their infinite variety, beauty of form and the means adopted by Nature for their distribution, but what chiefly concerns the cultivator is how to coax them to germinate under artificial conditions after being dried and stored, which is contrary to Nature's way of sowing as soon as ripe.

Many of them which grow in almost any soil are wind-borne or carried to a distance by bird or beast; others which need a special soil for their growth tall near the parent plant, where they are certain to find their special need supplied. Books on the cultivation of the plant spring up like Mushrooms, but I know of none which deals entirely with the more interesting work of growing the plant from seed. The old hand generally has the memory well stored with information on the subject, but those of less experience and fewer opportunities treat all seeds much alike, and in consequence meet with so many failures that they soon get discouraged and give it up in despair. A guide as suggested above would go far to alter this and give to all a more equal chance of success. When seeds of an unknown or untried kind come to hand in sufficient number the grower of experience does not trust all the eggs in one basket, but tries in as many ways as seem necessary and notes results for future guidance; the inexperienced use one pan, one compost, and trust to luck. Personally, I have met with a few instances which may be worth giving.

Here, on a cool soil in East Surrey, *Tropaeolum speciosum* does well, and when visitors see a mass of it, perhaps rott. high, with its glorious trails of scarlet on an evergreen shrub, they at once want either seeds or roots. As disturbance of the roots soon destroys it, seed was usually given—and rarely grew, and I set myself the task of finding out why it failed. Experiment proved that quite a short period of drying killed the seed, and also that seed properly stored required a whole year before germination took place. I adopted the plan—by no means new—of storing the seed in damp soil. Drainage was placed in a pot and a small quantity of soil, then ripe seed as collected and soil was added until the pot was full. This was kept in a peach house, and the soil was never allowed to become dry until well on into the second winter, when the seeds began to vegetate and the pot was at once moved to even colder quarters. The mystery was now solved, and towards the spring the seeds which had not germinated were distributed packed in damp soil or moss with instructions for sowing at once near or under shrubs, where disturbance,

THE ALTOGETHER CHARMING CREAMY WHITE OXALIS ENNEAPHYLLA.

of rosy-mauve hue with just a hint of magenta. Good forms of the Dog Violet, *V. canina* are very beautiful. Of the colour forms a deep violet blue is the best, but a good albino is in commerce. The Dog Violet may be readily increased either from cuttings or by division. *V. calcarata* is a very variable plant and many forms are very weedy-looking in the garden. *Viola lutea* of our own Northern hills is a much better and more constant plant and quite easily propagated.

There is still time to take rooted cuttings of *Phlox subulata*, but the plants will not, of course, be as large next spring as those set out two months ago. The same remark will apply to *Aubrietias*, *Arabises* and *Alyssums*. *Lithospermums*, both the commonly seen prostratum forms and the even more beautiful *L. L. granifolium* and *petreum*, with the hybrid intermedium, increase fairly readily from cuttings of half ripened wood in pots or pans of *well* sandy soil in a cold frame. To ensure the sweetness of the compost it is well to add a little crushed mortar rubble. Most *Lithospermums* love lime. *L. prostratum* is not so particular, but it dislikes a noticeably sour soil.

in a sunny nook of the rock garden and in gritty soil. The equally beautiful autumnal flowering *O. lobata*, with yellow blossoms, if not already divided should now be left for another season.

The present season has favoured the growth of *Primulas* of every kind. This is quite a good time to divide the more or less auricula-like species, such as *P. P. Auricula*, *hirsuta*, *villosa*, *pubescens* and *marginata*. Frequent division or, where suitably placed, top-dressing is very necessary with the last named, the leggy habit of which is otherwise an eyesore.

Almost all forms of *Saxifrage* may still be propagated. The Mossy (*Dactyloides*) section may be divided under lights outdoors, or rooted from cuttings inserted in very sandy compost in pans or boxes in a cold frame. The latter is the better method if a large stock is required in the minimum of time. The enrooted forms may readily be divided so that a little root remains to each plant to be. The knife may have to be employed to effect this however. The turfed (*Kabschia*) forms may be carefully divided, retaining as much root as possible to each portion, or cuttings may be

of seeds or roots was unlikely. This proved quite successful in those cases where soil and situation were favourable to its growth.

Another case comes to my mind where a short period of dry storage of some tree seeds delayed germination for a whole year. My employer owned woods in East Kent in which the "Wild Service" tree, *Pyrus Tominalis*, known there as Chequers, grew. Although they bore fruit abundantly, self-sown seedlings were rare, and as increase was wanted I was requested to grow a good batch, and received a quantity of fruit for the purpose. When quite ripe the seeds were washed out and a part was sown at once and part kept and sown in the following spring. The autumn-sown seed germinated well in the spring, but that which had been stored and sown in March lay dormant for a whole year and then germinated, as well as the autumn-sown seed had done in the previous spring. Seeds of *Pyrus japonica* sown at the same time behaved in exactly the same way, thus proving that Nature's way of sowing is best when the seed can be protected from its enemies.

Shingle and the washings of compost from pots during watering would not appeal to many as an ideal medium in which to sow seeds, but the staging in the greenhouses here is entirely of iron and the corrugated iron beds are covered with this material, and it is found that many seeds germinate in it more freely than in ordinary compost. Seeds of greenhouse *Primulas* germinate like Mustard. Even two year old seeds come well, and form such a mass of roots that scarcely any check is given when transferring to pots. With *P. malacoides* I stand plants on it when ripening seeds, and obtain all the plants wanted without further trouble, and if any are left they grow and flower well, yet plants in small pots with less moisture often damp off. *P.P. obconica*, *kewensis* and *sinensis* come well, and doubtless others of this rather difficult class would succeed if tried. Many other greenhouse plants are self-sown in the same way. H. C. W.

ESSENTIALS OF GARDEN DESIGN

III.—PROPORTION.

IT is self-evident that the first gift necessary for anyone who aspires to be a designer—no matter what he may seek to design—is a fine sense of proportion. Some folk have a colour sense so refined that it is almost, if not quite, a nuisance to them, because it is so frequently shocked. Others have a sense of musical values far above the average and yet others that nice sense of perfect proportioning to which reference has been made. All these gifts are likely, in this workaday world, to cause their owners a large amount of inconvenience to counterbalance against any pleasure their proper use may afford but, applied, they are of the greatest use to the community.

It is, perhaps fortunately, quite impossible to impart a sense of proportion. One has the gift or has it not. Granted, however, a tolerably acute sense of proportion, some preliminary experience or tuition will be necessary before it can be applied to garden design otherwise than empirically. Accumulated experience has taught even those whose eye for proportion is most rudimentary that an oblong picture is, speaking generally, more pleasant to look upon than a square one. Experience has gone further, it has suggested that a frame to a picture or a panel of such a shape, that, with the addition of another

similar frame along its longer side, will outline a frame of the same shape as the original (Fig. 3), and, of course, twice its size is a very satisfactory one for many subjects. The proportioning of the adjacent sides in such a frame will be as the square root of 2 is to 1, or, roughly, 7 : 5. Such proportioning will, even so, need modification according to the treatment to be accorded to the interior of the frame.

Let it be thought that we are getting a long way away from garden design, we will hasten to point out that since, except from an aeroplane, we can never see the design of a garden from anything approaching the viewpoint depicted on a plan, this test of proportioning cannot be applied directly to a garden plan. It is quite possible, however, from plan and elevation to set up a mathematically accurate perspective and to such perspective we can, if we wish, readily apply our tests. Better still, we can visualise, if we have adequately

represented on our sketch the weight of the varying features (mainly trees, shrubs and plants), the completed picture from the viewpoint in question.

The garden architect often makes, for his own satisfaction, a perspective such as this of some specially important feature but, in general, long experience of the work enables him inwardly to visualise the perspective he is seeking to obtain and to draw his plan in such a way as to obtain it, for it must be remembered that it is equally feasible to draw a perspective from a plan or to plan a particular feature from a perspective.

Given *carte-blanc* to provide a pleasing perspective from one given viewpoint—preferably on a little elevation—it would be the easiest matter possible for anyone with a knowledge of plants and the gift of composition to draw a plan which, properly carried out, would provide it. A blank canvas, however, the garden designer, whether amateur or professional, never has. He

FIG. 1.—A satisfactorily proportioned pool; its proportions correspond to those of the sunk garden, of which it is the principal feature.

FIG. 2.—An arrangement of flower beds in which each succeeding series follows the outlines of the complete garden. This is a quite good but by no means necessary arrangement.

has usually to provide his effect within defined limits, often in a very confined space. Nor is this his only or, indeed, his chief difficulty. He has to provide not one picture but many on the line of vista originally in mind and also so to unify the vista in question with the rest of the garden scheme that many other charming views may be

out, a rift, one may well be too narrow. It is impossible to give any rule for path widths, but it may safely be assumed that a turf path in any

position should be broader than a paved one in the same setting, while a gravel one should be narrower still.

REGULATING THE FLOWER BORDER

BY GERTRUDE JEKYLL, V.M.H.

BESIDES the obvious duties, such as staking, weeding, mulching when needed, and watering when drought threatens, there are many things that have to be seen to if an important flower border is to shew its best. At intervals during the summer we go through it attending to the various matters that are the urgencies of the moment. Now, in the end of July, beginning at one end where the flowers are blue and white and pale yellow, the Delphinium bloom going fast to seed is cut down to about $4\frac{1}{2}$ ft. from the ground. A strong plant of Clematis Flammula planted some years ago and now in full growth is trained so that it will rest on the cut Delphinium stalks and form

pumilus. Though not tall, it is of a heavy, sappy nature; when heavy rain comes it is apt to be thrown down in a lumpy way that is difficult to set right. We therefore support it with the branching tips of last year's pea sticks. Now, in looking at it from a few yards' distance, the group looks a little too regular and formal. This is corrected by shifting a few of the bits of spray, and as the plant has now hardened into maturity, some of the flower-laden growths are pulled a little out to give more play and freedom to the outline of the group. The same thing is done with a nearly adjoining group of Chrysanthemum maximum, as the mass of white Daisy flowers, all nearly of a height and covering 2 sq. yds. of

FIG. 3.— ABDE gives the outline generally approved as best proportioned for framing pictures of average subjects. Let AB be one side of the frame, the adjacent side to extend from B towards K. AC is marked off on the perpendicular from A equal to AB. BD is then made equal to BC. AFGE and BKJH are each double the size of ABDE and similarly proportioned.

obtained and that nowhere shall there be—to put it at its lowest—an entire lack of interest.

It has been remarked that a square picture or panel frame is unsatisfactory. To many it may seem strange, therefore, that square centre pieces are so much used in gardens. They are, in fact, employed to an even greater extent than circular or oval ones. The parallel actually is fallacious. From no conceivable viewpoint, except the air, does a square garden look square to the eye. The straight narrow rill now so popular represents a feature made picturesque by fore-shortening. This, it may be said, in passing, is a feature much overdone, since it is really effective only from one viewpoint; indeed, it often looks particularly banal and uninteresting when viewed from across its length.

There are a hundred and one details of proportioning which the novice can only decide by setting up a perspective, but the following hints may be of service. A very common and very pleasing feature in present day designs is a paved pool garden, the coping of the pool flush with the paving. In such a garden the proportioning of the pool should be the same as that of the garden itself if the planting be light, but, if heavy planting bound the garden, the edge of such planting should be taken to give the proportion. Fig. 1 will illustrate this point. The same point holds good with the arrangement of beds in a formal garden. The arrangement of the beds will be satisfactory if each successive sets of beds is proportional to the garden as in Fig. 2. The converse, however, is not true. A quite satisfactory arrangement of beds may be obtained which does not conform to this rule.

There is scarcely anything more important in the garden than the proportioning of the paths. In a small garden a 4 ft. path may be over wide. In grounds of some size, especially if broadly laid

THE FRAGRANT CLEMATIS FLAMMULA MAY BE TRAINED TO STOP GAPS.

a sheet of bloom over their place in September. Close by, that fine perennial Mullein, Verbascum Chaixi, now going out of bloom, is cut right down. It leaves rather gappy places at the base, but these are filled by plunging some pots of Hydrangea just in good bloom, and nothing is more useful for such a purpose. A little further along near the back of the border is a patch of the tall Helianthus orgyalis. If this was left to grow naturally it would shoot up to a height of 7 ft. to 9 ft. and bear a bunch of its pale yellow flowers at the top only. But we pull it down and peg it over some of the middle plants of the earlier summer, and it will develop flowers at every axil. Some of it is so tall that it nearly reaches to the front of the border and looks like some quite uncommon plant. A longish patch of Crested Tansy at the front edge, put there for the sake of its rich deep green foliage, must have the tips of its shoots pinched out for the third time; this keeps it to a foot in height and preserves the richly cut foliage in the best order. Just behind the Tansy is a long drift of Helenium

space, was too much of a solid patch. The border towards the middle of its length has a careful arrangement of Hollyhock, Dahlia, Camia and dark Snapdragon, and needs no present attention except that in one or two places where there was a gap a Dahlia stake has been altered to bring the plant forward to fill the empty place.

The biggest job was with a white Everlasting Pea of many years' growth and now a mass of heavy bloom. Its earlier regulation had not been taken in time, so that though it was supported with strong pea sticks it had not been properly divided and the growths separated. It was in one dense, heavy mass of bloom lying all together in one solid ridge. We drove in two stout Dahlia stakes about 5 ft. apart behind it and slit up a Phormium leaf in half-inch wide strips—a string would have cut the easily broken stems—and passed the band as nearly as might be half way, longitudinally through the mass of plant and pea stick, and drew it back carefully, separating the head part by hand, and made the ends fast to the stakes. Luckily, nothing was hurt, and

now the fine old Pea, instead of being a shapeless shell of crowded white, is suitably diffused and in good shape, and looks as if the newly released and separated blooms and branches were enjoying their restoration to air and light. The Pea is now, near the end of July, in full flower, but in another ten days will be going over. As it occupies a prominent place in the border and cannot be made to look well after blooming, a strong-growing hybrid Clematis planted just behind it will cover and hide it, and will make another sheet of bloom in the late summer. The Clematis is a natural hybrid that occurred in the garden: the parentage is evidently *C. vitalba* × *C. Davidiana*. The same cross has taken place in other gardens and, I believe, has been given a name, which at the moment I do not recall. Further in the border is a range of the purple-leaved Sage, whose quiet purple grey colouring is delightful with pink and purple flowers. It is being cut back, partly to allow of the dropping in of more Hydrangeas and also to promote its own young growth.

As to all these lesser cares of a flower border, some may say, "What a lot of fuss and trouble!" Yes it is, but then, *that is gardening!*

COLOUR EFFECTS IN THE FLOWER GARDEN

IT is difficult to give any absolute reason for the preference, but I think that others who give thought to using colour carefully will be likely to agree with me that one feels a disinclination to the placing in shady places of anything of very strong colour, and especially of any kind of red, and that in such places one would much rather have white or purple. Any opponent to this idea may quote the Foxglove, Rose Bay and Campion of the natural woody wilds, but I suggest that though it is pleasant to see these bright flowers, they do not promote that feeling of mystery which is one of the charms of woodland. In my own bit of copse a pure white Foxglove is rather largely grown, and beautiful if it is in the half light. Places are prepared for it in the winter among the Oaks and Birches; in some cases where there is an undergrowth of Bracken or Whortleberry, in others where there are those tangles of Bramble that the pheasants choose for nesting places. Two of the tall garden Campanulas are admitted to the wood, the white form of *C. macrantha* and the large-bellied purple *macrocarpa*; a lower one, *C. albanetolia*, is also used where the wood joins the garden. It is about 2ft. high and has a pyramidal form because of the taller central spike. It is suitable at the entrance to the wild because it is not a very common garden flower. For the same reason *C. persicifolia*, although in nature a true woodland plant, is not admitted to the wild ground; it is so familiar in the garden that it would give the impression of a garden plant gone astray. White flowers and foliage of deep glossy green are always pleasant together, and just now in the nearer garden ground there is a group of the white *Campanula macrantha* shooting up through several strong tufts of Alexandrian Laurel (*Ruscus racemosus*); the *Ruscus* just in the fresh deep green of its newly matured fronds.

I have no great liking in general for shrubs with variegated foliage, but in a wide flower border am glad to have a big bush of the gold Privet, the clear yellow of which is almost as telling as that of a flowering plant. Almost touching it and closely matching it in colour is a group of the fine perennial *Verbascum Chaxii*. The two, in close combination, form a splendid foil for some pale blue *Delphinium*. G. J.

SOME BULBS FOR AUGUST PLANTING

LEAVING garden Tulips on one side, which are more liable to suffer from the disease known as "fire" if planted too early, the earlier bulbs can be replanted the better, as a rule, will be the results, not only the following season, but in subsequent years. The softer the bulb the more it will shrink and lose substance if kept out of the ground. Really soft bulbs, such as *Erythroniums*, for instance, or Lilies, ought not to be kept out of the soil a day longer than is absolutely necessary.

The copious rains of July have made it certain that bulb planting will be practicable this month. Unfortunately, except on a very limited scale (and then by only the use of precious water), it was quite impracticable last year. Narcissi planting is a big subject and beyond the scope of an article such as this. [We shall hope to deal with Narcissi somewhat fully next week.—ED.] Leaving that important family on one side, the question then is: Which bulbs should be planted in August?

Among the most urgent, mention must be made of the Dog's Tooth Violets (*Erythronium*), so

are now a number of colour variations; some inclining rather to dull magenta shades, while flesh-colour and pure white are also represented. These are generally considered easier to grow than the American species but, in the writer's experience, this is not the case.

These American sorts are fairly numerous, as there are several species and a considerable number of varieties. The very best of these are probably *E. grandiflorum* Pink Beauty, with delicately poised flowers of a pretty pink shade, often zins across, and *E. californicum* White Beauty, which, quite distinct from the former as regards foliage, is very similar in everything but colour, as regards the flower. The flowers, of a charming creamy white shade, are seen when gathered to be orange at the base. The typical *E. californicum* is a pale yellow flowered species of considerable beauty. Other excellent kinds are *Hartwegii* and *Nuttallianum*, both yellow; *Hendersoni*, pinkish mauve with a deep crimson eye; *Johnsoni*, rose pink with a rich yellow zone, and *grandiflorum giganteum*, white with a brown zone, an easy and excellent plant.

Erythronium americanum, so common in North American woodland, has charming rather small yellow blossoms. Unfortunately it is not free to flower.

Fritillarias, very closely related to the true Lilies, should all be got into their permanent quarters as soon as possible. The Snakeshead or Meadow Fritillary, *Fritillaria meleagris*, is an indigenous species which grows freely in meadows in the Thames valley. The colour varies considerably, but is always either some more or less diluted shade of purple, heavily and quaintly chequered green or white, also green chequered. The white form has been so largely propagated that it is now as cheap as or cheaper than mixed varieties. It reproduces true to type from seed. If named varieties are wanted, *Orion* is a good deep coloured form and *Cassandra* a charming pale hued one having quite a silvery cast; both large. *Emperor* is a giant white with flowers more saucer shaped than usual and *Luna* a grand pure white sort. The Crown Imperials also belong to this family—*F. imperialis*—and should also be got

MOST BEAUTIFUL OF DOG'S TOOTH VIOLETS, ERYTHRONIUM PINK BEAUTY.

beautiful in woodland planting or on the half-shaded rockery. They all like a rather light compost quite free from fresh manure, but rich in decayed vegetable matter. They do not object to a light covering of fine Grasses or an overlating of Sedums or such like, which serve to mark their site and prevent their accidental disturbance. *Erythronium dens-canis* is the European species with, normally, flowers of a rather bluish-rose, but there

in as soon as possible. They dislike removal so should be planted in a position where they may remain for some years.

There are several very charming and unusual small species of *Fritillaria* which will delight the hearts of those who love the quaintly beautiful rather than the spectacular. Such are *F.F. pyrenaica*, *Thunbergii* and *coccinea*. *Pyrenaica* is olive green, mottled brown; *Thunbergii* green and

purple, with pretty grey foliage, and coccinea, almost scarlet.

Early-flowering bulbs of all kinds should be planted as soon as may be, including The Glory of the Snow, *Chionodoxa*, such early Irises

nor does the trouble end there, for it is quite possible for bulbous plants to flower quite well the first season after planting, but to fail subsequently because of unduly late planting. The beautiful dwarf blue Squill often used to edge flower beds, but

ONE OF THE EARLIEST BULBS TO FLOWER, IRIS RETICULATA VAR. CYANEA.

as *I. reticulata* and *Dantordiae*. Scillas, Grape Hyacinths, (*Muscari*), Crocuses and Snowdrops.

Of the Scillas, the Bluebells (*Scilla nutans*) and the nearly related Spanish Squills (*S. campanulata*) have rather soft bulbs and should on that account have preference. Late-planted Crocuses often seem to take little harm, but they are better planted none the less. Snowdrops, if kept out of the ground too long, not infrequently prove blind,

which may also be naturalised under trees and even in turf, is *Scilla sibirica*.

The Glory of the Snow, *Chionodoxa Lucilia*, provides masses of glorious blue flowers, when flower still is scarce in early spring. It is also excellent for naturalising. *C. gigantea* is less well known. The flowers are china blue, slightly paler in shade than with *Lucilia*, much larger and borne singly. *C. sardensis* is more like *Lucilia* in habit, but a darker blue.

COLOUR IN THE IRIS GARDEN

ONE of the excellent consequences of the growing popularity of Irises is that many gardeners are led to devote more attention to garden colour. Recent issues of THE GARDEN have contained many evidences of the search for suitable company for the Bearded Irises; here are a few notes for the amusement of those who, like the writer, enjoy playing the colour game with the wide range of Iris colour.

The most obvious associate of the Iris is the Lupin, and it is fortunate that just when the one flower is being transformed by the hybridist, the other should also be receiving increased attention. I wish someone who is familiar (as I am not) with the many varieties of Lupin now in commerce would study their colour and habit in relation to the best sorts of Iris, and would tell readers of THE GARDEN of their results. Here, for instance, is an elementary question: What is a satisfactory blue Lupin to grow in company with *Iris pallida dalmatica*, *Geranium ibericum platyphyllum* and Catmint? It may be that a sufficient answer is to be found in any packet of seed of the commonest blue *Lupinus polyphyllus*; yet I cannot help thinking that it is worth taking

the trouble to secure a selected form, and to propagate it, so that the group of plants may be uniform in height and colour. The very bluest Lupins are rather too blue to go with these pallida Irises; Prichard's beautiful *L. azureus*, which has a good deal of mauve in it, is about the right colour. This Lupin is also very good with that most free-flowering Iris, Sweet Lavender (*Bliss*; sent out by Wallace); and the deeper blue Lupin, Eureka (*Waterer*), can be added to this group, or planted with the purple *Geranium* and Catmint.

Other good Lupins of a purer blue that I have tried are *Waterer's Felicity* and *Admiration*. The former has the good quality of keeping its leaves in condition until late in the season, so that it can be put into a mixed border, if necessary, without its making an untidy litter; the ordinary *L. polyphyllus* generally becomes an unsightly ruin soon after flowering. The herbaceous Lupin which, so far as I know, keeps its leaves better than any other is Barr's variety *Nelly* (Barr, and *Waterer*). This is a white sort with a touch of clear mauve, and associates beautifully with Sweet Rocket and *Thalictrum aquilegifolium*, and with *Iris Alcazar*. I presume that this is one of the sorts with some Tree Lupin blood in it.

The clear yellow herbaceous *Lupin Sunshine* (*Waterer*) takes up the colour of the yellow Tree Lupin and of *Iris Flavescens*, and is much fresher in colour than the other herbaceous yellow sorts that I have tried; those with a tinge of ochre in them are not satisfactory.

There is, I think, a tendency to get the colour of the new Lupins too complicated and muddled. The so-called "shot" effects, now so easily obtained in Lupins, are not often a success in this flower. Can anyone tell me of a silvery-leaved Tree Lupin of really good constitution and effective flower? I want one which combines the good qualities of *argenteus* and *arboreus*.

But to return to Irises. I had long been puzzled to find the right foils for the subtle colour of Irises *Prosper Laugier* and *Jaquiniana*. *Iris Flavescens* and the pale yellow Tree Lupin used to be the best I could do; but this year I found what seems to me a much better arrangement. Instead of the clear pale yellow, which in bright light kills the sombre smoky colour of *Prosper Laugier*, I put the cool washed-out rose of *Deutzia elegantissima*, and backed that with *Rosa rubrifolia*. *Iris Dawn*, which is very pale yellow in effect, took the place of *I. Flavescens*. I feel sure that if you try *Prosper Laugier* with this *Deutzia* you will agree that the Iris has a good chance of showing off its rare, subtly compounded colour.

There is sometimes a difficulty in finding the right sort of pink flower to relieve the blues and yellows of the Iris garden. China Roses are good, and so are the cool pink—not the salmon pink—later-flowering Weigelas. The pink Lupins, *Pyrethrums*, *Thrifts* and *Pinks* and the pink *Columbines* are all available, and I think the pink *Deutzias*, such as the beautiful one I have mentioned, might well be more commonly used. A very good white *Deutzia*, by the way, is *D. Wilsoni*, certainly one of the most beautiful of its race.

Someone suggested the other day in these columns that Irises would look well with Azaleas, but I confess this does not appeal to me. The associations of the two families are so different, for one thing: the Azalea seems to call for half-shadowed woodland spaces (such as one sees it in at South Lodge), whereas the Irises remind one rather of their own parents, the species that one has seen growing wild on hot hillsides in the South. And there is the further point, apart from all questions of horticulture, that the Azalea's characteristic range of colour includes many oranges and flaming reds that are too warm and, so to speak, too insistent to associate well with the Iris colours. That, at least, is how it strikes me: I admit that I have not actually tried the planting suggested. No! for this particular purpose I shall stick to the cooler range of colour. The shrubs that get admitted into my Iris garden will be such as *Solanum crispum*, *Abutilon vitifolium*, *Rosa Willmottiae*, *Honeysuckles*, and the early Clematises, e.g., *C.C. montana*, *pi. rubens*, *Spooneri* and *Spooneri rosea*, *Fair Rosamond* and *Mrs. Cholmondeley*. Try *Rosa Hugonis* with *Solomon's Seal* and *Dielytra*, or with *Rosemary*, *Cytisus praecox*, and blue *Columbines*.

But I see I have got out of the Iris garden altogether, so I must stop. A PAINTER.

FORTHCOMING EVENTS.

August 14.—United Horticultural Benefit and Provident Society's Meeting.

August 15.—Clay Cross Horticultural Society's Show.

August 16.—Derbyshire Agricultural and Horticultural Society's Annual Exhibition (two days).

August 18.—Royal Horticultural Society of Perthshire Exhibition (two days). Eastbourne Horticultural Society's Meeting.

PLANTS FOR A SMALL MORaine GARDEN

(Continued from page 375.)

SILENE ELIZABETHÆ.—This uncommon Silene has not been a success. One or two plants raised from seed, and also purchased plants, never seemed to become properly established, although living through two or three winters, and eventually died out without flowering. *Silene Hookeri.*—This, the outstanding beauty of the family, has not been tried. It seems to be very rarely offered for sale, and when it is, is usually sold out when applied for. *S. acaulis*, *S. a. excapa* and *S. a. alba.*—The dwarf green cushions keep compact on the moraine and the plants flourish, but if they flower at all it is very sparingly. *S. acaulis alba* flowered fairly well in May of this year, and seems to do better in this respect than the types, which rarely flower at all. Last year, however, one of the plants had a few flowers on in August in a position away from the moraine facing north, where it is being tried. *S. laciniata Purpusii.*—This species with its brilliant red flowers, would be most useful, flowering late when flowering plants are badly needed. Unfortunately, it has been found difficult to keep with me. The damp and frost of the winters set in rot in the somewhat woody stems at about the ground level. It seems to flourish in a friend's garden only a short distance away in a more sheltered position, having come up annually for the past three or four years. *S. alpestris.*—This dainty white-flowered species is only too much at home. Tending to run into other plants, it has to be placed in more unrestricted quarters. The double form *S. alpestris fl. pl.* might prove more suitable and last longer in flower for those who like double forms; that is if it does not revert back to the type, as it seems to have a tendency to do in one or two gardens in which I have seen it.

Soldanella pyrolifolia is probably one that Farrer acquired on one of his expeditions in the Eastern Alps, and one which may have rewarded him with its pretty flowers better than other members of this dainty flowering family do in a good many of our gardens. *S. alpina* and *S. pusilla* appreciated moraine conditions so far as to become well established, but as they never flowered in the fully exposed position they were tried in a more shady situation, with the result that *S. alpina* has flowered for the last two or three years, but *S. pusilla* and *S. minima* have failed to flower as yet. *S. montana* is a much more vigorous plant than those previously mentioned, and given suitable conditions with other soil than the moraine usually provides flowers quite freely.

Thlaspi limosellatolium.—This is another rare species which does not appear to be found in catalogues. It is a family, too, that is very rarely represented in gardens. Seeds were taken by me

of what is probably *Thlaspi rotundifolium* under the Matterhorn two years ago, and some of the plants raised appear to be quite healthy, but have not flowered yet. *T. Keeneri* has very dark green rosettes. Seedlings planted recently are growing away well and, "winter permitting," should flower next summer.

Veronica canescens.—This appreciated the conditions too well. It was moved to other parts of the garden, where a little of it still exists, but it has almost been lost owing to the damp winters and very dry springs, especially the latter, as it depends on a certain amount of moisture for its revival, and once nicely set going it will run a considerable distance in a season. I am inclined

A BEAUTIFUL LAVENDER-COLOURED ALPINE, SOLDANELLA ALPINA.

to think it is hardly worth its place, the pale blue flowers not being particularly interesting.

Viola censis has not been tried by me, nor have any of the *Violas* on the moraine. It is possible that some lovely high "Fell" pasture forms of *Viola lutea* may be tried.

Wahlenbergia punilio.—This lovely dwarf pale Bluebell flower is very happy and well worth its place, and once established stands the winter exposure without any protection. The only drawback is that the flowers are all out and over in a week or less, especially if it is dry, hot weather at the time. *W. dalmatica* and *W. tenuifolia* are interesting and in this position very free flowering. *W. serpyllifolia major* seems quite easy with its large lovely "Purple Bells" very freely produced but, unfortunately, short-lived. *W. Vinciflora* is somewhat different to the others, the delicate blue flowers being thrown out on wiry, pendulous stems. It is a continuous flowerer

and especially lovely in an overhanging position. Unfortunately it is liable to be killed off in the winter months, although plants have gone through two or three winters in the somewhat bleak climate of these parts.

Wahlenbergia punilio completes Mr. Reginald Farrer's "fifty" plants for the moraine. A few notes of other families that have been tried may be of interest, some of which have only come into our gardens since his list was published.

Acantholimon glumaceum and *A. venustum.*—Both plants have fine hard green cushions, the latter greyer and very prickly. Both are acquisitions and appear to prosper in an exposed position. The flowers of *venustum*, which are clear rosy pink thrown well out from the cushion in racemes, are especially beautiful.

Of the Sandworts, *Arenaria cæspitosa aurea*, with its bright yellow foliage, provides a very good colour contrast and brightens the moraine up in the "off" season. It is much less aggressive than the rampant *A. cæpitosa*, which should not be included on any account. It also provides a good position for a few dwarf Crocuses, the flowers easily penetrating the somewhat loose sand. *A. purpurascens.*—This Spanish species, with its close foliage and lilac flowers, is useful and easy to keep to its place. *A. tetraquetra* forms a neat hard tuft of somewhat peculiar foliage, with white flowers, interesting without being specially striking. *A. verna.*—This beautiful native is well worth a place, with its deep green grassy foliage and dainty white star flowers and should be planted in a limy position for preference. Beware of *A. balearica*, which will run over everything and what is more, very few plants can push through it; it is a thorough nuisance and once established (quite easy in moraine), it will be a difficult matter dislodging it.

Armeria cæspitosa, a charming dwarf Thrift from the mountains of Southern Spain, with its compact rosetted clumps and pale pink flowers, is an indispensable. I appear to have two forms, one with dark green foliage, which is usually covered with flowers, the other with finer and brighter green leaves and which has not flowered anything like so freely.

Daphne petraea.—This dwarf and beautiful *Daphne*, from a restricted portion of the Maritime Alps, appears to be "settling" down and at present looks quite healthy, but it has only flowered sparingly; I am hoping it will flower more freely when thoroughly established. The moraine seemed to me to be a suitable place for this very dwarf shrub and I may say that a few other "small" shrubs have been included, some of which will be mentioned later, all evergreen and mostly with darker foliage than the plants and thus providing some colour contrasts.

The more compact *Erodiums* or "Crane's Bills" provide beautiful foliage plants, with *Geranium*-like flowers, which in some of the species are continuous for most of the summer if kept from seeding. Among the best are *E. chrysanthum*, with pale yellow flowers. *E. corsicum*, a very pretty compact free-flowering species. *E. Richardii*, a dwarf running plant with dainty white upstanding short-stemmed flowers. A variety with rosy pink flowers was seen at the Edinburgh Botanic Gardens last September, which is a valuable addition. *E. supracanum* is one of the prettiest, with its lovely "lenny" foliage and rosy pink flowers freely produced.

Of the *Gentian* family only three have been tried on the moraine. *G. acaulis*, which did quite well, but as it does even better in more ordinary conditions and flowers very freely, it has been moved from the moraine altogether. *G. excisa*, tried on two occasions, but never got over the effects of winter rain and frost, the continuous disturbance through

frost and thaw causing the plants to rot off near the crown.

G. verna.—This lovely native does best with me on the moraine, two plants bearing seventeen and twenty-five to thirty flowers last May; the larger flowered plant had glass protection above for a good part of the winter and not only flowered better than the one unprotected, but had larger and greener foliage and much larger flowers. I have had as many as seventy flowers on the larger clump, but owing to the moraine in the portion in which it was planted (the deepest portion), not having been properly consolidated, it had to be disturbed and in doing this it was found that the thread-like rootlets penetrated down to the sand in the bottom and were about 3ft. in length, partially suspended in mid air owing to some of the filling having "settled" away. This

disturbance checked the plant, but it seems to be recovering. It is quite possible to raise small plants from the flower rosettes of this *Gentian*. Some time ago some wild collected flowers were placed in a saucer with damp sand in the greenhouse so as to keep them in flower for a time, but my mother promptly pinched the flowers off and most of them rooted in a very short time.

T. ASHTON LOFTHOUSE.
(To be continued.)

THE GOLDEN BLOSSOMS OF FREMONTIA CALIFORNICA.

CORRESPONDENCE

A FINE POLYANTHIA ROSE.

THERE is a little bed on the lawn, containing eight plants arranged in a circle—plants of the wonderful dwarf Polyantha Rose *Ellen Poulsen*. Everyone who looks out of the window or walks round the garden notices it first of all. The vivid hue and gorgeous mass of blossom compel them to do so. Peerless and irresistible, it is the most intense and joyful spot in the whole length and breadth of the garden. I suppose that it has some leaves—indeed, I know that it has—but all of which one is conscious in the way of green about it is the turf that surrounds the bed. Its height averages about 18ins., and it is remarkable how "even" the growth is; while the flowers . . . mass upon mass of cherry rose, large and full and free. The colour is one that at once penetrates and compels attention and satisfies the eye.—CROYDON.

ROMNEYA COULTERI GROWING THROUGH A WALL.

THE photograph was taken in July at Perriton Mead, near Minehead, the property of Mr. C. S. Orwin of Balliol College, Director of the Institute for Research in Agricultural Economics

at Oxford. Originally planted five years ago 3ft. from the slate and rough earth wall, which is 21ins. wide, in 1921 shoots appeared at a lower level through the wall; and this year there are on that side about three dozen such shoots, 4ft. to 5ft. long, with blossoms 7ins. across. But a but-tress immediately in front of the original plant, which faces east, caused the penetration of the wall in a south-easterly and downward direction. A somewhat similar instance, but on a smaller scale,

of the Californian Poppy sending shoots through a wall appears in the charming garden of my friend, Mr. N. G. Hadden at West Porlock in the same district of Somerset.

At the entrance to Perriton Mead I was allowed by the gardener, Mr. Parkman, to inspect two fine and tall shrubs of *Fremontia californica*, a brilliant

yellow flowered Californian plant rarely seen in this country. Like the *Romneya* in its land of origin it is interesting as being the only known example of its genus. It belongs to the Sterculiacee, one of the Malvales group of families. The deep yellow blossoms are 2ins. or more in diameter; the egg-shaped fruit is densely clothed with yellowish hair, and the lobed leaves, often smaller than the flowers, are thickly coated beneath with short grey stellate hairs, which give them an ashen appearance.—H. STUART THOMPSON.

"AFFECTED" GARDENS.

I AM sure all lovers of flowers for their own sake must agree with Anne Amateur's letter on this subject (July 8 issue, page 333). If gardeners would study the welfare of each individual plant, giving it the position that is most suited to its taste and follow, in the general design of the garden, the natural suggestion of the soil—making paths take the course that would be followed by a stream (the line of least resistance); and studying the wild shrubs and plants of the neighbourhood as a guidance in selecting what garden varieties to grow, we should see more beauty and less vulgarity in some of the gardens laid out during the last ten or fifteen years. That gardens can look affected is bad enough, but that flowers should be forced to look vulgar is unpardonable. I have seen lately several fairly new French villa gardens and anything more sad in the way of distorting and insulting Nature I hope never to see. One is on the side of a hill and consists of small round beds made level with minute paths and surrounded with narrow paths of stone; each bed contains a Turner's Crimson Rambler Rose as a centrepiece and is encircled by a row of crimson *Godetia*, after which each bed

ROMNEYA COULTERI GROWING RIGHT THROUGH A GARDEN WALL.

has a border of highly coloured annuals. At one corner there is a modern, most grotesque well-head, large enough for the courtyard of a chalet, with wrought-iron top and rope complete (a standard pipe from the waterworks being within sight). On the ledge by the well-head are two life-sized china animals, a white cat and a black and tan terrier. The whole garden is partially enclosed by a belt of shrubs, mostly variegated; I suppose the whole atrocity occupies about half an acre.

Half a mile from this distressing sight there is an old house standing in a garden of about the same size as the other and surrounded by a high wall. This, mercifully, has been bought by a woman with garden knowledge and, still more important, a love of nature. Finding it in a neglected state she has cleared away the useless old Currant bushes and ugly stunted shrubs, keeping a few old fruit trees and the lovely old vines on the stone west wall. In the flower beds that are in half shade—that most blessed of positions for most plants in a temperate climate—Carnations and *Alstroemeria* revel in the warm sandy soil, Sweet Peas grow 7ft. high without manure, and annuals sow themselves between the larger plants, the whole giving a blessed feeling of tranquillity, sweetness and simplicity. There is nothing new in this. I suppose there have always been these contrasts between those who feel with and, naturally, copy Nature and those who misunderstand and contort her. But there are also those who follow a fashion blindly and unthinkingly, and it is they usually who produce the effect of affectation when they try to design a new garden or alter one of mature growth, and for them, because they sin unconsciously, there is hope. The modern craze for stone paths, stone walls and rock gardens is a terrible pitfall to many. I have in my mind a small garden that, being in a peaceful valley not far from the gas works and the railway, has the battlemented appearance of being constructed to resist a determined siege at any moment of the day or night.

I feel sure that the majority of affected gardens have been designed on paper and constructed as a whole at one time, this doing away with the pleasure of discovering new possibilities as the owner becomes more intimate with the garden through living in it. This rush for completion is, of course, the spirit of the age, and is hard to combat, but defeats itself as far as gardens are concerned, for nature is slow and a garden must grow; it cannot be made.—*ETHEL CASE, Sarum.*

FLAVOUR IN MUSHROOMS.

IN this strange autumnal July, with a frost in the small hours of its last day, even here in the Garden of England I have for some days past been engaging in my annual "Feast of Mushrooms"—quite a month earlier than usual and have had enough to satisfy even *me* (about a pound a day all to myself!).

I have this season, for the first time, had an opportunity of comparing the flavour of wild field Mushrooms with those grown from cultivated spawn in bricks. The latter were obtained from those celebrated seedsmen, "Messrs. Swank and Selfpraise"—shall I call them?—(who finds the cap fits may wear it). The first and largest Mushrooms came from the turf Mushroom pits, where the cultivated spawn had been inserted, and they are continuing to yield a fair crop. A day or two later I had some smaller wild field Mushrooms, and the third cooking contained some of each. I must, as a connoisseur of Mushrooms, unhesitatingly record my verdict, that there is absolutely no doubt that the wild ones are far and away superior in flavour to those grown from Messrs. S. and S.'s bricks. The latter, though larger, are lacking in

flavour and also have far too much tasteless and tough "white kid glove" on the top towards the centre, and scarcely any gills underneath near the stalks, while the wild Mushrooms from the meadow have much thinner white integument and more depth of gills and are vastly superior in flavour.

Perhaps while writing on this topic I may note that some old writer (I think it is Evelyn, but am not quite sure), notes that "donkeys' dung is the best for growing Mushrooms," so possibly some of the credit is due to my donkey "Sally," who "thinks she is a person and doesn't know she is only a donkey," as a dear little niece of Mrs. Busy Bee once explained to the other children when visiting us at Blackbird Bungalow.—*ANNE AMATEUR.*

[If "Anne Amateur" would spawn some of her pasture from the source she mentions and would compare the produce with the wild field Mushrooms, she might probably find less difference than she does at present though, unquestionably, some of the finest flavoured (red stalked) Mushrooms seen to be cultivated.—*ED.*]

A "PALM" IN FLOWER.

I ENCLOSE a photograph of *Cordyline australis* in flower here on June 21. The tree is now 17ft. high. I have had it about fourteen or fifteen years and it has never flowered before. That it

CORDYLINAE AUSTRALIS FLOWERING IN KENT.

has done so this year is, I presume, the result of the roasting it got last summer? It is well sheltered from north-east winds by a Lime tree. A Persimmon tree here has also set several fruits for the first time.—*A. C. BORTON.*

A REMARKABLE ANEMONE.

A WELL flowered specimen of *Anemone glaucifolia* from the Edinburgh Royal Botanic Garden was exhibited at the monthly meeting of the Royal Caledonian Horticultural Society on August 1, and was awarded a cultural certificate. This Chinese species attains a height similar to that of *A. japonica*. The flowers which are pale blue are somewhat globular in shape. The leaves are much serrated, reminding one of those of *Francoa ramosa*. If one may judge by this plant, the specific name is not very felicitous,

as the colouring of the foliage is more bronze-like than glaucous. It is believed to be the first specimen of this species to be flowered north of the Tweed.—*CHARLES COMFORT.*

[This is the plant which recently received a first-class certificate from the Royal Horticultural Society as *A. glaucophylla*. It was figured in THE GARDEN for July 8, page 331. The certificated name, as altogether of Greek derivation, certainly seems better.—*ED.*]

GARDENING OF THE WEEK

FOR SOUTHERN GARDENS.

The Kitchen Garden.

Onions.—Seed may be sown this month to serve two purposes, if necessary. First, to provide suitable material for salads and useful small bulbs for kitchen use during autumn and winter; and, secondly, to provide bulbs for using the following summer and autumn. For the former purpose space the drills about 10ins. or 12ins. apart, and this will also be enough for the latter if transplanting is done the following February and March, otherwise the drills should be 15ins. apart. If sowing is done where the crop has to mature, the plot should be prepared accordingly. Growers who have to deal with cold soils and find that the spring-sown crop cannot be finished and ripened up as it should, ought to make the best possible use of the advantages offered by autumn sowing.

Leeks and Celery of early plantings should be attended to as required and according to the purpose in view. Whatever method of blanching or earthing up is practised, see that the plants are in an even state of moisture before carrying out the work.

The Flower Garden.

Amaryllis Belladonna, more popularly known as the Belladonna Lily, is one of the most beautiful of the hardy flowering bulbs. Planting can be carried out now and until the early autumn, but, to secure good root establishment before winter sets in, the sooner planting is done the better. Choose a position having a southerly aspect on house, wall or building, and see that it is a well drained one. Among the bottom layers of soil incorporate old manure, and use some coarse sand and gritty compost around the bulbs when planting.

Dahlias.—These having made and still making rapid growth call for attention in staking and tying to give them the necessary support during their flowering season. Do not allow the plants to be too crowded with shoots, removing all weaklings, particularly from the centre of the plants. Should earwigs prove troublesome, invert some small pots on the tops of the stakes, having first placed a little moss in the bottom of each one. In this way the regular destruction of the earwigs as they congregate among the moss will soon clear them. Another way of trapping them is to place Broad Bean stalks cut into suitable lengths among the plants, into which the earwigs readily enter and can be destroyed.

Fruit Under Glass.

Strawberries.—The potting of those intended for early work under glass, if not already seen to, should be pushed forward as rapidly as possible, for by the end of the month even the late batches should be in their fruiting quarters if it can be managed. The main compost for the final potting must be good loam, and to each cartload of this may be added three barrowloads of dried horse droppings, one of old soot and one of wood-ash. Bone-meal may be added if desired at the rate of a bushel to the cartload, or a coarser bone manure be used by sprinkling a thin layer above the drainage of each fruiting pot. Firm potting is absolutely essential, and the plants must be regularly dealt with as regards syringing and watering according to weather conditions. Should the weather be very hot and dry when potting is in progress, the plants may, for a couple of days, be allowed to recuperate a little in a somewhat sheltered place, but they must then be placed in full sun and light on a firm ash or gravel bottom and left there until the time comes for removing them to their winter quarters.

Early Peach Houses.—Where time can be spared for the work it is indeed well spent to give attention to the early fruiting trees of Peaches and Nectarines as they are cleared of their fruits. Should heavy crops have been carried and the trees be not too gross in growth, continue to water the borders regularly with copious supplies of liquid manure, and thus assist the trees to build up good fruiting wood for another season. Cut out all old fruiting wood that can be spared so that light and air may have a freer access for the necessary ripening of the new wood. Should red spider have obtained a footing, thoroughly drench the trees several times with a good insecticide until it is got rid of, after which one good syringing each evening with clear water will keep the trees in a healthy state.

The Hardy Fruit Garden.

Early Apples, such as Gladstone and Irish Peach, are practically of no value for gathering and storing, but require to be used as ready, direct from the trees. It will be necessary to give protection from birds, or the damage they commence will soon be made much worse by the insects following them.

Aibury Park Gardens, Guildford.

FOR NORTHERN GARDENS.

The Kitchen Garden.

Beet.—Do not allow the early sown globe-shaped sorts to remain in the ground after they have attained a good size, as they readily become coarse and stringy. Lift and store in sand in a cool position, when they will be found to keep in usable condition for a lengthy period. Keep the hoe going among later-sown sorts.

Potatoes.—When lifting early sorts, tubers of the size suitable for seed should be laid aside and placed in shallow boxes. Allow them thoroughly to ripen before finally storing in an airy loft or shed.

Turnips.—Make a final sowing of a quick maturing sort on an early border. Sow thinly and encourage a quick growth so that nice tender roots may be had during late autumn.

Saladings.—Sow regularly quantities of Mustard and Cress, and Radishes both of the long-rooted and turnip-rooted sorts. Encourage Lettuce by copious waterings of liquid manure and tie up the Cos varieties to assist in hearting.

Onions.—During the next week sowings should be made in sheltered quarters for spring and early summer use. One of the essentials in wintering this crop is that the ground be well drained. To sow on ground that is damp or sour is to court failure. More especially is this so in northern gardens, where heavy rains and severe frosts prevail during the winter and spring months. Give the surface of the seed-bed a generous dressing of wood-ashes, working it well in with the rake. Sow in lines 12 ins. apart, using the Tripoli type for the purpose.

Parsley.—When thinning late sowings a quantity of the young plants should be pricked out in a spare frame for winter supplies.

The Hardy Fruit Garden.

Apple Trees.—When summer pruning it is essential that the operator know the difference between ordinary growths and fruit-bearing spurs, meaning the short, sturdy growths which terminate with a fruit-bud. It is noticeable that many varieties, such as Worcester Pearmain and Irish Peach, produce a goodly portion of their crop on growths of this description. Naturally, the indiscriminate removal of these causes disappointment next season. Sufficient extension wood should be retained on all young trees, and any necessary thinning of fruits have attention. Where the trees are suffering from attacks of aphid they should be thoroughly syringed for a few evenings, using the garden engine for this purpose.

Fruit Under Glass.

Melons.—Plants growing in frames still require careful treatment, particularly so as the fruits approach maturity; neglect in this respect often causing loss of flavour. Close the frames early in the afternoon, and reduce the moist conditions hitherto allowed. Thin out any superfluous foliage that is likely to prevent the sunlight reaching the fruit. As the fruit begins to ripen leave a little air on, both day and night.

Grapes.—In vineries where the berries are colouring, additional air should be allowed at both top and bottom, reducing it considerably

at night according to weather conditions. All unnecessary lateral growths should be removed, so that the maximum of light and air may reach the fruiting wood.

The Flower Garden.

Climbing Plants growing against walls should be regularly attended to as regards water, as, owing to their position, even the heaviest rains fail to reach their roots. To assist growth liquid manure should also be given, while a moisture-retaining mulch of short litter will also be beneficial. In dry situations red spider is often troublesome, but may be checked in time by judicious syringings with a reliable insecticide.

Daffodils.—Where the bulbs of these were lifted after flowering, opportunity may be taken now to have the bulbs planted in their flowering quarters in woodland or shrubbery.

(Gardener to Sir Henry H. Houldsworth, Bart.),
Coodham, Kilmarnock

GREENHOUSE AND CONSERVATORY.

Freesias.—If a batch is required to flower at Christmas, they should be potted up without further delay, for Freesias cannot be hurried and must have cool treatment at all stages of their cultivation. It is true they may be gently forced if required for a special purpose, but it is always at the expense of the plants and also the quality of the flowers. Freesias enjoy a light rich compost, some dried cow manure rubbed down fine, or old mushroom-bed manure is excellent to add to the potting compost. They are best grown in 5 in. or 6 in. pots, putting ten to fifteen corms in a pot. The pots should then be stood in a cold frame. They should be well watered and then heavily shaded until they show signs of growth. The shading keeps them moist and does away with the need of frequent watering, always an evil in the case of bulbous and tuberous-rooted plants until they have made a quantity of roots. Some cultivators cover the pots with ashes or leaf-soil, but I do not advise this method, as the young growths are often weak and drawn if by some chance the covering material is not removed in time. Some support is essential before the growths fall over, for if this happens they never quite recover from it. The many beautiful coloured varieties are becoming increasingly popular, and require the same treatment accorded Freesia refracta and its varieties. Freesias raised from seed sown during March should now have well filled their pots with roots, and will benefit by frequent applications of diluted liquid manure and weak soot water.

Lachenalias form another beautiful genus of South African bulbs worthy of more general cultivation. They should be potted up some time this month. Where home-grown stock is available the largest bulbs should be sorted out for potting. Smaller bulbs should be placed in pans or boxes, and if well grown should make good flowering bulbs for next year. The larger bulbs should be potted in 48-sized pots, placing six or eight bulbs in a pot. They enjoy the same cultural conditions as advised for Freesias, doing well in cold frames until such time as their flower-spikes appear, when they may be removed to a cool, airy greenhouse. During February and March special care is required in applying ventilation, as cold draughts disfigure and injure the foliage. Although there are quite a number of species, very few of them are in cultivation, the most popular and useful being *L. tricolor* and its varieties, also *L. pendula* and *L. Nelsoni*, a garden hybrid. The latter is very beautiful and probably the most popular with the average cultivator.

Bulbs for Early Forcing, such as Roman Hyacinths, Paper White Narcissus and Duc van Thol Tulip should be potted up or placed in boxes some time this month. Success in forcing such plants depends very largely on their being well rooted, hence the importance of early potting, so that they have plenty of time to develop a good root system. Where quantities of Roman Hyacinths and Tulips are required for decorative work it is just as well to put the bulbs into small boxes. The flowers can then be cut in quantity, or the bulbs may be lifted from the boxes as they come into flower and used for filling suitable receptacles for use in the dwelling-house. If pots are used, 5 in. is large enough for the Hyacinths and Tulips, putting five bulbs in a pot; while Paper White Narcissus will require 7 in. pots. Stand the pots at the bottom of a wall and cover with ashes that have been exposed to the weather for some time, or leaf-soil may be used for the purpose. When growth begins to appear through

the top of the soil the plants should be removed from the covering material and stood in a cold frame, one with a north aspect being best for this purpose until such time as they are required for forcing.

Lilium candidum.—The Madonna Lily can be successfully grown in pots for the cool conservatory, but it must be potted some time during August, for this Lily commences to make its growth soon after flowering. One good bulb should be put into a 7 in. pot. As this is not a stem-rooting Lily, it is not necessary to leave room for top-dressing. Good medium loam with the addition of a little leaf-soil and sand should be used; also a sprinkling of lime or basic slag, as this Lily is a lime lover. Stand the pots in a cold frame, and give plenty of air at all times; in fact, cool treatment right throughout is the secret of success in growing *L. candidum* in pots. It is, of course, essential to start with healthy bulbs.

Royal Botanic Gardens, Kew.

J. COULTS.

Alpines at the Grand St. Bernard, Switzerland

"BUT now you have come so far," said genial Professor Chodet in the midst of his dissection of Colchicum bulbs at the Garden Lunca, "you should really go on to the Hospice of the Grand St. Bernard and taste the hospitality of the monks. Only six hours from here by the post cart."

And so, at 7.0 a.m. I registered myself as a parcel and started with the letters for that famous Hospice—and a grimmer, more desolate road I have never seen. Vegetation was scant, though *Saxifraga caesia* was in abundance at sides of the road and so were the faded leaves of *Gentiana lutea*, and so were the faded leaves of *Gentiana lutea*, and so were the faded leaves of *Gentiana lutea*, and so were the faded leaves of *Gentiana lutea*, I found, near the river, *Gentiana germanica* of an ugly red mauve.

Soon we were beyond the snow line. No more trees, nothing but grim rocks and thistles. A peasant girl was busy cutting the latter and carrying them home in sacks to boil down for the pigs. The postman told me that all through the winter he goes on skis thrice weekly to the monastery, as there is no other way of reaching it. Even in August the little valleys are full of snow.

Once arrived at the Hospice all sense of loneliness vanished in the clamour of the dogs of St. Bernard and the chatter of some hundreds of Italian tourists who had crossed the frontier.

After seeing the chapel and library, I was taken to the Prior's garden, which he and a "brother" amuse themselves by making! It was really pathetic! After climbing like a goat over and round boulders for two or three hundred feet one comes upon a little ledge with pitiless rocks on three sides. Here is a small bed of earth, carried up, a basketful at a time, by these two patient monks, and a few pockets of soil, and one can just get round the tiny path. The plants have been collected on the mountains in the near neighbourhood and must be of an astounding hardness to survive in such a severe climate, which kills any man who stays at the Hospice more than ten years, even though he be of a mountain race, which is a *some qualification* of the brotherhood. Here were growing *Viscaria alpinum* (rose), *Doronicum grandiflorum*, *Potentilla grandiflora*, *Achillea nana* (hybrid, very pretty), *Geum reptans* (yellow), one or two rare specimens of miniature Willows (*Salix aurita* & *reticulata*). The exquisite little cushions of *Androsace alpina* (jewelled with pink and white), and the "heavenly" blue *Myosotis pyrenaica* were side by side.

They and the beautiful *Hugueninia lancifolia* (yellow) were the most attractive flowers out, but *Cerastium arvense* and *Silene exscapa* were

lovely too. Delphinium elatum was over, but Papaver rhæticum showed a few flowers. Geranium rivulare was also over, but Aconitum paniculatum was in purple bloom, and Erigeron uniflorus.

A hundred feet or so higher up the "brother" had made a tiny bed in the form of his initials, S. B., edged with rocks, and here were growing happily Primula farinosa, Gentiana imbricata and the beautiful Campanula Scheuchzeri, such a glorified edition of our Harebell, but in richer colouring.

Lower down, near the gloomy little rock-bound lake, the white Ranunculus was to be found and among the stones at side of road were Hieracium glanduliferum, Leucanthemum alpinum, Achillea moschata, Silene rupestris and Saxifraga stellaris.

And there, said my guide, waving his arm across the guarded frontier towards Savoy, lies "Paradiso, full—full of the most wonderful flowers and strictly preserved as a hunting domain."

To reach the Grand St. Bernard one takes the train from Martigny (near Lac Lemani), as far as it goes. Then one hires a vehicle which in six hours takes one to Bourg St. Pierre, where the famous alpine garden La Linnee was founded by M. Corréon, and which contains 25,000 different plants. A few Gentians, Aconites and the beautiful Pyrenean Valerian are all that can be seen in August, but the place is a liberal education to a rock gardener. A somewhat comfortable night in a very old Swiss Inn and an early start either on foot or by the post cart as a parcel! The more comfortable way is by motor.

The prospect of a night spent in that gloomy place, even with three hundred Italian trippers, did not attract me and I gladly accepted the offer of a seat in a luxurious Mercedes car as far as Martigny. The most wonderful drive. To descend 8,000 ft. in two hours! From bitter cold to the intense heat. From glaciers to grapes. A. M. M.

that it shall be a merry one. I should be the last to join issue with advocates of deep and thorough cultivation for this crop, since I look upon deep friability, associated with proper firmness, as the best preventive of mildew either in a dry or a wet season, but I am ever ready to question the wisdom of those who advise, and personally use, excessively heavy dressings of natural manure.

There is no doubt that heavy manuring encourages big plants with large leaves, but these latter are not nearly as valuable as those perhaps only three-quarters of their size but of deeper colour and infinitely finer texture, and the reason is simply that the smaller, harder foliage has a finer power of performing essential functions. As supplementary to the best possible mechanical culture I recommend moderate quantities of natural manure and concentrated fertilisers in the spring, after the first crop has been harvested, with basic slag in the second and third autumns on soils where it is known from previous experience to be advantageous. One secures thus a thriffter plant with superior crowns, and it is on these that we must depend for our yields of Strawberries.

If it is compulsory to plant immediately after working, special attention must be directed towards firming in advance of planting, but when an interval of round about three weeks can elapse, as it ought always to do, between the operations all land, except that of very light nature, will have settled down naturally to the desirable point, provided that in the planting itself the soil is packed solidly to the roots. Some discretion is, of course, necessary in this matter, as packing a strong soil too firmly when it is on the wet side may easily carry one too far in a direction which, under considered judgment, is invariably desirable and beneficial. It is superfluous to add that the dibber should never enter into the Strawberry planter's simple tool equipment—all work should be done with a handfork or a trowel, the former for preference, and there ought to be a small ball with the roots if it is within the bounds of possibility. If the site is dry when the task must be accomplished, a state of affairs which one ventures to think improbable this year, the individual positions for the plants should be very thoroughly soaked a few hours in advance, as this is conducive to vastly better results than planting first and watering afterwards.

Distances both in and between the lines vary considerably in accordance with the opinions of different growers and with their knowledge of the growth of particular varieties in their own circumstances. Many gardeners favour 18ins. in all directions to prevail through the three yearly cycle, but while this is too much for the first season, it is commonly insufficient for the second and third years with modern varieties on the majority of soils. Another favoured spacing is 15ins. in all directions for the first year, each alternate row and each alternate plant in the remaining rows being cut out for the second and third years. Then there comes the system under which the rows are set at 30ins. asunder and the plants at 15in. in them, but in this case autumn Onions should always be planted between the rows for the first year with a view to ensuring that full value is derived from the ground utilised; when the Strawberries have cropped once, each alternate plant in the rows must be struck out.

A final word. Spare no efforts which will go to finishing all planting by or before the end of August. The soil is then about at its warmest, and with the pleasant moisture provided naturally or artificially the roots will be encouraged to secure a quick and excellent start, a condition of affairs that goes far to favour a big return in fruit in the first season and, of course, in the subsequent years also.

W. H. LODGE.

STRAWBERRIES IN THE GARDEN

This is the time to lay down the foundation for the Strawberry crop of next season. Time always flies fast, and that which passes can never be overtaken. Decide, therefore, what ought to be done and do it at once with all your might.

BEFORE the whole of the Strawberries of one season have been harvested the grower must commence preparations for the crop of the following year. There must be thought of those plants which have yielded three, two and one burdens, and still other thought for the youngsters which have to be planted to give their first welcome returns in the ensuing summer. While it is certainly possible to plant until the end of September, and even somewhat later in a specially favourable season, and still secure a return in the next year, there is no gainsaying the fact that cultivators who aspire to the production of a really heavy bulk of excellent quality must see that the work is accomplished by the end of August. Again, the quarters which are entering upon their second and third years of bearing may be dealt with much later than this, but the burdens will be considerably prejudiced the longer the necessary tasks are delayed after the present moment.

EXHAUSTED BEDS.

Save in exceptional circumstances plants which have borne three crops may be regarded as having reached the end of their useful lives, and should therefore be grubbed to provide space for something that will give a comparatively more profitable return. Nevertheless, it is wise always to bear in mind that in strong land that was thoroughly prepared and has been intelligently cared for subsequently, and in which the plants have had the attention in summer, autumn and spring which they demand, a fourth crop can be secured. It is not suggested that it will be equal to one, two or three year old beds, particularly in respect of fruits of conspicuous individual merit, but the bulk will be heavy and admirably suited for preservation in bottles or as jam because of evenness of size and firmness of flesh. However, the safe general rule is to uproot all plants which have cropped thrice.

It may be mentioned in passing that after the site has been efficiently hoed to ensure the total removal of weeds it becomes ideal for Broccoli to stand through to the spring, as there is enough food and so solid a root run that the vegetables are not encouraged to that grossness which leads to so many losses during bad weather in the first and second months of the year.

FRUITING BEDS.

Although it is more than probable that one year old plants give the finest individual fruits, those two years and three years old should be, and will be under careful treatment, capable of developing heavy weights with excellent individual specimens. It is necessary that the residue of all mulching material shall be instantly removed as the initial step in cleansing. This done, clear off every leaf that shows the slightest indication of rustiness or is hardening to that state of crinkliness which may be accepted as indicative of small power to assist future progress; at the same time every runner that is not earmarked for a definite purpose will go too. This done there must be perfect weeding as well in as between the lines, and, finally, forking over to encourage the free admission or invigorating fresh air to the soil. When the trimming up is carried to the last degree, as ought to be the rule, the general appearance of the beds will be on the bare side for a brief interval, but the plants will be enabled to build up those splendid crowns which we confidently regard as promising fine crops in future.

As regards plants which have fruited once only, if the planting distance was 15ins. all ways, each alternate row and each alternate plant in the remaining rows should be struck out in soils that are notably adapted to Strawberry culture; while if the original space was 30ins. by 15ins., each alternate plant in the row must be grubbed. The result will be 30ins. in all directions for the second and third seasons of profit, and it is not too much under the best of management. In nearly all instances where the soil is on the strong side an October dressing of basic slag at the rate of from 1ozs. to 6ozs. to the square yard will prove markedly beneficial.

NEW BEDS.

It is in the preparation and planting of these that by far the most important work of August lies, because one is not then taking full advantage of a previously laid admirable foundation, but putting down the foundation itself in such a manner that it will prove efficient for a period of not less than three years. This, it will be generally agreed, is a comparatively brief life, and proceeding on that assumption growers in private gardens have not hesitated for an instant in deciding

THE UNHEATED GREENHOUSE ON A WARMER SEABOARD

A correspondent experiences a difficulty which is probably shared by other readers, and that is to ensure, with only an unheated greenhouse in a locality favoured, as far as temperature is concerned, a supply of plants and flowers during autumn and winter.

UNDER such conditions it should be possible to grow a number of interesting and decorative plants which would be impossible elsewhere. It will be a comparatively easy matter to maintain a suitable temperature; the principal cultural difficulty will be in regard to atmospheric moisture, which is generally excessive on the western seaboard and consequently detrimental to plants in flower. The simplest method of dispelling excessive atmospheric moisture is by affording gentle artificial heat and at the same time opening the ventilators as widely as circumstances permit. With the unheated glass-house this is impossible, so careful attention must be paid to prevention, and, with this end in view, the gardener will, naturally, exercise the greatest care when applying water. Throughout the autumn and winter, when flowers are most required, plants may often be safely left unwatered for considerable periods, and advantage can be taken of sunny days then to afford water, so that a fairly dry atmosphere will be ensured by nightfall. If the floor is paved or tiled it should be mopped up, and as much ventilation as possible should be given at the time of watering. It should scarcely be necessary to say that during the autumn and winter watering should be done in the mornings.

In such a greenhouse as that under consideration there should be no climbers trained to the roof, as these have a tendency to induce a moist atmosphere by restricting the free circulation of air. The flowering plants, in particular, should be allowed ample space—overcrowding always leads to damping and decay of the foliage and flowers, as well as militating generally against their well-being.

For our correspondent's purpose flowering plants will, naturally, be the more important and be grown in the greatest proportion. Chrysanthemums, which, we learn, are already grown most satisfactorily, are very important, and their season can be extended by growing a goodly number of such late-flowering decorative varieties as A. J. Balfour, Bertha Lachaux, Bronze Cheer, December Bronze, Docteur Enguehard, Framfield Pink, Heston White, Mlle. L. Charvet, The Favourite, Tuxedo, White Queen of the Exe and Winter Cheer. In an average season these may be safely left outside until the larger-flowered November sorts have finished flowering.

In the greenhouse of mixed plants it is rarely wise to attempt the cultivation of the Perpetual-flowering Carnation, as, under such conditions, they are not often wholly satisfactory, but if a few are greatly desired the following sorts may be grown: White Enchantress, Lady Northcliffe, May Day, Aviator, Beacon and Triumph.

By potting them as early in the autumn as possible quite a number of spring bulbs may be had in flower towards the end of the winter, but early potting is very essential. Other bulbous and allied plants which will be of value include the brilliant *Vallota purpurea*, which is often so beautiful in cottage windows in the West Country and *Imantophyllum*, better known in gardens as *Clivia*, and of these it will be found that *C. miniata* will flower first and be followed by the greatly improved varieties. *Lachenalia Nelsonii* is useful, especially in that the flowers last a

considerable time. *Primula kewensis* is quite easy to manage and will produce plenty of yellow flowers throughout the winter.

There are several *Begonias* which, if grown out of doors in a sheltered half-shady place during the summer and brought into the greenhouse in the autumn, will continue to bloom for a very long time. The best sorts are *B. fuchsioides* and the *B. semperflorens* varieties. The improved strains of *Streptocarpus* are almost perpetual flowering, so seeds of these sown in the spring will provide plants that would flower well in the autumn and onwards. *Bouvardias* are also valuable for winter cut-flowers, and with an unheated greenhouse it would be best to grow them in pots during the summer, rather than to plant them out and lift them in the autumn. The pot plants can well be plunged to their rims in an ash-bed during the summer to keep the roots cool and moist. *Coleus thyrsoideus* will commence to open its beautiful blue flowers towards the end of January, and the plants may be grown similarly to the *Bouvardias*.

Well-budded *Azaleas*, both of the *indica* and the *Mollis* sections, may be had in flower towards the end of the winter, and although *Camellias* are quite hardy in the West, they are also useful for the unheated greenhouse, while the fragrant *Daphne indica* should also be included.

Generally, annuals would not flower early enough for our correspondent's purpose, with the exception perhaps of *Mignonette* and *Acroclium roseum*, which, if seeds are sown in August, will flower early. If labour and space permit, a deal may be done by growing the earliest hardy shrubs, such as the *Prunuses*, *Pyruses*, *Forsythias*, *Magnolias* and *Viburnums*, in pots. If such are well rooted and placed in the greenhouse early in the winter they will flower considerably in advance of their normal season.

SOME EXCELLENT ANNUALS

(Continued from page 386.)

OF the Love-in-a-Mists, *Nigella Miss Jekyll* seems still to stand alone, but she has a very dwarf colleague, called "double dwarf," which is really excellent for the front of the border or for edgings. Rich dark blue with just a hint of purple, each flower almost like a miniature *Clematis*. *Nigella hispanica atropurpurea* can hardly be called a Love-in-a-Mist, for the flowers are quite devoid of the characteristic "misty" greenery. *Gilia capitata*, like a large-growing *Sheep's Bit Scabious* (*Jasione*) next claims attention; then the curious *Androsace*-like *Leptosiphons*, *aureus* and *androsaceus*. Many varieties of the showy annual *Toad-flax*, *Linaria maroccana*, are under trial. Easily the most attractive is the brilliant "crimson and gold," but the deep carmine rose variety called "pink" also is very attractive.

Yonder patch of brilliant colour can only be the *Crimson Flax*, *Linum rubrum grandiflorum*, one of the really indispensable annuals. Near-by is the brilliant golden *Bartonia aurea*, while those masses of cloudy mauve represent *Asperula*

azurea setosa. Here is *Centranthus macrospilot*, more compact than the perennial *Valeriana*, and beyond rows of rosy-pink and white *Hawkweeds* (*Hieracium*). Those cousins of the *Groundsel*, the annual *Senecios*, are but just coming into flower, but they are cheerful little plants, even though their range of colour does run in bluish tones of pink and red.

Of many sorts of *Coreopsis* under trial, *Drummondii* and *coronata* are the most brilliant, and these, like the more or less perennial *C. grandiflora*, are excellent for cut-flower.

Here are the *Cornflowers* in pink and white and glorious blue, and beyond them the pigmy forms, called respectively *Victoria Blue* and *Victoria Rose*, the latter quite showy and attractive. That species yonder with more spreading habit and larger flowers of a deeper blue than the *Cornflower* we all know and love, is *Centaurea depressa*, the "King of Bluebottles." As we pass quickly on we notice the quick to flower *Acroclium*s, very pleasing "everlastings"; *Kaulfussia amelloides*, excellent edging plants, in blue and crimson; and that quaint and tiny prostrate *Sunflower*, *Sanvitalia procumbens*.

The large patch of *Sweet Sultans* in their several colours are waiting sulkily for finer weather, but the bright-eyed annual *Chrysanthemums* stand soldier-like in rain or shine. Of these the most noteworthy seem to be *Coronaria Coronet*, with a distinct white zone, and *Coronaria double yellow*, which always makes one wonder as to the value of the slow-to-flower *African Marigolds*. Very excellent are the mixed strains of these annual *Chrysanthemums*. A glorious patch of yellow near-by denotes the proximity of the beautiful *Corn Marigold*, *Chrysanthemum segetum grandiflorum*. It would be easy to write columns on other specialities under trial, but these notes are already overlong; so we will pass over the *Ornamental Grasses*, the "Japanese flower-garden" mixture and the mixed seeds generally. We will neither stay to enthuse over the brilliant blue annual *Anchusa*, nor the blue and pink *Clarys*. We cannot, however, refrain from remarking what an excellent foliage plant is the *Giant Hemp*, *Cannabis indica*; and a line must be spared to point out the decorative possibilities of the *Red Mountain Spinach*, *Atriplex hortensis rubra*. With two dwarf annuals, the well named *Oxalis Cloth of Gold*, and the minute *Ionopsidium acaule*, we must conclude these notes, merely remarking that the very complete *Antirrhinum* trials elsewhere in the grounds are alone well worth some little expense and trouble to see.

The Reading trials are carried out on shallow, very light, hungry soil, full of stones and over a subsoil of clean gravel. That annuals can be grown so well upon it should be a great encouragement to those would-be growers who are troubled with shallow, hungry soils.

A Chinese Hemlock *Tsuga yunnanense*.—It has been known for some years that a *Hemlock Spruce* or *Fir* grew in Central and Western China, collectors having sent home dried specimens. More recently Mr. E. H. Wilson, collecting on behalf of Messrs. James Veitch of Chelsea, has succeeded in introducing it into our gardens. Previous to the advent of this plant only three species of the *Hemlock Spruce*, natives of the Old World, were grown in this country, namely, *T. Brunoniana*, from the Himalayas, which can only be grown outside in the milder parts of the British Isles, and the two Japanese species, *T. diversifolia* and *T. Sieboldii*. Compared with the two last-named species, the leaves of the Chinese plant are much brighter green, also larger and not nearly so closely arranged on the twigs as in *T. diversifolia*. Another marked difference is that both of

the Japanese species have blunt-pointed leaves, which are silvery white beneath, while in the young plants of *T. yunnanense* they are green beneath and taper to a point. Whether these characteristics will disappear with age remains to be seen; certainly in a young state the plants are very distinct. The Tsugas are useful subjects for lawn specimens of moderate size. The Old World species are not so tall in growth as their counterparts in the New World, of which the best-known tree is the North American species, *T. canadensis*. Some authorities include the Tsugas as a section of the genus *Abies*.

A Useful Clematis.—That showy, late-flowering *Clematis*, *C. joumiana*, is of particularly vigorous habit, and is well worth growing in gardens where autumn-flowering plants are encouraged. Its origin appears to be something of a mystery, though it is probably a hybrid. Some of its characters suggest that *C. Davidiana* is one parent, while *C. paniculata* or a form of *C. Vitalba* may be the other. It has been distributed as a variety of the Himalayan *C. grata*, but is distinct from that species. Forming strong, sturdy branches, it attains a height of at least 12 ft., bearing large, deep green, five-parted leaves, which are somewhat like those of *C. Davidiana* in shape. The flowers are borne in clusters from the leaf-axils and points of the shoots, the upper half of each branch thus forming a large inflorescence. Somewhat similar in shape to the blossoms of *C. Davidiana*, but not tubular, the flowers in this case are white in colour, stained with violet on the outer sides of the segments. The flowering ends of the branches die back each year; therefore a certain amount of pruning is necessary in February in order that the centres of the plants may be kept free from dead wood. It thrives against a group of rough posts, a trellis, or over an old bush, and is of decorative appearance in either case. Like other species, it succeeds in loamy soil, and is benefited by a fair amount of lime.

A Fine Catalogue of Gardening Books.—

It is pretty generally known among book collectors, librarians and literary workers in horticulture that the Massachusetts Horticultural Society possesses what may be fairly described as the finest library of its kind in the world. Altogether it contains about 22,000 volumes, and in addition there is a unique collection of about 11,000 nurserymen's and seedsmen's catalogues, going back to a period of 150 years or thereabouts. Nearly fifty years have elapsed since the last catalogue of the Society's library was published, and there has now recently been completed a new issue which is a volume of the greatest bibliographical importance from the horticultural standpoint. Part I of this invaluable work was issued a few years ago, but the catalogue in its entirety has only recently been completed. It forms a well printed, nicely arranged large quarto volume in dark green cloth. There are 587 pages in double columns, the authors' names being printed in heavy type. Part I is devoted to an alphabetical list of authors and titles, the arrangement being very full, for we get, first, author's name, followed by the title of his work; then size, number of pages, if illustrated, place of publication and date, with such other additions as may be needful in various cases. The contents of this part may be summarised as follows: Preface, Explanation of Abbreviations and Signs, Authors' Catalogue, Additions, Further Additions. Part II is the Subject Catalogue, the contents of which are, briefly, Table of Subjects, Subject Catalogue, Corrections, Index. There can be no doubt that everybody who has an interest in horticultural literature has, in this remarkable catalogue of a very comprehensive and valuable library, a work

of reference the like of which does not exist anywhere in the world. The information it contains is invaluable, and every book collector, journalist and literary worker in horticulture will find it an immense help if he can place it upon his bookshelf with his other reference books. The price is stated to be \$10, and the work can only be obtained from the Librarian, Massachusetts Horticultural Society, 300, Massachusetts Avenue, Boston, Mass., U.S.A.

ANSWERS TO CORRESPONDENTS

FLOWER GARDEN.

HOLLYHOCKS DISEASED (L. M. S., Chester).—The cause of the trouble is one of the rust fungi. It is not likely seriously to injure the plants. Hand-pick the lowermost leaves and burn them. As soon as flowering begins to go off pull the plants up and burn them.

ANTIRRHINUMS ATTACKED (G. B. B., Twickenham).—The Antirrhinums are attacked by a species of Botrytis which has destroyed the stems just below the flower-spikes. The plants were in all probability weak through some cause, or possibly dead corollas had remained on the plant, and in the damp weather they had been attacked by the fungus, which had, as often happens, spread thence to the living tissues. This fungus forming resting bodies on the dead tissues, and all such diseased material should therefore be burnt. It is difficult to suggest any really effective measures for the control of such a fungus, but probably the best is to give ample space in order to allow air free play among the plants.

REPLANTING DELPHINIUMS AND LUPINS (C. B. W.).—The best time to transplant Delphiniums and Lupins is during September and October. In order to get as fine spikes as possible special attention should be paid to the border, particularly for the Delphiniums, which delight in a rich, well worked soil. Slugs often attack Delphiniums during winter and early spring, so their depredations should be guarded against.

SWEET PEAS UNSATISFACTORY AND OTHER QUESTIONS (E. F. P., Penrith).—The Peas are probably adversely affected by the presence of water too near the surface. If means can be devised for getting rid of the surplus water and a dressing of lime can be given, we think Peas should succeed with our correspondent. In addition to Primulas of many kinds, our correspondent might grow *Trollius* sp., Ferns of many species, some *Spiraea*, *Phloxes* (if not too shady), Irises, such as *Sibirica*, *orientalis* and *elysiographes*, *Saxifraga peltata* and *Lysimachias*. Dusting sand moistened with paraffin along the rows is the best preventive against carrot fly.

BULBS DISEASED (W. S., B. S.).—The diseased bulbs should be carefully picked out from the bulk and burned and the healthy ones should be steeped in a solution of formalin, 1 part to 200 parts of water, for two hours and dried before planting.

THE GREENHOUSE.

TOMATOES ATTACKED (H. J. R., Cornwall).—The Tomatoes are attacked by black spot. All the diseased fruits should be removed and buried, and care should be taken that the watering is quite regularly done so as to avoid the danger of causing the cracking of the skin of the fruit. This is to be done to a considerable extent by watering at weekly intervals with sulphate of potash, ½ oz. to 1 gallon of water.

FRUIT GARDEN.

FIG TREE ATTACKED ("Fir").—There are two fungi on the Fig shoots, the one forming red pustules called *Nectria cinnabarina*, the other with grey patches, *Botrytis cinerea*. Both have gained entrance into the shoots through wounds, and avoidance of wounding is the most important measure to adopt. Probably also the soil for the flower border has been manured, and the trouble has doubtless been aggravated by this treatment.

FRUIT UNDER GLASS.

GRAPES UNSATISFACTORY (Miss L., Somerset).—The Grapes (Black Hamburgh), as well as having been attacked by mildew, show evidences, in the form of "pitting" and shallow sunken areas, of unhealthy conditions. Our experience is that where the range of temperature has been too wide and where the heat has not been properly controlled Vines become weakened and readily susceptible to disease. Syringing with too cold water and ineffective ventilation also predispose to disease. Our correspondent would be well advised to pay close attention to cultural details as a general safeguard. The rods, after pruning, should be thoroughly drenched with a solution made by dissolving 1 lb. of copper sulphate in 25 gallons of water. This should be applied towards the end of November.

KITCHEN GARDEN.

POTATOES UNSATISFACTORY (M. B.).—Our correspondent does not give us any particulars as to source of seed, varieties doing badly, previous cropping, or cultural treatment and manuring, all points which would assist us in our examination. The specimen sent shows general dwarfing, due, possibly, to insufficient feeding; evidences of root-feeding insects which may have caused a "girdling" or "ringing" effect, which is quite enough to produce stunting; evidences of leaf scorch, due, possibly, to lack of potash manures; that the tubers were suffering from the effects of a slight cessation of growth, being followed by a stimulation to rapid growth, an effect due possibly to drought conditions followed by rain. This has caused growth cracks to appear, and rot has apparently followed.

CABBAGE QUERY (C. B. W.).—The purplish colour on the outer leaves of seedling Cabbages is caused by their having received some check to their growth, but if the plants receive ordinary treatment afterwards it is not detrimental to them.

PARSNIPS ATTACKED (L. M. S., Chester).—The Parsnips, though containing no larvae on arrival, have apparently been attacked by the carrot fly (*Psila rosea*). This fly deposits its eggs beside the developing tap-root. These eggs produce the small larvae which gnaw at and tunnel into the roots, often causing considerable loss. It is probable that the fly is attracted to the young Parsnips by the smell of the bruised plants or broken rootlets at thinning time. One very successful grower known to us states that he gets practically no trouble from this fly when he sows his seed very sparingly and does not thin out. This method would be well worth a trial. If our correspondent must thin, however, sprinkle sand soaked in paraffin along the rows after thinning to disguise the smell of the bruised plants. As an alternative powdered lime and carbolic might be tried. Nothing can be done this year, but the ground should be cultivated deeply and thoroughly before next year's sowing.

MISCELLANEOUS.

DESTRUCTION OF WEEDS ON POND (C. L. H., Totting).—Calculate the number of cubic feet in the pond and multiply the result by 6½. This will give approximately the number of gallons of water in the pond. For every 10,000 gallons of water put into a loose canvas bag 2½ ozs. of copper sulphate, and draw the bag across and athwart the pond through the water until all the copper sulphate is dissolved. This will kill the weed without injury to Lilies or fish.

No. 2648.—Vol. LXXXVI.]

[AUGUST 19, 1921.]

EVERGREENS FOR VARIOUS SOILS AND SITES

THE planting season for evergreens will shortly be upon us, indeed where very large specimens have to be moved, possibly without previous preparation, it would be well to put the work in hand at once. Ground for permanent planting of any kind can hardly have too thorough a preparation, but such preparation will vary considerably with the soil

which it is proposed to plant. Light moderately fertile loams will need no special preparation other than thorough trenching, burying the turf, if any, face downwards in the bottom, for the generality of Conifers, including that invaluable hedging plant the Yew. In lime tree, the addition of a fair proportion of well-rotted leaf mould and spent hot-bed manure or, failing these, peat will suffice

to make such a soil suitable for Rhododendrons and other American plants. There is no need to incorporate such vegetable matter in more than the top foot or 15 ins. of soil, as such plants are always surface rooting.

Thin soils over limestone or chalk present a problem of their own. It is difficult to keep a sufficiency of vegetable matter in them to satisfy

EVERGREEN AND DECIDUOUS RHODODENDRONS (AZALEAS) IN WOODLAND.

even such unexacting trees as the majority of Conifers. American plants must be ruled out entirely. Even the provision of specially prepared beds, with entirely new soil, is not really satisfactory. The young plants soon begin to sicken and seldom survive for more than a year or so. Of Conifers the undermentioned usually flourish when once established, but it is wise to establish them in specially improved compost containing a fair percentage of decent loam in the first instance.

Common Spruce, Larches both English and Japanese, the Corkscrew Fir (*Pinus Pinsapo*) and those other splendid Firs, *Picea magnifica* and *P. nobilis*, all thrive once established; while *P. Nordmanniana* is spoken of favourably by some planters on chalk, though it is certainly less to be relied upon than the others. Of Pines, the Austrian, Corsican and Scotch all succeed; so do the Bhotan Pine, *P. excelsa*—an excellent substitute for the Weymouth Pine—and the Cluster Pine, *P. Pinaster*. The Maidenhair Tree, *Ginkgo biloba* is chalk-loving. Practically all the race of *Arbor-vitæ* succeed, including that accommodating tree *Cupressus nootkatensis* and most Junipers, including the Savin, the Chinese, the Irish and the Virginian. Cedars have also been satisfactorily established on chalk though some find the Cedar of Lebanon more difficult than the Atlas Cedar or the Decedar. The "blue" variety of the Atlas Cedar seems as satisfactory on chalk as the typical green form. The Wellingtonia, too, once established, is quite successful. It is better as a rule to dispense with the Lawson's Cupresses, which have, during the last few decades, been planted far more lavishly than their merits would warrant. The typical tree, however, has been established on chalk, also the varieties *Trompbe de Boskoop* and *Album*, two of the most useful, and the very distinct erecta variety, *Cupressus macrocarpa*, an excellent hedging plant succeeds on heavy soils, but it must be remembered that this species is hardy inland only in the south and south Midlands. Hollies will not survive in sour soil, yet thin soils over limestone or chalk need some improvement before Hollies will really thrive.

Stiff clay soils are perhaps more difficult than chalky ones to furnish. It is true that there is here no class of evergreen which may not with trouble and by the importation of more suitable soil, be grown, but the working of really stiff soils to make them suitable for Conifers of any kind is a serious business. Leaf mould, drift sand, road scrapings (free from tar), and fibrous loam—even that from the top spit of a stiff pasture is helpful—may all be pressed into service to provide that easy root-run which the fine root hairs of Conifers need. Nor must adequate drainage be overlooked on such soils. I am in favour of common shrubs, excluding Roses or, in fact, any really heavy soil.

Of flowering evergreens, also, there are some which will flourish in a light soil, whether chalky or not. Such evergreens, probably of species, These are especially valuable because they will grow in partial shade, though some deciduous species, such as *Berberis vulgaris* and *B. Humberti*, chiefly valuable for their autumnal colour, should not, of course, be planted otherwise than in full sun. The same may be said of that now large group of species cultivated principally for their ornamental fruits. Such as *B. B. Wilsoni*, *subcordata*, *Prattii*, *polyantha*, *distachya*, *umbellata* and the almost innumerable hybrids of these. None of these, of course, is called evergreen, but like the Brooms they have a wintering effect in winter even when destitute of berries. The Laurel, including the Portugal variety, should not be planted on lime free soils, especially on the coast or in low free soils.

MOST USEFUL OF FLOWERING SHRUBS, *BERBERIS STENOPHYLLA*.

THE GRACEFUL AND ORNAMENTAL *ESCALLONIA PHILIPPIANA*.

PINK AND ROSE EARLY TULIPS

Being an account of a trial at Whitewell.

The Rock Roses (*Cistus*) seem to thrive on any light soil, but perhaps they withstand frost better on one with a fair lime content. The Escallonias are equally accommodating, so are the evergreen Euonymuses. The Escallonias are, of course, not hardy in colder districts and the evergreen Euonymuses are only of practical use where sea breezes can reach them. All evergreen Privets, the Laurustinus (*Viburnum Tinus*), the Rose of Sharon (*Hypericum calycinum*), the Yuccas and Lavender are other shrubs planting nothing better than a fairly light soil.

It is a great thing to know which shrubs and trees are likely to succeed on a particular soil, but it is vital, in addition, to know which of the "possibles" will yield desirable effects in the garden. In some landscapes, heavily timbered with deciduous trees, the use of Conifers at all is to be deplored as giving a spotty effect and so spoiling an otherwise beautiful view. Such sites are few and far between, but the number of gardens which have been planted with *Cupressus Lawsoniana* and its varieties, to the serious detriment of the garden itself and its surroundings, is legion.

Conifers in the average garden can only be a setting. There is not space for them fully to display their beauty as individual specimens and the simpler the setting and the more it is in keeping with the landscape, the more satisfactory will be the result. Of all Conifers the Scotch Pine is most in keeping with the scenery of our less pastoral counties. The reasons for its comparatively small use are probably (1) it does not transplant readily except when young, and (2) it does not grow as rapidly as the much planted Douglas Fir. The value of this latter tree as a screen for shutting out unsightly objects cannot be gainsaid, but it has an exotic appearance even when planted in a grove. Its colouring, too, is overlit to form a satisfactory background to colour so that some more satisfactorily toned evergreen should, wherever possible, be planted in front to provide the necessary background. The Colorado variety has, of course, the necessary colour, but lacks the quick growth which is the principal attribute of the "Douglas."

The Scotch Pine is, on congenial soil, a rapid grower, but is certain in the long run to go bare at the base; so that, near the flower garden, space should be provided in its case also for lower planting to provide a solid background. Less exotic looking than the Douglas Fir, the Austrian Pine "furnishes" better than the Scotch Pine, but is rather funereal in appearance. It also must be moved when small and even then is somewhat liable to be uprooted by strong winds. The Weymouth Pine, *Pinus Strobus* and the Bhotan Pine, *P. excelsa*, are too sparse in habit and too pale in colouring to make satisfactory backgrounds.

The Cedar is a fine tree, too valuable and too distinctive, of course, to use for backgrounds, but admirable, despite its rather un-English effect, for avenues and as a specimen tree. Despite its most attractive appearance when young the Deodar as a grown specimen is noticeably inferior to both the Atlas and Lebanon Cedars. How many fine Cedars there are to be seen, their branches almost touching the windows of what should be living-rooms, but which are in fact little better than family vaults for comfort! The owner has had to choose between the tree and comfort indoors and has (from a tree-lover's viewpoint, not unnaturally) chosen the tree. Cedars of all sorts should be kept quite away from the house and in positions where room can be afforded them to develop fully. This means that space cannot be found for them in any garden less than two or three acres in extent.

The Spruce is a beautiful tree which, if allowed, will retain its foliage to the ground. It should be planted in groups rather than as individual specimens.

ALTHOUGH Darwin and Cottage varieties claim the pride of place nowadays in our gardens, it was not always so. We were once glad enough to have the "earlies" to give us, along with the Hyacinths, the first reds and pinks of the year. It was a welcome change from all white, yellow, purple and blue. They still fulfil the same purpose and we are loath to banish them altogether. There is nothing to take their place at the early period of the year when they are in bloom. Not that I would limit my choice altogether to pinks and reds. The very shape of their flowers provides a different

look, for the Crocuses are past and over before it is their turn on the stage. Then sentiment comes in and pleads with all the force of a Sir Charles Russell for their retention. A garden cicerone ought to have a tongue. Is it nothing to take visitors to see, say, a patch of *Couleur Cardinal*, and, finding that two or three have cast aside their demure coats of deep crimson and plum and appear in far gayer dark red and rich yellow stripes, to point out how any self coloured flower may another year become a striped one? Is it nothing to be able to say of any of these striped earlies, "It was such flowers as these that created the mania," and then to go on and tell a few tales of that most exciting and extraordinary time? I think it is almost certain that *Semper Augustus*, *Admiral van der Eyck* and the rest were Tulips of the early type, whose counterpart we get now in *Admiral Reimier* (red and white stripes), *Golden Bride of Haarlem* (scarlet and yellow), and *Fabiola* (rosy mauve and white stripes). This is why the earlies always appeal to me. Any broken or rectified "early" is, in its way, a modern

replica of those famous flowers. One astounding fact about the mania time, and which shows how artificial it all was, is the fact that bulbs in the end came to be sold by weight! Fancy Sutton's opening an order for two pennyweights of *Cottage Maid*, or *Barr's* for an ounce of *Prince of Austria*, as if they were peppermint humbugs or boiled fruit drops! No, I would not like to be without some earlies, although visitors to my garden find them few in number compared with the more important and more popular long-stemmed Darwin and Cottage varieties. I take them up in relays. In 1920-21 it was yellows, and readers may remember how high in my list I placed *Prince de Ligny*. I want to add to it *Rising Sun*, *Jaune Supreme* and *Hildebrand* of the lesser known ones in the order named. These make a grand quartet. Last time, in 1921-22, I went in for the pink and rose

shades. My collection of thirty-six varieties is not a complete one, but it included pretty well all the best known ones like *Cottage Maid*, *La Reine* (this is not pure white outside), and *Jenny*. These were quite sufficient in the long bed to pick from. Before going into details I would ask readers to remember that what follows applies entirely to their behaviour out of doors and that this last spring has been a very rotten one for these early birds. *La Reine* has already been mentioned. It is grown by the ten thousand for forcing for market and then it is a pure white. Outside, however, it develops a pretty pink edge. It is rather a poor

TULIP PINK BEAUTY.

little flower in itself, but it has a peculiar facility for sporting, and unless my eyes have deceived me it has given rise to a good many novelties. There is a pinky set and a rosy set. I may say at once I am not very keen on any of them. Somehow they have too unkempt an appearance to please me. Perhaps I am too fastidious about shape for I have a seedling Tulip which we call *Rosy Morn* which, in a mass, is the most glorious bit of colour that anyone can wish to set eyes on, but alas! many flowers come rough and produce more petals than they ought to do. I am inclined to scrap it. "No," says my head man, "you must not do any such thing. Let us grow it on. Such a lot of visitors say they like it just because it has not such a strait-laced look like most others and is a bit unconventional. For garden decoration it does not matter a pin." So *Rosy Morn's* life is spared and next year there

will be a goodly stock, and it ought to be a great sight. I hope I am not doing the sports of La Reine an injustice in saying none of them appeals to me, but I am now recording my personal likes. Of one thing I do feel confident in writing about them. They are not all wanted. They are too near to one another for their differences to be really appreciable in a garden. Prosperity, Flamingo, Ibis, Rose La Reine and Ariadne (rosy spots) are not all wanted. Ibis is my choice. It is very bright looking and has a more decided colour than the others. Rose Falcon, Princess Juliana and Blushing Bride are a pinky trio. The most taking is the last named.

This gets rid of a fair proportion of the trial. Of the others I plump for the following: Van der Helst (Princess Wilhelmina is almost identical as I have them), Rose Tendre, Alice Roosevelt, Rose Aplatie, Roos van Dekama, and Pink Beauty. Jenny and Proserpine were included with the others. Both are excellent for bedding. They are roses, it is true, but only just. Carmine-rose they are often labelled. But then Pink Beauty is no more pink than a scarlet hunting coat. But as Shakespeare (or, as a learned and determined Exmouth friend would have had me write, Bacon), says, "What's in a name?" If Pink Beauty is a deep rose—in some lights almost red—it is a grand garden Tulip—a veritable "Bobby Spencer" among its fellow members of the House of Pink and Rose. There's no agricultural labourer's look about its smart, dapper appearance. It no more looks like one than my Rosy Morn looks like a florist's breeder of the first water. Seeing Pink Beauty in a garden for the first time, you are bound to ask, "What's that?" Rose Tendre I have long known as an improved Cottage Maid for pots. I also place it above that well known and popular variety for outside, Rose Grisdelin. Alice Roosevelt was new to me. It is a particularly delightful shade of real pink, large enough to please anybody and a good laster. In early life it is very nearly a self. If these lines are read by any of my Dutch friends, I would very much like to know if Van der Helst and Princess Wilhelmina are considered to be synonyms; if they are different, there's very little in it, so little that it does not much matter which one has. I feel sure, unless the wrong bulbs were sent to me last year, that the R.H.S. book errs in placing them in different colour sections. Much the largest patch was labelled Van der Helst. It is a pointed flower, deep rose, with a pale flame on the exterior of the petals, and of quite a respectable height. It was in full bloom in early May, at least ten days before Pink Beauty. Rose Aplatie is very much on the dwarf side, but it is a taking, square-shaped flower and attracted me because the pink was so much paler than in all the others from the start to the finish. Roos van Dekama—my last "Spot"—does not seem to have been in the R.H.S. trials in 1914-15, but I have long known it as an A 1 plant for pots. It is very nice outside, too. It, like Rose Aplatie, is rather a dwarf, but its wide, deep rose and pink petals give it an air of distinction and importance. I think a mixture of Roos van Dekama and Rose Tendre in a bed would be most effective, as the difference in their heights would take away that stiff look which cannot be avoided if one variety only is used. I think I ought to mention Rose Duc van Thol. It was almost over when I arrived home and saw it for the first time, but my landlady told me the pretty little pink flower had stood all the rough weather without turning a hair.

By the way, can anyone tell me anything about a wonderfully charming and distinct small double which was sent to me for trial by my friend Mr. Bull of Ramsgate? He describes it as a coral pink, and he sent it under the name of Rose La Reine. It is such a pleasing little flower. JOSIE JAYOU.

THE REGELIO-CYCLUS IRISES

SOME little time ago (June 24, page 307), you published a photograph showing one of the beds of the Regelio-cyclus Irises as grown at my Zwanenburg Nurseries. Judging from the poor and disappointing results the Oncocyclus or Cushion Irises mostly give, some people are only

trans-planting every year, gives a wealth of flowers the first season after being planted, coming into bloom at a period when all the tall Bearded varieties are only just showing buds.

It may be that their success here is partly due to our porous, sandy soil, full of lime, but on the other hand cold, wet, heavy soils are just as unsuitable to the ordinary Bearded Irises and anyone who has a warm, sheltered garden in good cultivation, so that he can grow the Bearded Irises well, can safely try the Regelio-cyclus varieties. Visitors to the Chelsea Show had the opportunity of seeing great quantities of these flowers, English grown, and cut from the open ground only the day before the opening of the Show, which proves that they do not want the "favourable" climate of Holland to develop well.

Readers of THE GARDEN who are not yet acquainted with the origin of this class and wonder why the Regelio-cyclus class always does well, as compared with the capricious Oncocyclus group, must not overlook that they have been saved from varieties of the various Regelia Irises (Korolkowi, Leichtlini, vaga), crossed with the best forms of the Cushion Iris (iberica, Lortetii, Susima). The former never give any disappointment, forming in one season big clumps with many flower stems. The progeny of these crosses, to wit, the Regelio-cyclus group, have inherited the free-flowering qualities of the seed parents, as well as the

REGELIO-CYCLUS IRIS POLYHYMINIA.

too ready to think that the Regelio-cyclus behave in the same way. Much already has been said in the columns of THE GARDEN by enthusiastic amateurs, who reported their experience with these Irises, stating that they were quite satisfactory and flowered well for years in succession and I once more venture to bring this topic to the front. Our Dutch climate is by no means so mild and sunny as is sometimes believed; we had a truly arctic, inclement winter, the ground in our garden was frozen more than 1½ ft. deep and our summers are mostly cool, with more cloudy days than bright sunshine. Notwithstanding these facts the Regelio-cyclus Irises, which I have now grown for more than a quarter of a century, always do well and flower very profusely, as the photograph clearly showed. It is no exaggeration to state that they flower more freely than the common Bearded Iris, which certainly give a mass of bloom, but only if they have been left untouched for some years; transplanted rhizomes generally want a year or more to get established. The Regelio-cyclus group, which requires

noble shape of flower which distinguishes all the pollen parents.

Culture may be briefly summed up as follows: select a warm, sheltered spot in the garden, for preference at the foot of a south wall, and work it deeply to ensure perfect drainage. If the soil is poor, mix a fair quantity of old pulverised cow dung in it; if the ground be heavy, use plenty of sharp silver sand and surround the rhizomes with it. This will facilitate the formation of roots. Soils that are destitute of lime must be mixed with finely crushed old mortar. Plant about the middle or end of October and cover the rhizomes to a depth of about 3 ins. in heavy soils, rim more in light soils. Carefully spread out the fleshy roots attached to the rhizomes without huddling them together.

Where the soil is on the heavy side, plant, if possible, on a slightly raised bed, which will allow all superfluous water to drain away easily in winter. As these Irises are hardy, they require little protection in winter, but to prevent the soil getting beaten down by continuous heavy rains, a covering of dry boughs will suffice to keep

the soil soft and manageable. About the middle of July, as soon as the foliage shews signs of turning yellow, lift the rhizomes, leave them in the open air for about three or four days to ripen off thoroughly, cut the foliage to about 4 ins. from the crowns and shorten the roots a little. The rhizomes are then stored away in an absolutely dry, rather warm place (a shelf in a vinery is a capital spot), until planting time comes round again. If necessary the clumps may be divided then.

The variety *Polyhymnia*, of which I send a picture, is one of the best of my recent seedlings; it is the result of a cross between a specially large

flowering strain of *Regelia*s, found by my collector some years before the war in Bokhara, and some of the best *Oncocyclus* forms. These flowers are much superior to the original Korolkowi varieties as introduced by the Russian botanist, Dr. Regel of St. Petersburg, and crosses between this strain and the *Oncocyclus* have given remarkable results. The variety *Polyhymnia* has stately stems, 20 ins. tall or more, and bears uncommonly large flowers of noble *Oncocyclus* shape, with well rounded petals of a delicate creamy white, netted and veined all over with pinkish brown.

Holland. C. G. VAN TUBERGEN, JUN.

THE TALLER COTONEASTERS

ALTHOUGH not commonly seen in gardens, *Cotoneaster pannosa* can claim to be one of the best of its race. Hailing from Yunnan, the home of so many good things, it is perfectly hardy and of the easiest culture almost anywhere. *C. pannosa* merits a foremost place among its clan because it is not only a free and handsome berry producer, but because of the graceful habit of its evergreen branches, which are most elegantly tapered and arched. The wine-red stems prove an admirable setting for the downy, grey-green leaves, which in their turn make a fine background for the bright crimson berries. These fruits, pear-shaped and in small pendent clusters, are yielded so generously that it is not an uncommon experience to see every twig on a large bush terminated with its prettily poised bunch. Moreover, since birds do not seem fond of them, the fruits often remain on the branches until early spring. *C. pannosa* grows 7 ft. to 8 ft. high and makes a good specimen bush.

C. Franchetii is not unlike *pannosa* in stature and general appearance. The evergreen foliage and young wood are rather more downy and, if the bush is not so graceful, it excels during the flowering period, for the blossoms are rather larger than those of the above-mentioned and they are effectively splashed with bright pink on the outside. On close inspection they resemble tiny wild Roses. The fruit which ripens early (September), hangs well and is a pale orange.

Another species, introduced about twelve years ago, which has rosy flowers and is a handsome bush when in fruit is *C. Zabelii*. So far, this one has not attained a height of more than about 4 ft. with us, the several fish-bone branches radiating upwards and outwards from the base like the fronds of a Fern, but it will doubtless grow higher. The berries are pear-shaped, bright red, and the rather broad, rounded leaves are a grey-green with white undersides.

In foliage and fruit *C. Dielsiana* runs the last mentioned rather close. But this deciduous species is distinctive in its habit of growth, the branchlets breaking in angular planes from the main stems, as in *C. horizontalis* and others, a feature which has given the species the synonym *applanata*. Berries are copiously produced upon every twig and they ripen to crimson in autumn. Like *C. pannosa*, this species often has a crop of self-sown seedlings coming up about it. It will attain the proportions of a small tree.

The evergreen *C. salicifolia floccosa* is, as its name suggests, a willowy shrub of exceedingly graceful habit, the long and slender whip-like branches sweeping over in a charming way. The pointed narrow foliage is also willow-like and the highly glossed leaves are rendered still more attractive by being bronzed above and white, or nearly so, on their undersides. This *Cotoneaster*, in common with the next mentioned, appears to be

rather longer coming into the flowering state than most. A specimen here is some 5 ft. high, but it has not berried freely yet. The fruit is nearly as large as that of the Mountain Ash, a bold crimson-red and produced in bunches which stand out conspicuously from the sparsely foliated branches.

FRUITING SPRAY OF COTONEASTER FRIGIDA.

C. salicifolia floccosa was brought over by Mr. Wilson from Western Szechuan about ten years ago, being preceded, I believe, by a few years by its near kinsman, *C. rugosa* var. *Henryi*. This would appear at a glance to be merely a much enlarged form of the other, being more robust in habit and bigger in all its parts. It has not yet berried here, but the fruit, I am told, is not yet proportionately larger, but has more orange in its crimson than that of its lesser prototype.

In *C. Simonsii* we have a shrub that is too well known to need description. It is, however, one which is seldom appreciated at its full worth, for a good specimen, a dozen or more feet in height, bearing its large crimson or vermilion fruits when the fall of the richly tinted autumn foliage leaves the branches bare is a cheerful sight at the end of the year.

Not unlike *C. Simonsii* is the evergreen species *C. angustifolia*, now called *Pyraeantha angustifolia*. This is a handsome shrub of 5 ft. to 6 ft. and a good wall subject, in which position it will often go to a much greater height. It makes a brilliant autumn display when laden with its gorgeous clusters of orange-yellow berries. A good town shrub.

Though seldom seen, *C. moupinensis* (*bullata*) is well worthy of wider popularity, for though its branches are somewhat sparsely foliated with "blistered," pointed leaves, 2 in. or more in length and half as much in breadth and the flowers insignificant, the glossy fruit is as large as a small Cherry and a rich blood crimson. These berries are borne in copious flat clusters, but they unfortunately afford an irresistible attraction for birds. *C. moupinensis* makes a large, thin-habited shrub.

Another deciduous species which hardly attains to its dimensions and which is in form more akin to *C. Zabelii*, is *C. houpehensis*. The spreading, gently curved branches of this shrub are thinly furnished with rounded, grey-green leaves above which are produced in early autumn the conspicuous corymbs of white flowers. *C. houpehensis* has not yet set fruit here, but it is, when in blossom, one of the most notable of its race, the flower-clusters being not only large, but of good pure white and disposed along the branches after the manner of *Spirea canescens*.

C. frigida is a deciduous tree some 20 ft. in height with abundant velvety foliage of a tender shade of green. When in full fruit this is a most handsome species, certainly among the best of berry-bearing trees. The fine bunches of large berries are a vivid orange-scarlet, but birds like them and they do not stay long should the early winter be severe. There are several forms of *C. frigida* marked by differing foliage and by variations in the size and colouring of the berries.

Though usually grown as a creeping shrub, and often unnaturally pinioned with nails and wire against a wall, *C. horizontalis* will make a specimen of considerable size if allowed full freedom for expansion and a good soil. For that reason I am induced to include it here. Its excellent attributes—the fine autumnal leaf-colouring and wonderful fruiting propensities, are well enough known, but these are not enjoyed to the full unless the shrub is, as I have suggested, given the opportunity of

disposing its long "mill-sail" branches in a tree and natural manner. A good specimen of *C. horizontalis* will, under such circumstances, cover an area with a diameter of 12ft. to 15ft. Of the variety known as *C. h. purpusilla*, which is said to be somewhat smaller and denser, but otherwise equally desirable, I have had no experience. But the quite prostrate form, originated in Mr. E. C. Buxton's garden, with the fish-bone branches disposed in flat, creeping, horizontal planes, is quite as large in all its parts and as robust as the type, a shrub of rare beauty in habit, leaf and fruit.

The latest addition to the horizontalis family is *C. h. variegata*. This is a distinctly variegated form of the type, the leaves being margined with creamy white, which alone strikes an uncommon note in this genus, but, in addition, the variegated leaves assume wine-red, purple and other autumn tints which are not apparent in the typical plant. *C. h. variegata*, for which we have to thank a French grower, is a valuable addition to the Coto-naster family, but whether it will prove to be quite so free-growing and vigorous as the original there would seem to be some reason to doubt.

N. Wales.

A. T. JOHNSON.

SOME GARDEN GROUPINGS

MANY a keen gardener has no liking for, or cannot be bothered with, elaborate colour schemes in the garden; but few can go through the gardening year without noting with extra pleasure at least a few happy associations of plants with one another. Here are some notes of groupings that have struck me lately, some of them accidental, others designed. I pass them on for the amusement of others who may enjoy the same game.

Early in the year nothing in any garden gave me so much pleasure as a mass of *Crocus Tommasini* thickly interwoven with *Iris reticulata*. In light soil, in a little enclosed spring garden, both bulbs had multiplied amazingly and the play of colour from pale amethyst to the deepest violet purple made a most lovely sight.

Later in the spring I noticed how well the grey-blue flowers of *Rosemary* served as a contrast to the pale yellow of *Cytisus præcox*. There are some other blue flowers, including blue *Columbines* and *Scilla campanulata*, which carry on and intensify the colour of the *Rosemary*.

It is not often that one sees that wonderful shrub, *Berberis Darwinii* used in perfectly appropriate company. A beautiful planting that I saw this year was a tall tree of the *Barberry* leaning up a face of grey rock; leading up to this, on either side of the path, was *Narcissus Lucifer*, backed by half shadowed clumps of the giant *Crown Imperial*. The orange crowns of the *Narcissus* took up the colour of the *Barberry*, and the pale yellow perianths seemed more beautiful in that place than white ones would have been.

Another grouping which I noted at the same time was that of *Helleborus*, with the green-flowered *Correa viridis*. But this is a planting too discreet and colourless to be of interest to most people, and the *Correa* is of course only hardy enough for the mildest localities.

Rosa Hugonis is curiously beautiful in the company of *Solomon's Seal*; *Dielysia spectabilis* and *Iris flavescens* are worth adding to this group. *Escallonia Langleyensis* is splendid trailing over a foreground or a wall planting of the *Red Valerian*. I should like to see this on a big scale. I notice, by the way, that many who know this delightful shrub do not know the paler but no less beautiful

sort *Edinburgh*, or *Donard* seedling. *Edinburgh* is indispensable. Here are some groupings from the herbaceous border—very simple ones, mostly of similar colours. *Eryngium Oliverianum* with *Montbretia G. Davison*; *Monarda didyma* with red *Pentstemon* of the colour of *Newbury Gem*; *Erigeron Quakeress* with or behind dwarf purple *Lavender*; *Lilium croceum* with *Clematis recta flore pleno*; *Ceanothus Gloire de Versailles* with *Aconitum volubile*, *Clematis Perle d'Azur*, and a foreground of *Potentilla Friedrichseni ochroleuca*. This last grouping, which I think I referred to in these columns some years ago, is certainly very beautiful, both in form and colour. *Ochroleuca* is better for the purpose than the ordinary *P. Friedrichseni*, being paler in colour, but either will do. If you can get the *Clematis* to grow up into a tree, say an *Apple tree*, behind or among the *Aconites*, so much the better. The *Aconites* will run up 6ft. high or more and will need very little

staking if the *Ceanothuses* and *Potentillas* support them properly. The *Ceanothuses* should, of course, be cut hard back in the spring, leaving those at the back rather taller bushes than the front ones.

Let me recommend those who do not know *Lilium Pseudotigrinum* to make its acquaintance. In the article on *Lilies* in *THE GARDEN* of August 5, this species was omitted, but it is certainly very easy to grow and of the highest beauty, much more graceful than the common *Tiger Lily*. So far as I have tried it it does not seem to object, as the *Tiger Lily* sooner or later does, to a chalky soil. It is most beautiful in colour with creamy white flowers, such as *Clematis Flammula*, and with grey-green foliage such as that of *Buckthorn*.

In conclusion, have you ever used *Teucrium fruticosum* (on a wall) as a background to *Gladiolus primulinus*? If not, do try it; it makes an incomparable foil, especially to the pure pale yellow sorts such as *Canopus*. A PAINTER.

NATURALISING DAFFODILS

CAN one ever, I wonder, have too many *Daffodils* planted, in as natural a way as possible in little dripts and clumps among plants or shrubs in the mixed border or, space permitting, in wide flung masses amid thinly planted trees, so that a veritable sea of golden glory results and one

far as flowering is concerned; the bulbs live upon their stored-up energy, but the overdraft has to be met and, the following year, if flowers are poor and sparse, one should think backwards to the date of planting.

While it is true that some *Daffodils* will not thrive for a period of years in the cultivated border,

DAFFODILS NATURALISED AT WARLEY PLACE.

almost loses sight of the grass in which they are growing.

At this season the *Daffodil* cycle of growth starts afresh. Pictures like those on this page do not "happen," they are created by the flower lover. Nature is always ready to back our efforts, however, and respond to our attempts; even, in many cases, in time largely to correct our errors, but she exacts a certain amount of effort on our side before she pays the reward.

A golden rule is to plant the bulbs early. This season the work may be put in hand at once since abundant rains have made soft the ground. Late planting may not shew so badly the first year, so

I do not believe that there is a single one that will not do so in grass; it is the natural home and one and all, without exception, do remarkably well in it. Should you be so happily placed that you have a piece of undulating ground, by all means seize upon it—you cannot possibly improve upon this; the small hillock, dipping into a miniature valley, is a possession to prize.

By all means include as many classes as possible, for thus will naturalized *Daffodils* give the greatest possible display of bloom. Glorious trumpets, yellow, white and bicolored, *Incomparabilis* with short cups and yellow or white perianths, *Barrii*, starry *Leedsii* with white perianths and cream or

citron cups, tinged with pink or apricot, Jonquils, Poeticus and double forms, one and all must be pressed into service if the broadest, most perfect and most lasting pictures are to be procured.

Another thing to which too great importance cannot be attached is natural grouping. No formality must appear anywhere. Take the bulbs by handfuls, fling them from you across the ground they are to occupy, plant where they fall and one can make but little mistake.

The following list of excellent, reasonably priced Narcissi for naturalising includes varieties to give at once the longest possible display and the best possible massed effect consistent with such length of flowering.

The earliest varieties to flower of those suitable for naturalising under turf are Golden Spur, Henry Irving and the gigantic, but not yet very low priced, King Alfred. Flowering at about the same time there are the dwarf golden yellow Nanus, beautiful on a grassy bank, and the delightful creamy-white Moschatus of Haworth, which will flourish in cool soil in semi-shade or on a bank with a north aspect. About the same time there flowers the Tenby Daffodil (*obvallaris*), which also does best in partial shade and is quite ideal for naturalising.

A little later than those just mentioned comes Lobularis, an admirable dwarf bicolor, for half shady banks where its beauty can properly be appreciated. Still a little later and the Lent Lily of our own damp meadowlands is in flower. This is quite easy to naturalise in damp grassland or not too shady woodland, though it always proves a failure in the garden proper. At the same season, the creamy-white trumpet variety, W. P. Milner, is at its best, also the showy and magnificent Sir Watkin, an incomparabilis with all the substance and texture of a giant trumpet. Among bicolors flowering at the same time is the fine Glory of Noordwijk, while that early Leedsii, The Dove, will be little if any behind. In a warm corner those two fragrant Jonquils, the Campanelle and rugulosus, will also be in flower at the same season.

Now the Daffodil season approaches its height with Emperor and Empress, both good enough in quality for the most fastidious and both wonderfully true to flower, giving of their best. Quite different from Empress, though belonging to the same section, is the graceful white and primrose William Goldring. Among the incomparabilis varieties, Beauty and Frank Miles are good and cheap; while of the Barrii flowering with Emperor, Firebrand, Seagull and Gay Hussar are worthy of mention. Excellent cheap and beautiful Leedsii include Ariadne, Bridesmaid, Janet Image, Mrs. Langtry, Mountain Maid and Waterwitch. For grassland under trees or in partial shade the beautiful Queen of Spain is waiting.

Just a little later and the almost white trumpet Mine, de Graaf is in flower, with such Leedsii forms as Duchess of Westminster, Una and Undine, and Barrii varieties such as Conspicuous, Cœur de Lion, Lady Godiva and Royal Star. That beautiful Poeticus variety Horace also flowers now, but is still not cheap enough for most people to naturalise it extensively, but the more starry and fragile ornatus is cheap enough.

Next come the generality of the Poeticus sorts, including Cassandra, Glory of Lisse, Herrick (very fine), White Standard and, a little later, the fine old Pheasant's Eye, Poeticus recurvus. Flowering with this is that excellent late Leedsii Royal Lady. These close the season unless one except the tiny fragrant Jonquil-like gracilis, which flowers quite at the end of May and likes a sheltered grassy bank.

FROM THE WATER'S EDGE. THREE VIEWS AT GRAVETYE MANOR.

ANNUALS, GLADIOLI and PHLOXES

The Fortnightly Meeting of the Royal Horticultural Society.

THE R.H.S. meeting at Vincent Square on August 9 last might have included a "dry-bulb" show, but in view of the lack of support previous shows received, the idea was abandoned and in place of an ordinary meeting was arranged, at which informal exhibits of home-grown bulbs would be welcomed. This enforced abandonment of the annual displays of home-grown bulbs is unfortunate and seems inexplicable in view of the very large acreage devoted to "Dutch" bulb culture in various parts of our islands. It may be that the industry is so thriving as to need no advertisement or assistance. Indeed, it is conceivably so at the moment. It is quite probable that the cut flower trade could absorb the total output. It is so, well and good, though scarcely good enough, for the time will certainly arrive when the supply will exceed this demand. We are well aware that a part of the present output does find an outlet in sales to amateurs for general garden purposes. For this the growers seem to rely on their exhibits of flowers in their season. It seems to us, however, that the flowering season is not quite the right time to impress on potential buyers the great excellence of home-grown Daffodil and Tulip

bulbs. It is just previous to the buying season that the purchasing public begin to consider bulbs. This being so, such an opportunity as that afforded by the R.H.S. shows of dry-bulbs ought to have been of immense value to the industry and on this account we deplore its neglect. It may be that the awards offered by the R.H.S. were not, in themselves, sufficient to induce competition, though a medal award should not be the whole end and aim of a trade exhibitor. At the meeting under notice the only exhibit of home-grown bulbs was from a private garden. Mrs. Wallis Toller, Woodside, Weybridge, sent a collection which included nearly all the spring flowering bulbs that can be grown in this country and although some of the bulbs and tubers were perhaps a trifle small, they were sound and firm and surely deserving of some official recognition.

The floral exhibits were of the usual character, except that Orchids were much fewer than at previous meetings. That two gold medals were awarded is an unusual occurrence at this time of the year. The collection of hardy annuals, sent by Messrs. Sutton, was considered by several of the judges to be the finest that has ever been seen at the hall, though we are inclined to the opinion that

the Reading firm's exhibit of two years ago was even more praiseworthy. On the present occasion it was very beautiful, however, and fully illustrated what a wealth of annuals we may draw upon to make our gardens beautiful at comparatively little expense, even during such an unfavourable season as this. There were annuals for all tastes and for all purposes, though for striking, floral effect it was the handsome baskets of *Lavatera Loveliness* and the large vases of annual *Lupinus* that were so very successful while quieter and perhaps more artistic effect was provided by the Shirley Poppies which, in both single and double forms, included many delightful shades of colour. Marigolds have long been favourite garden flowers and of these there were the rich orange variety of the old-fashioned type as well as the massive double African and the smaller compact flowers of *Legion d'Honneur*. The blue *Love-in-a-Mist* is very well known and was represented by a large vase delightfully arranged, but the white variety was new to many visitors, as also was *Aretotis grandis*, which is really quite an old annual. *Viscaria Pink Beauty* and *Larkspur Pink Pearl* are two very elegant annuals of charming colouring. Space, however, does not permit the mention of a tithe of these gold medal annuals, which included almost every one of those worth growing.

The other gold medal was awarded to Mr. H. J. Jones for a collection of herbaceous Phloxes. At several meetings Mr. Jones has arranged

AN EXTRAORDINARY DUTCHMAN'S PIPE, *ARISTOLOCHIA GIGAS* STURTEVANTH.

A GRAND ADDITION TO HERBACEOUS "SPIRÆAS," *ASTILBE* KING ALFRED

excellent exhibits of this showy and valuable plant and this medal is a very appropriate reward for the whole series. The bright colours of such as C. Edwards, Homeland, Scarlet Gem, Imperator and Jules Sandeau were exceedingly pleasant to look upon during the dull afternoon.

Gladioli came next in importance and of these handsome flowers Messrs. Kelway had the largest collection. They showed a great many of the best large-flowered sorts and also some very graceful *Primulius* hybrids. The latter were especially good in a collection of Messrs. Lowe and Gibson, who had vases of *Zenobia*, *Insurpassable*, *Regulus* and many others, with some large-flowered kinds, among which the remarkably-coloured *Fieldmouse* was noteworthy. Decorative spikes of *Primulius* hybrids were also shown by Major G. Churcher.

Among the border flowers was a good vase of the Californian Poppy, *Romneya Coulteri*, shown by Mr. G. R. Downer, and there were several splendid *Kniphofias* with the elegant *Poterium obtusatum* in a collection by Messrs. M. Prichard and Son. A goodly vase of *Allium sphaerocephalum* was noteworthy in the group arranged by Mr. G. Reuthe. This round-headed species has had a ready sale at Covent Garden lately. It is a native of South Europe, but the bunches on sale were mostly grown in Holland. They were exceptionally vigorous and unless bruised one did not notice the "oniony" smell.

At the end of the hall under the clock were three very distinctive exhibits. Messrs. J. Macdonald and Sons made a pretty little garden solely of Grasses, somewhat on the style of their Chelsea exhibit. Messrs. J. Vert and Sons brought some of the magnificent Hollyhocks for which they are noted. These were all double-flowered varieties, and the tall stems were thickly studded with fully double flowers which possessed the outer "guard" petals without which the old time florist would have spurned any Hollyhock, no matter how beautiful its colour might be. By the stairs Messrs. G. Bunyard and Co., had a small but very choice collection of pot fruits, all illustrating high cultivation. There were Pears, Apples, Plums and Figs, all first rate, and the Pears surpassingly good. The bushes of *Marguerite Marillat* bore immense, perfectly shaped fruits. The varieties of Apple shown were Rival, Rev. W. Wilks and Peasgood's Nonsuch, while of Plums there were Monarch, Late Orange and Victoria.

In another part of the hall Sir James Knott, Bart., Close House, Wylam-on-Tyne, sent from his gardens over sixty dishes of Gooseberries. This was the largest collection that has been seen at the hall for a considerable time and it received a deal of deserved admiration. The large fruited sorts included such well known names as Leveller, Overseer, Speedwell, Collie's Lane Leader and Matchless, and there was also a dish of the luscious little yellow Champagne. Adjoining the excellent Gooseberries there were several dishes of equally meritorious Red and White Currants.

From their Wisley trials the Society sent up specimens of all the Turnip-rooted Beet that received awards of merit and these so impressed the Committee that the collection received a card of cultural recommendation.

NEW AND RARE PLANTS.

***Aristolochia gigas Sturtevantii*.**—A vigorous plant of this tropical climber, bearing a fully expanded flower and several large buds, was shown. The uncommon appearance of the enormous perianth, with its curiously contracted tube and long tail attracted much attention in spite of its unpleasant odour. A good specimen is in flower on the roof of the Victoria regia house at Kew. Shown by Messrs. L. R. Russell, Limited.

***Astilbe King Alfred*.**—This is one of the tallest of the hardy herbaceous "Spireas," the flower spikes rising fully 6ft. in height. The fastigate, almost congested habit of the flower spikes suggests *Astilbe Davidii* parentage. The long plume-like inflorescences are composed of myriads of creamy-white flowers on chestnut coloured stems. An

THE BRILLIANT GLADIOLUS RED FIRE.

admirable plant. Award of merit to Messrs. M. Prichard and Son.

***Astilbe simplicifolia hybrida rosea*.**—In general appearance this is a more vigorous *Astilbe simplicifolia* and so is a valuable garden plant. The rosy coloured spikes were freely borne on a plant in a 5in. pot. A white variety of elegant habit was also shown. The rosy variety was the more robust, but both are quite twice the height of the type plant. Award of merit to Mr. G. Reuthe.

***Asplenium F. f. angustatum medio-decipiens corymbiferum*.**—It was sapiently suggested that this name might, for general purposes, be considerably shortened. The plant, however, is a very beautiful and uncommon hardy Fern. The pleasantly green fronds are about 18ins. long and the ends of the pinnae are delicately crested. Award of merit to Mr. Amos Perry.

***Cattleya Eleanore* var. *Prince of Wales*.**

A well grown plant bearing three good flowers was shown. The sepals and petals are pure white and this is relieved by violet-purple on the broad lip, a yellow disc and lines of the same colour running from the base. Award of merit to Messrs. Hassall and Co.

***Gladiolus Butter Boy*.** A well disposed spike of a *Primulius* hybrid. The flowers are rather less hooded than usual, but the *Primulius* parentage is quite obvious. The colour is pale golden yellow with two narrow crimson lake lines on the lower segment. Award of merit to Messrs. Lowe and Gibson.

***Gladiolus Red Fire*.**—A most brilliant spike of living scarlet-crimson colour. As is the case with the previous variety the flowers are well disposed and they have an unusual amount of substance. Both will be valuable for the garden and as cut flowers. Award of merit to Messrs. Lowe and Gibson.

***Kniphofia C. M. Prichard*.**—A tall stately spike of bright yellow flowers. This is an exceedingly effective variety in the garden. Award of merit to Messrs. M. Prichard and Son.

***Kniphofia Rouge et Soufre*.**—This is the handsome vermilion-scarlet and yellow variety so greatly admired at the previous meeting. Award of Merit to Messrs. M. Prichard and Son.

***Kniphofia July Sun*.**—A long and somewhat slender spike of brilliant vermilion-scarlet flowers. Shown by Messrs. M. Prichard and Son.

***Lewisia Wisley Seedling*.**—This quaint little plant is said to be the first genuine hybrid and was raised from *L. cotyledon* and *L. oppositifolia*. It bears well flowered 6in. to 8in. spikes of widely expanded flowers, which are about 3in. across. They are of creamy white colour with rosy magenta lines, giving a rosy pink effect. Botanical certificate to the Director, R.H.S. Gardens, Wisley.

***Stokesia cyanea præcox Perry's Purple*.**—This is a freer and earlier-flowering variety of the American Aster-like *Stokesia cyanea*. The flowers are nearly 3ins. across and of a dark bluish-purple. An uncommon and attractive herbaceous perennial. Award of merit to Mr. Amos Perry.

A ROSE TRIAL GROUND FOR WISLEY

THE Council of the Royal Horticultural Society has, we are informed, decided to establish a plantation of Roses in order to compare the behaviour of different varieties in the garden. The Council regrets that in spite of long negotiations, the National Rose Society has not seen its way to co-operate, but a confident appeal is made to rose growers for assistance in making this effort a success. A portion of the newly acquired farm land at Wisley has been set aside for the purpose, providing ample room with space to expand in the future, and while the primary object of the plantation will be the testing of new varieties of all classes against well known standard varieties, it is hoped also to increase the collection of Rose species which is already considerable. The varieties planted will be reported upon at intervals and awards will be made according to their value for use in gardens. The tests will be made, as a rule, with not fewer than six plants of each variety and all varieties sent for trial should reach the Director, R.H.S. Gardens, Wisley, Ripley, Surrey (if by rail, L. and S.W. Railway, Horsley Station), on or before November 15. The necessary forms for entering new varieties for the trials can be obtained from the Director, who will also be glad to receive offers of standard varieties for planting for comparison. It is hoped that this Rose trial ground will eventually be developed into a National Rose Garden for Great Britain, where Roses of all types will be well represented.

WINTER GREENHOUSE PLANTS

Only when it is too late to put things right will many cultivators realise that timely attention to winter-flowering plants was not given, and that as a result the greenhouse will not be as gay during the dull days as it might be.

THROUGHOUT summer and early autumn the gardener is, generally, very busy indeed and can rarely find time to pay attention to anything beyond current work. It is, in fact, always "harvest time" with the gardener and rarely, indeed, will work "keep" even for a few days without something going wrong.

At this season, however, it is well to look ahead and spend a short time now and again preparing plants for placing under glass; the reward for such work will come in due course.

Plants now outside, such as Azaleas, Arum Lilies, Genistas, Acacias, Libonias, Zonal Pelargoniums and the berried Solanums, first need consideration. All the hard-wooded plants, such

matter before that date. All very hairy-leaved plants must be syringed where necessary and not sponged. When engaged in watering the plants, closely observe how the water percolates through the soil; if freely, the drainage must be satisfactory; if it remains for some minutes on the surface of the soil the drainage should be examined by carefully turning out the plants, and any obstruction found should be removed.

Chrysanthemums should be housed before the flower petals begin to unfold; if left out night-dews and rain will cause decay of unfolding blooms. All plants that are to be retarded should be placed on ashes, slates or tiles on the north side of a wall or fence. Plants of all kinds needing stimulants should receive gradually weakening doses

till towards the end of September. During mild weather and while early and late dews prevail fully expose these plants and Cyclamen, as such treatment is most beneficial. GEORGE GARNER.

ANNUALS UNDER GLASS

JUST now, when annuals in the garden are giving of their best, my mind goes back to the spring months when many of them in pots were even finer. Safe from extremes of any kind, in a cool greenhouse or conservatory, they are encouraged to grow much taller than when in the open, and this reflects upon the flowers as to improve them almost beyond recognition, and an effect is produced which is not, in floral beauty, eclipsed by anything later in the season. In this lies the reward of sowing in August and September. Some prefer to wait until the new year, but only in rare cases do the plants equal those which have been given a longer growing season.

The culture of annuals in pots may be managed by anyone in possession of a slightly heated frame or greenhouse. In fact, in the matter of heat one can be too kind. Cool, comparatively dry and airy surroundings, with all available light when days are short, are what annuals must have to keep them dwarf and strong. Until November, fuel is wasted upon them, and it is the same in an average spring, from April onwards. In the period between, a temperature of from 45° to 50° Fahr. is ample.

Excepting Schizanthus, which are best sown about the middle of the present month, the remainder of those to be named here are best sown in September. Schizanthus require pricking out; the others, being more or less tap-rooted, succeed better when not put to this strain, and therefore need not be sown so early. In the initial stages a rich soil is not desirable, for over-luxuriant growth is very liable to damp off in the depth of winter. A poor soil makes for wiry plants and such as are capable of resisting ordinary extremes. Fibrous loam, with just a little leaf-mould, and enough coarse sand to ensure porosity, make a suitable compost. The details of sowing and potting have often been repeated and need not detain us. Pot off the August-sown plants singly into 5in. pots as soon as they are fit to handle. In the same size sow a pinch of seed of the other kinds, subsequently thinning the resultant plants so as to leave three or four to stand the winter. This is merely a precaution against accidents, for one, or at most two, is all that will be required at the final potting. A cold frame is the ideal place for the plants until October. Afterwards a shelf near the roof glass in a cool house is most suitable. In this position all that the slender roots call for is sufficient water just to keep them going. To give more than this is to court disaster. There are many days in winter when it will be possible to open the ventilators without creating draughts, and these opportunities should be fully utilised.

With the turn of the year Schizanthus will be well enough rooted to go into 5in. pots, and later into 7in. One shift into 6in. will best suit the remainder. A little old manure may be added to the compost at this stage, and in potting discretion should be exercised in the use of the rammer. Potting should, in any event, be deferred until it is seen that the plants are responding to the lengthening days. Some prefer to pinch the growths occasionally, but this is really not essential, and the operation may be left to individual discretion. As the plants increase in height they

A MOST USEFUL GREENHOUSE PLANT, PRIMULA MALACOIDES.

as Azaleas, were potted into larger pots several weeks prior to their being placed outside, or should have been repotted then; if they were not so dealt with there must not be any repotting of them now. The great thing is to have all plants quite clean when they are placed under glass in autumn, the leaves and stems free from soil, sediment and insects and the pots clean and free from weeds.

All growers of these plants are not able to house their stock in early autumn because room is unavailable, but, where early housing is practicable, it is desirable to carry out the work in good time. The colder nights chill the plants, so that many leaves fall off before Christmas; this is especially the case with Salvias.

There are two ways of cleansing the foliage, namely, by syringing and sponging; and after August 25 it is not good for the plants to be syringed, so close attention must be paid to the

week by week until housing time. After housing, none should be given for a week or so. Even clear water will be needed less frequently than during August. For a time it will be beneficial to the plants if free ventilation be the rule, with, maybe, a light shade during very bright sunshine.

POTTING PLANTS.

There are some kinds of plants, such as Arum Lilies, Chrysanthemums, etc., which have been planted out, that must be lifted and potted. This work should be done carefully, and a rather fine compost of average richness will be found helpful, also moderately firm potting. Some shade for a time is essential till the roots take to the new soil and begin to permeate it freely. Quite cool treatment is correct in their case; it would be a mistake to introduce them forthwith to artificial heat.

Plants of Primulas, Cinerarias and Calceolarias are, of course, in frames and should be kept there

will need a position on the side benches, and should be provided with neat stakes. A little fertiliser sprinkled over the surface of the pots when the latter are full of roots will be helpful.

Follows a description of some of the most reliable annuals for the purpose suggested.

Among Schizanthuses there is wide diversity of form. The Wisetonensis type is one of the oldest, valuable for its compact habit of growth, its freedom to flower, and wide range of colouring. In size, however, the flowers do not equal those of the hybrid types. Nearly every well known firm has its own strain of these, and it is only by actually seeing them in bloom—as, for instance, at Chelsea—that one realises of what these plants are capable. In the retusus section the flowers are almost orchid-like and in many shades.

Clarkias, perhaps, come next in importance. They make handsome pot plants up to 5ft. high from autumn sowing, and they cover themselves right from the base with brilliantly coloured double flowers in long loose sprays. The elegans varieties are those required and they may be had in salmon scarlet, pink, white, purple and rose.

Salpiglossis. It is only of quite recent years that the value of this annual for conservatory decoration has become realised, but it is rapidly gaining favour, since it has proved to be quite as easy to manage as any of the older kinds, and more striking than some. The colours vary through shades of yellow, red and purple, blue and gold, and crimson and gold, and the large funnel-shaped flowers have an exquisite velvety texture which well displays the colouring. When well grown the height is about 3ft.

Phlox Drummondii is also worthy of a place, for it makes a charming pot plant, and there is a variety of colour in sweet-scented flowers. Sutton's

Purity is exceptionally good, being pure white, and usually at its best about Eastertide. Pink Beauty and Fireball, a pleasing red, also are useful.

Nemesias of summer bedding fame are invaluable, for while there is no lack of tall growers, dwarf kinds are scarce. In a good strain the colours and markings of the flowers are remarkable and defy description.

Sweet Peas are, beyond all question, the finest annuals we have, and equally as reliable under glass as any. The only difference in the routine of cultivation set forth above is that these plants can be wintered safely in a cold frame until January, when they are brought indoors and potted in 12in. pots, or planted out, as the case may be.

Other suitable annuals include Mignonette, Nicotianas, annual Chrysanthemums, Godetias and Aloxsoas. J. T.

CORRESPONDENCE

LILIES FROM SEED.

ON page 388 your correspondent M. L. W. deplores the fact that *Lilium candidum* does not seed in this climate. I had always believed this to be so, but a few years back, in 1917, I think, a friend sent me a few pods of seed gathered in Salonica. From these I raised seedlings which again produced seed in their turn, which germinated well. But this year the strain is not setting seed well and I think it very possible that in this country it may gradually fall into line with our old strain of

suitable evergreens in winter. *V. Traversii* is a quick grower and can be raised from seed and cuttings, which fact atones for its refusal to shoot out healthily after being cut back. This evergreen will succeed in most soils, in sun or shade, though too dense shade will much hinder its flowering worth.—C. T., *Amphill*.

AN INTERESTING PALM.

YOU may be interested to hear that two rather unusual plants are in flower in Cheltenham, both in the public street. In St. George's Road two tall plants of *Dracaena indivisa* have borne large spreading heads of flower, and in Queen's Road a plant of *Phormium tenax* has thrown up four flower spikes some 8ft. in height, bearing many of its dull red flowers widely spaced on the stems.—J. P.

[*Dracaena indivisa* is a synonym for *Cordyline australis*, a plant of which, flowering outdoors near Madstone, was figured in last week's issue.—Ed.]

ROSES FOR WALLS.

IN my journeyings abroad I see many Roses on house walls which cannot be considered well placed. Dorothy Perkins seems to be an especial favourite for this purpose, but surely it has many drawbacks. To train it properly it is necessary either to wire the walls—an expedient I do not like—or to be continually driving in fresh wall-nails, which is destructive of the fabric. Then again there are so many places where one may plant the Wichuradana Ramblers effectively that it would surely be better to reserve house walls, many of them, naturally, having a southerly aspect, for choicer climbers, such as the many fine climbing Noisette, Tea and Hybrid Tea Roses, to say nothing of other beautiful and not over hardy shrubs which would succeed there. Especial favourites of mine are the small flowered but wonderfully graceful Bankstan Roses, but how seldom, nowadays, does one see them! If less striking as regards colouring than Dorothy Perkins, how much more beautiful are they as regards pleasing form and gracious arrangement of blossom.—MIDLANDER.

HOW TO TRAP MOLES.

HAVING read your reply to N. P. H. (August 5, page 362), on "How to Trap Moles," may I give some results of my experience in a garden infested with moles? Chose a place for your trap in a tunnel between two mole hills. Open a moderate hole with a trowel as cleanly as possible and leave it smooth and firm where the mole is to pass. Set the trap as near the middle of the tunnel as you can judge, and place flat crocks or stones on the right and left hand at either entrance to the trap, so disposing them as to guide the mole into its jaws. Cover the opening with turf or anything handy. You must be careful not to let any loose earth fall into the hole, nor to tread in the tunnel anywhere near the trap. Otherwise the mole will heave the obstructing earth before him and so spring the trap without hurting himself. I do not find that the mole pays any attention to the taint of the human hand used in smoothing down the surface of the tunnel and in handling the trap, nor is he scared by the gleam of daylight from above. The fact seems to be that the mole, having no natural enemies underground, is the most unsuspecting beast in the world. You may tread heavily close to the spot where he is heaving up a molehill provided you do not tread on his tunnel, without causing him to stop work. A more suspicious beast would pause on finding an obstruction of unusual shape and material barring his

THE YELLOW BANKSIAN ROSE.

candidum and become sterile.—F. HENNEPI CHAPMAN, *Rvc.*

A GOOD EVERGREEN SHRUB.

OF the large and varied genus *Veronica*, *V. Traversii* is one of the hardest of the shrubby section and, when well flowered, one of the most showy. We have several quite large specimens here—the best being about 10ft. to 12ft. across and 6ft. to 7ft. high—and though they have now, the last week in July, just passed out of flower, no shrubs could have been more effective, so massed with blossom were they. The short spikes of bloom stand up well above the box-like foliage, while the individual flowers are of a pale mauve shade. When not in flower this shrub can be said also to be reasonably attractive in growth and leafage, while pieces of the latter are not to be despised by the floral decorator when looking for

path. Not so the mole. He wrestles with it until it gives way, and thus his very fearlessness is his undoing. The conclusion is—set your trap so that the mole has an unobstructed pathway into its jaws and his destruction is certain.

I have also got rid of a mole, before he had had time to make many tunnels, by playing pieces of carbide of calcium in the latter, but where a plot of ground is riddled with a network of runs this method is not successful.—A. C. C.

THE RASPBERRY AS A SAPROPHYTIC PLANT.

WHILE walking round a pool in Cannon Hill Park, Birmingham, the other day, a considerable amount of plant growth was noticed on an old branch of a tree (probably Ash), which has been lying partly covered in shallow water for a number of years. On examination, the plants proved to be the common wild Raspberry (*Rubus Idaeus*, Linn), together with some hardy Ferns and a few varieties of Grasses. A few of the plants were lifted, the roots of which had permeated the decaying bark and cortical tissues. No soil could be seen and, it might be added, very little decaying matter had been collected. The plants appear quite healthy and are growing just above the normal water level. They are fruiting well.—ETSON.

IMPROVING THE ROCK GARDEN.

THE rock garden is now a regular feature of most gardens, and is the part which often has the greatest share of its owner's affection and attention. Yet people are still heard to regret that its beauty is comparatively short-lived. They speak of it as a part of the garden to be enjoyed in the months of May and June only, except for little specimen plants dotted about, which are interesting from a gardener's or botanist's point of view, but not generally attractive or effective in colouring. This is chiefly the case because it is not generally realised that by a careful selection of plants the charm of a rock garden may begin with the first mild spell of weather in the new year and continue until the autumn frosts become severe.

Lithospermum prostratum, *Alyssum saxatile*, *Arenaria montana* and *Aubrieta*, which form such gorgeous patches of blue, yellow, white and mauve that they are admired by all who see them, will find serious rivals early in the year if *Chionodoxa sardensis* or *Scilla sibirica*, *Eranthis hycnads*, *Galanthus nivalis* or *Leucopium vernum* and *Crocus Sieberi* are planted in drifts. These are quite as easy to grow if equal attention is paid to their tastes in the matter of soil and position, and the only difficulty will be to choose a place where their leaves can be left to mature and furnish the bulbs for the next season.

In similar fashion the rock garden may be made a place well worth visiting in the autumn if *Gentiana Farreri*, *Cerastostigma plumbagnoides* and *Crocus speciosus* are planted with a somewhat lavish hand, all of which are easy to grow and propagate. The late summer season can be provided for by free plantings of Alpine *Dianthus* in variety and of several kinds of the smaller *Campulanas*, a selection of both of which may easily be made from any of the horticultural trade catalogues dealing with this class of plant.

The following may also be relied upon to give pleasure and satisfaction: For the early part of the year, *Hyacinthus azureus* (often the mistle of the season), *Anemone blanda*, *Crocus Imperati*, *C. bulbosus*, *C. Susianus*, *Saxifraga apiculata*, *S. Burseniana*, *Adonis amurensis*, *Cyclamen coum*, *Iris reticulata*, *I. r. var. histrioides*, *Primula denticulata* and its varieties, *Helleborus niger* and *H. orientalis* in variety. For the autumn, *Crocus zonatus*, *C. longiflorus*, *Sedum*

spectabile, *Schizostylis coccinea* and *Colchicum* in variety (where there is room for their large leaves to develop in the spring). Where there is space for small shrubs the following should be included: *Rhododendron dauricum* or *micro-latum*, *Daphne Mezereum* (both the white and the pink forms), *Zauschneria californica* and *Cotoneaster horizontalis* for its berries.

As the best season for making alterations and additions to the rock garden is approaching, it would be wise to decide what is to be done without further delay, so that the plants and bulbs may be got in early in September and get established before the cold weather; indeed, it will be better if the bulbs are planted at once. They will do better and flower earlier.—A. E. W.

WHY "AMETHYSTINE"?

CAN any reader of THE GARDEN explain the meaning of the word "amethystine" which frequently occurs as the specific name of some plant with blue flowers? No doubt it is in consequence of its being so used in botanical names that we often see in trade catalogues the colour of some plant that has flowers of a good pure blue described as a "brilliant amethystine blue." Why amethystine? An amethyst is a gem whose colour is distinctly a reddish purple: except in the best examples a rather light or washy reddish purple. It is certainly no compliment to a flower of pure blue colour to compare it with that of an amethyst. It sounds like a slip-slop or boggle of terms. How did it arise, and when and why? Was it originally a slip of the botanist's pen, or of his intellect? Did he perhaps mix up amethyst and sapphire? Sapphire is certainly a pure blue, and yet I cannot remember seeing it applied to a flower as a colour word. And if it is merely an error of ignorance or carelessness, how is it that it has gone on without correction until it has become so familiar that, without accepting it as a correct colour definition, one knows that when the word amethystine is used it is meant to denote something blue either of flower or stem?—G. J.

THE JAPANESE WISTARIA.

IT is quite remarkable to notice how little this very desirable plant is known in gardens, especially in the northern parts of the kingdom. It is decidedly a hardier and less requiring plant than the universal Chinese Wistaria that everyone knows and admires, and yet one may go to garden after garden and nursery after nursery and never find one specimen to look at or to buy! Wistaria multiplex, the Japanese Wistaria, has several advantages over the Chinese form, in that it will thrive in strong, cold calcareous soils where the Chinese plant can hardly exist, and it is not only hardier, but later in its flowering period, so that it often escapes the frost that cuts off the earlier sorts. In the North of England it is really the most reliable and hardy climber, flowering more freely on an exposed pergola and in more adverse conditions of weather than the well known Chinese plant. The flower racemes are much longer than the Chinese Wistaria, and the flowers are decidedly smaller. The colour varies considerably, as does also the length of the clusters of bloom, because this variety seeds abundantly in many parts and especially in Japan, therefore propagation is made by seedling plants rather than by the much more tedious method of layering. This, however, has a drawback, and that is that the seedlings vary greatly, so that one can never be sure if one will get a good or an inferior variety. The very finest and richest coloured varieties are to my mind even more beautiful than the Chinese plant we all love. The white flowered form is specially desirable, as not only are the racemes of great length

and purity of colour, but they are three weeks later than the coloured forms, while the white-Chinese form is earlier than even this type, and almost always suffers in consequence. The Japanese forms also have the advantage of the leafage being more advanced, so that the racemes of flowers are set off by the green foliage.

If nurserymen will propagate only from the finest types the Japanese send over, I think the public would soon be convinced of the value of the Japanese Wistaria. As it is, it is disappointing to buy a plant that turns out an inferior variety, pale in colour and short in raceme, whereas the raceme should be a yard long and of a richer colour than the Chinese. As for the white it is at its best far superior to any of the Chinese white forms.—E. H. WOODVALL, *Scarboro'*.

SWEET PEAS & ROSES AT GLASGOW

THE third annual exhibition of the Scottish Sweet Pea, Rose and Carnation Society was held in the St. Andrew's Halls, Glasgow, on August 2 and 3. Notwithstanding the unfavourable weather experienced in Scotland this summer, the promoters had every reason for congratulation on the success which attended the Show. In every class, with the exception of that for Border Carnations, the entries showed a considerable increase over those of last year. The quality of the exhibits was of rare excellence, and one seldom sees Roses and Sweet Peas exhibited in such fine condition. Competent judges expressed the opinion that the Scottish Show was a good way ahead of that held recently at Eastbourne by the National Sweet Pea Society.

The prize offered for the best six blooms of new varieties of Sweet Peas was awarded to Mr. John Smellie of Helensburgh.

There was keen competition for the Burpee Cup, as most growers seemed keen to secure this trophy. It was won by Mr. George Bowness, Busby, who staged twelve vases of distinct varieties, all fine outstanding blooms, the most noticeable being Austin Frederick Improved, Private Jack Smellie, Mrs. Bowness, Picture and Hercules. The second prize went to Mr. James Paul.

Mr. Bowness was also leading winner in the class confined to nurserymen. In the Amateurs' Section the individual exhibits were well grown and attractively staged. A group of nine vases shown by Mr. James Paul, Killearn, gained the first prize here, and the same exhibitor also carried off the Eckford Cup.

Roses were also specially fine, the gold medal for the best bloom in the Show being awarded to Messrs. Hugh Dickson, Limited, Belfast, who were also winners of the Polytechnic Cup for thirty-six blooms of Roses. In the Amateur Class the class for twenty-four distinct varieties was very keenly contested, first prize going to Mr. J. E. Turner, Gourrock. The cup for blooms in the Amateur Section was won by Mr. James Kerr, Stewarton, with splendid specimens of Mrs. Foley Hobbs. While for three vases of distinct varieties, Mr. J. G. Williamson, Giffnock, was awarded the Turner Cup.

Among the trade exhibits, Messrs. Dobbe and Co., Edinburgh, displayed a fine collection of Sweet Pea blooms which included, among others, Hawmark Tangerine, Picture, Majestic, George Sawyer, Royal Purple, Dorn, Renown and Melba.

Messrs. Lowe and Gibson, Crawley Down, Sussex, staged an attractive collection of Gladiah, also of Border Carnations and other flowers. J. McG.

GARDENING OF THE WEEK

FOR SOUTHERN GARDENS.

The Kitchen Garden.

General Work.—The month of July was an excellent one for getting the main supplies of all the Brassica family established and all look promising. If not already planted and room can be found there is still plenty of time for putting in Coleworts and the Portugal Cabbage (Couve Tronchuda). The latter may, with advantage, be more extensively used where large kitchen supplies are always required, for it may be generally relied upon to stand the winter well. This Cabbage not only provides acceptable hearts for using, but the mid-ribs taken from the large leaves are an excellent dish and should be cooked in the manner of Sea Kale. As it is a robust grower on well worked soils, a distance of 2ft. should be allowed between the rows and 18ins. between each plant. For Coleworts, about 20ins. is enough between the rows and 15ins. from plant to plant. Leeks for late use should be got in as soon as possible, dropping them in holes made with a long dibber or bar of sufficient depth to allow for a well blanched stem. Keep the hoe going as much as possible between developing crops.

Lettuce.—Besides sowing some of the recognised winter varieties, some seeds of early maturing kinds should be sown on a warm border, taking care to sow thinly and thin early. Given an open, favourable autumn some useful salading will be available until quite late from this sowing.

Endive.—Any necessary thinning or transplanting should be seen to before the plants become crowded or drawn. Where the plants are remaining in drills where sown thin out to about a foot apart. Water should be afforded during dry weather.

The Flower Garden.

Rambler Roses.—These plants should be overhauled as soon after the flowering period as convenient. The pruning chiefly consists in the cutting away of as much as can possibly be spared of the old flowering wood. This will concentrate the energies of the plants upon next season's flowering growths, and should these be weak and unsatisfactory much may be done to improve them by the end of the season by giving a few copious waterings with liquid manure water.

The Hardy Fruit Garden.

Summer Fruiting Raspberries.—Remove the nets as soon as the crop is cleared and cut to the ground all canes that have been bearing fruit this season, also any weakly new growths which are not required. With so many pressing operations on hand at this season of the year it may not be possible to stop and regulate next year's fruiting wood, but care should be taken that this is sufficiently secure against damage by wind or other agencies. Should autumn fruiting varieties be grown, see that the nets are in position at once if not already done.

Gooseberries.—The season of these fruits for dessert purposes may be considerably lengthened by planting trees in a position with a northerly aspect. Where a portion of a wall can be spared for cordons, they do well and give a supply of fruit for many weeks after gathering is over from trees in warmer aspects.

Vines.—Keep all lateral growths well in subjection so that plenty of air and sunshine can penetrate, without which it is impossible for the Grapes to finish as they should. Feed the plants liberally if carrying good crops and protect all bunches from birds and wasps, etc.

H. TURNER

(Gardener to the Duke of Northumberland),
Albury Park Gardens, Guildford.

FOR NORTHERN GARDENS.

The Kitchen Garden.

Brussels Sprouts.—Where "autumn sowing" is practised the work may be carried out now. Sow thinly in rows 12ins. apart and leave in the seed bed until spring. Brussels Sprouts stand the winter well in most districts. It is always wise to accord them a sheltered site when in the seedling stage, as cutting winds prove more harmful than frost.

Savoys also may be sown now and treated in like manner to Brussels Sprouts.

Cauliflowers.—A small sowing of Early London and Walcheren may be made now in the open. In northern gardens it is wise to prick out the

seedlings at a later date into a cold frame and winter in this way. In more favourable localities the remainder may be pricked out at the foot of a south wall and afforded some shelter during severe weather.

Celery will be growing apace, and forward hatches will now be ready to be partly earthed up. Clear away all superfluous or decayed growths from around the heads before earthing up takes place. Encourage late crops by waterings of liquid manure.

Tomatoes.—In pits where early crops are about past, the plants should be cleared out at the first opportunity and the structure thoroughly washed in readiness for the reception of other plants. Save the soil that the Tomato plants have been growing in, as this, if stored in an open shed, will prove useful in the spring for numerous purposes—being rich in various unexhausted qualities, and finely adapted for potting purposes where Dwarf Peas and French Beans are forced.

The Hardy Fruit Garden.

Strawberry Runners.—Where these have been rooted in small pots for spring forcing they may now be litted in preparation for moving into their fruiting pots. When potting, use a rich loamy soil and place the pots on a layer of sifted ashes in an open situation. Spray the foliage freely with clear water on warm afternoons.

Gooseberries and Currants.—Remove the nets from these immediately the crops are gathered and use the Dutch hoe freely among the bushes where the surface soil is caked. This will assist in keeping the ground clean and porous for the remainder of the season.

The Flower Garden.

General Work.—The time is not far distant when preparations must be made for securing the necessary stocks of various plants for filling the flower beds next season. Cuttings of Geraniums, Heliotropes, double and single Marguerites, Fuchsias, etc., should be secured and rooted at an early date. Geraniums and Marguerites root best when allowed plenty of air, just shading from the strongest rays of the sun. Place the boxes along the foot of a sheltered wall and remove to safe quarters on the first indication of frost.

Climbing Roses.—Tie in the strong young growths necessary for replacing older wood. Remove others not likely to be required and water thoroughly with liquid manure so that the plants may be further invigorated.

Mixed Borders require frequent attention at this time if tidiness is to be maintained. Additional staking and tying will be necessary or the autumn gales will cause considerable damage among the taller growing plants. Cut back or trim plants as required and keep weeds in check.

Sweet Peas.—Owing to the continual wet Sweet Peas have grown to an unusual height this season, and in many gardens it will be found necessary to augment the existing stakes. Where the plants are in rows, strong poles may be inserted every few yards and several rows of binder twine stretched between them.

JAMES McGRAN

(Gardener to Sir Henry H. Houldsworth, Bart.),
Coodham, Kilmarnock.

GREENHOUSE AND CONSERVATORY.

Dimorphotheca Ecklonis.—This attractive South African plant is very useful for the greenhouse during spring and early summer. It is easily propagated at this time by means of cuttings placed in a case in a cool house. The young plants require frequent stopping to induce a bushy habit, but this should not be done later than January, as this plant has a definite flowering season and if stopped later than this the chances are that no flowers will be produced.

Dendromecon rigidum.—This beautiful Californian Poppywort, although hardy in the south and west when planted against a wall, should be especially in the colder parts of the country, more generally planted in the cool conservatory or greenhouse. The other week I saw a splendid specimen of it in the nursery of Messrs. R. Veitch and Son, Exeter, where it was planted against the back wall of a cold greenhouse. This plant is generally regarded as being difficult to propagate, but I have never found any difficulty in rooting it by means of short twiggy shoots, inserted in pots of sandy soil, standing them under a bell glass in a cold house. Like most plants of this order

it does resent disturbance at the root and great care must be exercised when potting off the young plants.

Aristea (Witsenia) corymbosa is a beautiful blue-flowered plant hailing from South Africa, and belongs to Iridaceae. It is unique in this order in that it is hard and woody in character. It is by no means an easy plant to propagate, but is best done by means of cuttings inserted some time during this month. They should be put into pots of fine sandy peat, and stood under bell glasses in a case in a cool house. If the cuttings are taken from healthy plants there should be little difficulty in rooting a good proportion of them. Here, as in the propagation of all choice plants, the covering glasses should be wiped dry every morning. This plant grows well in a compost of sandy peat, using it in a rough and lumpy state for the older plants. Ample drainage must be given and careful watering is essential at all times, as the fleshy roots are apt to be injured by over watering.

Pimelias include quite a number of desirable greenhouse plants, but at the present day very few of them are in cultivation. Some of the best are *P. P. ligustrina*, *spectabilis*, and *ferruginea*. The two former species make fine specimens if planted out in a well drained bed in the cool conservatory. They grow well in a compost consisting of sandy peat and a little good medium loam. After flowering they should be trimmed back so as to keep them close and well furnished. *P. ferruginea* also does well when planted out, and it is the best species for pot culture, being of a compact, bushy habit. It produces its rose red flowers in great profusion. Good plants can also be grown in quite small pots. *Pimelias* are easily propagated by means of cuttings during the spring months, and again during August, when plenty of good cuttings are available, as the plants are completing their growth. As is usually the case with woody plants of this character, short twiggy shoots are best for cuttings, and they usually root readily in pots of sandy peat, covered with a bell glass and stood in a cool house. Really the best conditions for rooting all or most of the so-called hard-wooded greenhouse plants, is a case with slight bottom heat, but with no top heat in the house. In the absence of such ideal conditions a cool house is best for propagating this class of plant, the process of rooting taking, in most cases, a little longer.

Ericas.—Most of the greenhouse Heaths may be successfully propagated during this month, as plenty of cuttings in the right condition can usually be got at this time. They will all root in fine sandy peat, and the cutting pots should be carefully prepared, being at least half filled with drainage. The soil should be rammed very firm and the surface of the pots covered with clean silver sand. The required number of pots should be prepared the previous day, watering them well to settle the soil and thus have it in suitable condition for the reception of the cuttings. The condition of the soil is important, otherwise it is by no means easy to firm the very small cuttings that are used. I have frequently seen amateurs insert cuttings in too dry soil, with the result that when they watered them in air bubbles would lift the majority of cuttings up again. Cuttings must be made from the very small twiggy growths, taking them an inch or even less in length. The leaves should be carefully trimmed off and with some practice this is best done with the thumb and finger, but of course the knife must be used for varieties where the leaves do not rub off readily. The cuttings should be carefully dibbled into the prepared pots, afterwards watering them well in with a fine-rosed can and covering with bell glasses. The above remarks may be applied to the propagation of most hard-wooded greenhouse plants.

J. COULDS.

Royal Botanic Gardens, Kew.

FORTHCOMING EVENTS.

- August 22.—Royal Horticultural Society's Fortnightly meeting.
- August 23.—Westerham Horticultural Society's Annual Show. Helensburgh and Goreloch Horticultural Society's Annual Show. Highland Horticultural Society's Annual Show.
- August 24.—Aberdeen Flower Show (3 days).
- August 25.—Dumfries Horticultural Society's Show (2 days).
- August 26.—Dumfries and District Horticultural Society's Show. Ulverston Garden and Allotment Holders' Association Annual Show.

Trials of Violas at Wisley.—The following awards have been made by the Royal Horticultural Society to Violas after trial at Wisley.

AWARDS TO BIDDING VIOLAS.

Award of Merit.—Snow Queen, sent by Messrs. Dobbie; Purity and Snowflake, sent by Messrs. Forbes. The above three varieties bracketed as practically synonymous. Swan, Mary Burton and Archie Grant, sent by Messrs. Dobbie; Lady Knox, Mrs. Alsop and President, sent by Messrs. Forbes; W. H. Woodgate and J. B. Riding, sent by Messrs. Dobbie and Messrs. Forbes; Royal Sovereign, sent by Mr. Stark; Dr. McFarlane and Dorothea, sent by Mr. Crane; Red Edina, sent by Mr. Searlett; Moseley Perfection, sent by Messrs. Dobbie, Messrs. Forbes and Messrs. Harrison; Margaret Wood, sent by Messrs. Artindale and Messrs. Dobbie; Maggie Mott, sent by Messrs. Forbes, Messrs. Dobbie and Mr. Crane.

Highly Commended.—Blanche, Primrose Dame, Bertha, John Forbes, Wm. Daniels and Jackanapes, all sent by Messrs. Forbes; Kingcup and Kitty Bell, sent by Messrs. Dobbie and Messrs. Forbes; Walter Welsh, sent by Messrs. Dobbie; Langeme Harrison, Pride of Damas and Anne Lobson (the last two bracketed as practically synonymous), sent by Messrs. Harrison; Bertha, Newton Mauve and Peace, sent by Mr. Crane; John Quarton, sent by Messrs. Forbes and Messrs. Harrison; Mauve Queen, sent by Messrs. Dobbie, Messrs. Forbes and Mr. Crane; Alexandra, sent by Messrs. Dobbie and Messrs. Artindale; Admiral of the Blues and Mrs. Moss, sent by Mrs. Dobbie and Mr. Elliott. The above two varieties bracketed as practically synonymous. Councillor Waters, sent by Messrs. Artindale; Dindryan, sent by Messrs. Dobbie and Mr. Crane; Mrs. Chichester, sent by Messrs. Forbes and Mr. Crane; Admiration and Jubilee, sent by Messrs. Forbes and Messrs. Dobbie. The above two varieties bracketed as practically synonymous.

AWARDS TO VIOLAS FOR EXHIBITION.

Award of Merit.—Master Banks, Nurse Cavell and Bessie Ferguson, sent by Messrs. Harrison; Mrs. Jas. Smith, sent by Messrs. Artindale; Mrs. J. Lawrence, sent by Messrs. Forbes; Moseley Perfection, sent by Messrs. Forbes, Messrs. Dobbie and Messrs. Harrison.

Highly Commended.—Criss Littlejohn, Mrs. Andrew Stevenson, Mrs. D. Stevenson and Mrs. McEwan, all sent by Messrs. Harrison. The last two varieties bracketed as practically synonymous.

AWARDS TO VIOLETTA TYPES OF VIOLA.

Award of Merit.—Violetta, sent by Messrs. Forbes and Messrs. Dobbie.

Highly Commended.—Princess Mary (Violetta), Gold Crest Violetta and Queen of the Year (Violetta), sent by Messrs. Forbes; Lyric (Violetta), sent by Messrs. Dobbie and Messrs. Forbes.

AWARDS TO VARIETIES OF VIOLA GRACILIS.

Highly Commended.—V. gracilis J. B. Taylor and V. g. Lady Crisp, sent by Messrs. Clarence Elliott; V. g. Purple Robe, sent by Messrs. Dobbie.

Trial of Carrots at Wisley.—The Royal Horticultural Society will carry out a trial of Carrots growing in frames during the coming autumn and winter. The Director, R.H.S. Gardens, Wisley, Ripley, Surrey, will be glad to send entries to those desiring to enter varieties for this purpose and one packet of seed of each variety should reach him on or before August 31.

For Rock Garden or Border. That Argentine one, *Verbena venosa*, is worthy of wider appreciation than it now receives, for not only are its corolla petals purple flowers, raised on stiff 15-in. stems, beautiful, but they are borne during August and September, when colour is none too plentiful in the garden. For the margins of borders, *V. venosa* is

probably the hardest of its race, a true perennial and one that in a free soil will withstand severe frosts without injury. It is, moreover, practically immune from mildew and looks bright and cheerful in the dampest of autumn weather. In very cold localities, or on uncongenial soil, the roots may be lifted and stored in a cold frame over the winter. Propagation is easily affected by off-sets, but the plant produces seed freely and will often appear self-sown in gardens where the soil is warm and gritty.

A Quaint Scabious.—Often catalogued as *Pteroccephalus Parnassi*, *Scabiosa Pteroccephala* is a noteworthy plant in the August rock garden, making a dense cushiony mass of grey, hoary foliage which forms an admirable setting for the large, rosy-lilac pin-cushion-like flowers which are raised just clear of the leaves. It is a plant of the easiest culture in any light soil in full sun, and though it is apt to suffer in winter it is seldom killed outright. It hails from Greece.

A Late-flowering Azalea.—A Californian species, *Azalea (Rhododendron) occidentalis* will thrive in any non-calcareous loam and it does not object to the half shade of woodland trees. It makes a good-sized bush and is particularly valuable on account of the fact that it does not bloom until most of its kind have gone over. In some seasons it may open its white, or pinky-white, sweet scented flowers soon after midsummer, but the normal season of blossoming is late July. The broad, glossy leaves are shed in autumn and the shrub appears to be perfectly hardy. By using it in hybridisation with earlier kinds, *R. occidentalis* has been very instrumental in extending the flowering season of this beautiful race of shrubs.

ANSWERS TO CORRESPONDENTS

FLOWER GARDEN.

STOCKS AND ANEMONES DYING (C. B. R., Berk.).—The mellow on the roots of the Stocks our correspondent has examined may be the cause of the plants dying, in which case very little can be done. The specimen of Anemone sent was too dry on receipt to furnish any reliable information. The blackening of the stem may be due to trying conditions of temperature, while the root looks stunted and ill nourished. If our correspondent cares to send further specimens packed in damp moss, we might be in a better position to advise.

TREES AND SHRUBS.

CYPRESS TREES DYING (A. W., Stockport).—It is unlikely that the large Cypress trees will recover since so much of the foliage is dead. Certainly the means that our correspondent suggests (to defoliate the trees) are not likely to help them. The dead may be cut out and the living parts syringed frequently as the only chance of saving them. The trees were probably too large to move in the first place. Only when such trees are lifted with a very large mass of earth or transplanted practically every year before they are to be moved is there much chance of success.

TREES OR SHRUBS FOR CHALKY HILLSIDE (Enquirer).—The question of moisture for trees or shrubs during June and July arises in connexion with newly planted trees. They can grow from seeds because they have time to root deeply before they have much foliage to support. Japanese Cherries would be appropriate, but it would be desirable to dig the soil 2ft. deep if possible to give the trees a start. They cannot be reared from seeds, but small trees would be the most likely to take hold. Our native wild Cherry (*Prunus Avium*) and the double variety (P. A. flore pleno) should not be overlooked. The White Beam Tree (*Pyrus Aria*) would be effective in spring when in bloom, all the season when in leaf, and in autumn when the fruits change to orange. A quantity of St. John's Wort (*Hypericum calycinum*) planted near the foot would climb up the hill and cover the ground as few other plants would. It succeeds well on chalk in sun or shade.

ROSE GARDEN.

ROSES ATTACKED (A. M. T., West Calder).—The shoots of the Roses have been attacked by the Rose tortrix caterpillars, which have fed on the buds. None is present now, but probably they were of one of the common species. If only a few Roses are concerned, pressure of the attacked buds between finger and thumb is the most satisfactory method of dealing with them. There is also present the empty shell of a green fly that had been parasitised by one of the green fly ichneumonids,

showing that an earlier attack of green fly had occurred, for which the best treatment is spraying with a nicotine wash made by dissolving 3ozs. of nicotine and 4lb. of soft soap in 40 gallons of water.

FRUIT UNDER GLASS.

NECTARINE FRUITS CRACKING (J. R., Colwall).—In the absence of specimens we can only state that in our own experience of Nectarines in unheated houses too wide a variation in temperature from midday to midnight, accompanied by syringing the trees with water at too low a temperature, invariably result in spotting and cracking of the fruit. Moreover, moisture condensing on the fruit is apt to chill the epidermis, so that a few of the surface cells may die and turn brown, and then as growth and swelling of the fruit continues splitting or growth cracks may follow.

FRUIT GARDEN.

PEAR FOR IDENTIFICATION (B. S., S.W.18).—The Pear sent is probably Summer Beurre d'Arenberg, but the fruits were not sufficiently matured to say with certainty. This Pear should be picked when just ripe, as can be easily tested by lifting the fruit gently and if it falls into the hand with little leverage and without pulling it is ready. The actual time varies in different localities.

APPLE COX'S DRANGE PIPPIN UNSATISFACTORY (C. J. L., Braughing).—These leaves were from a "Cox's" nine or ten years old grown as an espalier. Our correspondent gives us no account of cultural operations, i.e., tillage or manuring, two important considerations. The leaves are mottled yellow and pale green, with the edges slightly browned, symptoms classed together as leaf scorch. Such scorching may be caused by faulty or unhealthy root conditions or by excessive heat affecting the leaves. Where due to root conditions the soil may be low in organic matter content, deficient in available potash and phosphates or lacking in lime. If the tree concerned is grown against a wall, scorching may be largely due to high temperature, with lack of sufficient organic matter in the soil as a predisposing cause. If our correspondent would inform us of his system of manuring and give particulars as to soil, etc., we might probably be able to give more detailed advice.

MISCELLANEOUS.

LAWN MOWINGS, CUTTINGS, ETC. (J. W.).—The leaf mould would have to be sifted for seed sowing and for cuttings and that would remove the lawn mowings, which would be injurious to seedlings and also to pot plants if used in quantity. Lawn mowings would stick together in masses, rot, hold too much moisture, keep air from getting to tender young roots, and so destroy them. Leaf mould should not be sifted for potting or planting, but the lawn mowings should be cleared away as well as possible to get clean leaf mould. Cuttings of Syringa (Lilac), Philadelphus and Forsythia can be inserted in pots of sandy soil now and kept close till rooted in a cold frame. They would root more quickly if placed in a close, moist pit or house with bottom heat. Plum-bago will root best in spring in a propagating or close case. Cuttings of young shoots, 3ins. long, with a heel are best. Cuttings of *Prunus triloba* and all the rest, except Plum-bago, can be inserted in a cold frame after the leaves drop in autumn. Any or all of them can be layered at the present time. Cuttings for pots should be 5ins. long, for the cold frame in autumn 9ins., inserting them 5ins. or 6ins. deep. *Ceanothus azureus* and *C. Gloire de Versailles* would be the most likely to succeed in Yorkshire, if trained to a wall facing south. The shoots of Plum-bago can be pruned back half their length now, and in October shortened to 1in. The old stems should not be cut back, but some of them may be cut away in October if too numerous for the space. A book that deals thoroughly with the propagation of shrubs is "Trees and Shrubs for English Gardens." This book is published at this office and a prospectus will be sent to our correspondent if he will kindly forward his name and address.

NAMES OF PLANTS.—J. W.—1, *Lilium pardalinum*; 2, Probably *L. Martagon* (specimen very poor); 3, *Sedum spurius* and var. album; 4, *Alechemilla alpina*; 5, *Veronica Traversii*; 6, *Fuchsia* sp. probably *flava* (specimen poor); 7, *Hypericum Androsænum*; 8, *Arundinaria Fortunei*; 9, Probably *Daxalina* sp. (specimen too scrawpy); 10, *Fuchsia gracilis*.—E. M. H.—*Rhus Cotinus*.—T. B.—1, *Chrysanthemum Parthenium*; 2, *Stachys Betonica*; 3, *Funaria officinalis*; 3, *Prunella vulgaris*; 5, *Lycynis divica*; 6, *Hypericum perforatum*; 9, *Lotus corniculatus*; 10, *Cereus luteotubus*; 11, *Valeriana officinalis*; 12, *Betaeum* sp. (specimen too poor for correct identification).—B. B. F.—Shoots of *Pinus major*.—Hereford.—*Berberis Carnation*: 1, The Ride; 2, Raby Castle; 3, Banner.—C. F., Ascot.—1, Rose Dorothy Perkins; 2, *Glearia Hauska*.—L. St. J. M.—*Spiraea Menziesii*.—Mrs. K., Oldstock.—1, *Salvia petens*; 2, Probably *Embothrium coccineum*.—R. C. W., New Eltham.—1, *Lycynis coronaria* Walker; *Trachymene* (cruella, a native of Australia (blue flower).

"WINDOLITE"

SUPERSEDES GLASS FOR ALL OUTDOOR STRUCTURES

"Windolite" is so much stronger, lighter and handier than glass that, once tried, it will be adopted by all Gardeners. Plants thrive under "Windolite," which not only does away with the old-fashioned, clumsy and fragile lights in frames, but can also be used on the lightest of framework for the protection of seedlings, fruit flowers, rock gardens, etc., where glass would be too heavy and brittle.

Consisting of a transparent composition reinforced with metal wire, "Windolite" is flexible and durable, and withstands all weather conditions. Keeping out cold, wet and draughts. Easily cut with scissors in any direction, it is easily fixed in position without putty.

Besides making practically unbreakable frames, hand lights, cloches, etc., "Windolite" is also largely used for POULTRY and all OUTHOUSES, for windows in FACTORIES, WORKSHOPS and SCHOOLS, for VERANDAHs, SKYLIGHTS, and many other purposes.

Many uses for "Windolite" are demonstrated at our Showrooms, where we are always glad to see callers.

Wherever Glass gets broken use "WINDOLITE."

If your local dealer does not stock, we will send an length from 1 yard upwards, carriage paid, on receipt of remittance.

EARLY AUTUMN FLOWERS

EVERY practical gardener knows that it is far from easy to keep flower borders interesting in early autumn. One by one the summer flowering plants become desolate until, in early September, few hardy flowers remain. A few second spikes of Delphinium, masses of the starchy Aster acris, and the ever-flowering Nepeta Mussini will provide welcome blue shades, and the later perennial Sunflowers and Solidagos will afford abundance of fairly showy yellow, but for the main colour masses, reliance must be placed upon Dahlias, Gladioli and Early-flowering Chrysanthemums. In all three families yellow and apricot tones are obtainable, also shades of pinkish mauve. Rich crimsons and salmon pinks are common to Gladiolus and Dahlia, and ruddy bronze shades are found in the early Chrysanthemum. For smoky tints of mauve and heliotrope we must rely upon the Gladiolus; indeed this flower displays them better even than the Carnation.

Since so much reliance must be placed upon these three families of plants, it is wise, if time permit, to visit nurseries and private gardens in search of suitable colour combinations. It will be found that in the Dahlia, soft art shades are especially prevalent in the Pæony classes, while brighter colour should be sought in the Decorative, Pompon, Single and Star groups. Almost all shades may be found among the Cactus sorts, but these do not, as a rule, make such effective splashes of colour in the border as do the other groups mentioned. A good primrose yellow Pæony-flowered variety is Nadia, admirable in colour and appearance for associating with crimson and purple tones in other flowers. For a charming shade of blush pink, Lillie is perhaps the best. Other good ones include Cassandra, orange-buff; Dream, a pleasing salmon shade; Ethel May, bronzy yellow; Gladys, salmon-buff; Jenny, soft rose; Polar Star, white, and Progress, salmon, fine erect habit. Richer colours are also to be found in this section, such as Gipsy Queen, dark crimson; Salome, bright orange; Luna, deep yellow; Sparkler and Martial, almost scarlet; Toreador, bright crimson, and Maggie, salmon rose flushed orange.

Star Dahlias are preferable to the exhibition singles for the mixed border and every one of Messrs. Cheal's varieties in this class is worthy of a place. White Star should certainly be included and of the others, personal taste inclines to Coral Star, Field Star, Yellow Star, Crimson Star, Reigate Star and the older but very desirable Crawley Star.

The great advantage of Dahlias is the length of their flowering season. They may always be relied upon to remain in full blossom until the first

sharp night frost. The Gladiolus, on the other hand, is short lived. By planting at a suitable season, however, its effect may be obtained just when it is most wanted and it has the grace and dignity so common among bulbous plants. The finish and texture of the flowers, too, are really beautiful.

Even a decade ago Gladioli were divided into numerous classes. Groff's, Kelway's, Childsii, Lemoinei, nanceianus, etc., but the ever increasing popularity of the exquisite primulinus hybrids has practically divided them nowadays into two classes, the primulinus hybrids and the large-flowered sorts. The Americans, always to the fore front with this stately flower, have lately evolved a large-flowered crimped or ruffled strain which will in all probability be worth placing in a class by itself.

Of the primulinus hybrids with their fine stems and generally refined colouring, the main thing, so it seems to the writer, is to avoid the sorts which are little more than miniatures—some of them hardly that—of the large-flowered type. The characteristic hooded form ought certainly to be preserved.

Following are a few first-rate varieties, but there are others which would make equal or greater appeal to many tastes. Myra may be described as giving an effect of rather salmony apple-blossom. Scarletta is one of the most brilliantly coloured, the total effect approaching to scarlet. Among yellows, Messrs. Kelway's claim for Golden Girl, that it is the nearest to rich yellow, should probably be conceded. It approaches that colour from the same angle as Lady Hillingdon Rose; that is to say, there is a distinct hint of buff in the coloration. Other fine yellows of paler tint but clearer colouring are Gold and Butter Boy, the latter easily identified by three brown streaks on the lip. Nydia, with its "darynaid" colouring of pink and white; Woodcote, nearly scarlet; Insurpassable, unhappily named, but a glorious orange buff; Enon, of orange apricot hue; Eurydice, an excellent pink; and White Buttercup, are all excellent. Some of the 1922 novelties are indescribably lovely

THE GRACEFUL GLADIOLUS PRIMULINUS NYDIA.
A beautiful variety of pink and white colouring.

DAHLIA 'FIELD STAR' AT MUNSTEAD WOOD.

CHRYSANTHEMUMS IN THE EARLY AUTUMN BORDER.

but will, for a while, be too scarce and dear for extensive planting.

Of the large-flowered type the number of varieties is quite bewildering, but for border decoration such cheap but effective kinds as Halley, Baron J. Hulot, America, Faust, Golden West, Empress of India, Lily Lehmann, Panama, Peace, Princes, Swahn, Yellow Hammer, Maréchal Foch, will amply suffice. They will be found with colour descriptions in any decent bulb list.

The ruffled varieties emanating from that eminent American raiser Kunderd are remarkable for the vigour of the plant and the beauty of the "grass," as well as for the characteristic ruffling or crinkling of the petal edges. Those anxious to try this new and very beautiful class should procure a couple or two of Alton, which in addition to beauty of form, has extraordinary beauty of colouring. The exact shade is hard to describe, but may best be described as a blend of clear but rather pale salmon and cerise.

With Early-flowering Chrysanthemums it is necessary to select varieties sufficiently early for the special purpose.

There is a great preponderance of yellow shades among the really early-flowering sorts. Of clear yellows the following are all recommendable. Mrs. A. Thomson, richest golden yellow, very free and bushy, 2ft.; Carrie, perhaps the best early yellow, but not so bushy as Thomson, 2ft.; Flora, an admirable pompon variety, also bushy, 2ft.; Champ d'Or, deep canary, spreading habit, 1½ft.; Clara, 2ft.; Ethel, a primrose coloured sport from Robbie Burns, 3ft. or more; and Horace Martin, the buttercup-yellow Masse, 3ft.

In bronzy shades there is a fairly wide selection as the following list shews:—Orange Pet, a large-flowered Pompon of graceful habit, with bronzy-orange flowers, 2½ft.; Bronze Pet, cactus petalled, bright bronze, 1½ft.; Harrie, orange bronze, rather large flower, 2ft.; J. Bannister, reddish copper on lemon yellow ground, rather thin and slender in habit, a sport from Perle Chatillonnaise, 3ft.; Mrs. E. Stacey, a pretty and compact growing bronze Pompon, 1½ft.; and Nina Blick, large and shapely rich bronze flowers, one of the most handsome, but not so early to flower as most of those mentioned, 2½ft.

Of pinkish sorts, the following are the most useful:—Gustav Grunerwald, early and dwarf, 1½ft.; Mr. Selby, a very neat and dainty soft pink Pompon, 1½ft.; Normandie, pale blush pink, 2½ft.; Perle Chatillonnaise, peach pink and cream, a fine flower, but rather sparse in habit, 3ft.; Provence, rosy pink petals, tipped gold, 2ft.; Perle Rose, deep rose with of course the hint of blue always present in pink Chrysanthemums, a beautiful variety, but not out until mid-September, 2ft.; and Mme. Marie Masse, rosy mauve, prolific and useful; this and its sports, several of which are mentioned, are quite the hardiest border varieties in existence: should be left outdoors in winter and flower better the second season than the first; 3ft.

Of reddish shades there are Goacher's Crimson, rich velvety crimson with gold reverse, 2ft.; Fleuve Rouge, orange salmon, unique and telling colour and a good flower, September, 2ft.; Little Bob, small bright crimson Pompon, neat compact flower, September, 1ft.; Minnie Carpenter, terracotta colour, habit somewhat in the way of Mme. Marie Masse, 3ft.; and L'Argentillais, bright scarlet crimson and gold.

Good white varieties are not numerous, but these include Market White, an excellent sort, 2ft.; Holmes' White, not quite so pure a white, but valuable as a dwarf variety, 1½ft.; and Roi des Blancs, with admirable flowers, but sparse of habit so should be planted rather thickly, 2½ft.

BULB ORDERS.—I

The Value of "Tips"—Crocus species, Hyacinths, Freesias, Lachenalias, Daffodils.

THE Horticultural Club has never been the same to me since it left the small, rather dingy room at the end of the long ground-floor passage at the Hotel Windsor. Its size and homeliness encouraged confidences. Within its walls cats not only looked at kings, they spoke to them and with them. It was here that Mr. William Marshall, who was for many years the chairman of the Floral Committee of the Royal Horticultural Society, once confessed to me that he did not know the early Tulip, Prince of Austria. If it had been some out-of-the-way variety like Karel de Moor I would not have been surprised; but, Prince of Austria!

In a similar way, one of the best and most knowledgeable gardeners in old Ireland confessed in a letter only a very short time since that

the bud stage), and Tommasinianus (with delicate looking flowers usually of a pale lavender colour and with the tube long and slender). As this last named species seeds freely and is very unstable in its colouring, a good deal of quiet and interesting amusement can be got out of raising seedlings, possibly, too, a little profit if anything of exceptional merit should turn up. I have, for example, a very lovely dark purple form which I raised from my own seed and which I am trying to grow into a stock in the hope that some day it may find itself "on the market."

I have an idea that one cause of the mild Hyacinth mania in Holland in the thirties of the eighteenth century was the development of the double flower. It seems to have gone on increasing in favour until somewhere about the middle of

apricot colour, but also because it featured the graceful Roman Hyacinth in its slender spike and in the loose arrangement of its small bells. Most of our leading bulb merchants now give it a place in their lists. It is not, however, a very sociable plant as far as its own family is concerned. One must see it alone to see it at its best. One then realises why it is yearly increasing in favour. It should never be planted singly, but three bulbs should be put in a 6in. pot and so on in proportion.

I wonder if anyone is thinking of taking the advice I gave not long since when writing about Freesias and is going in for seedling raising. The seed should now be sown. It is not too late to purchase bulbs (strictly one should write corns), but no time must be lost. Following my usual custom I am growing a collection of yellows. I have got some from Mr. van Tubergen of Haarlem and some from Mr. G. H. Dalrymple of Bartley. These will be grown alongside my own seedlings and the whole will provide interest and excitement when their flowering time comes round. Dainty, Merry Widow, Conquest, Buttercup, Rosebud and Canary are all good varieties with which anyone going in for coloured forms may make a start. Early to bed is the Freesia slogau, so buy and pot betimes. The sooner the better. My Lachenalias have taken a leaf out of Dizzy's book and after giving a really top-hole show, said before they went into their summer torpor, "The time will come when everyone will grow us." In early July I sent three little parcels to Australia and New Zealand, and since then I have sent some to Guernsey and the South of England. Perhaps the tide has turned. Considering the ease with which Lachenalias may be grown and their time of flowering, added to their wonderful lasting power, it is surprising they are not more often seen. A dozen Lachenalia Nelsoni, enough to make a couple of 5in. pots, would be sufficient for a trial test. Fashion is a fickle jade. You never know. It may be with Lachenalias as it has been with the Daffodil Cervantes. In the returns made by the Narcissus Committee in 1913, only a single member returned this variety as suitable for growing in pots. Now it has suddenly sprung into fame and bids fair to be a serious rival to all the yellow trumpets. It is so wonderfully free flowering. Messrs. J. R. Pearson and Sons in their 1922 list quote two instances of this from bulbs supplied to customers: in one case twelve bulbs of Cervantes produced forty-nine blooms, and in the other one bulb produced six. I have Mr. "Daffodil" Pearson's return of 1913 before me as I write; I fancy were he to fill the same form up in 1922 Cervantes would not be left out. No Daffodil can beat Henry Irving for early work in pots, especially if the bulbs have been grown in the region round about Penzance, or in Scilly, or in the Channel Islands. In the return above mentioned it came second to Golden Spur in the yellow trumpet section. Any Daffodil or Polyanthus Narcissus which is intended for early work cannot be potted too soon. Cervantes reminds me of old Hartland of Cork, because I believe that he introduced it into commerce. I think he told me it was the Italian form of Princess. The name of Hartland I always associate with the delightful Leedsu Countess of Southesk. No Daffodil has a higher decorative value as a cut flower. I am delighted to see it included in Pearson's list. I will conclude these notes with their description—"Countess of Southesk (Hartland). A very pretty bulb, especially valuable for cutting. A large starry flower, very much in the style of Frank Miles. Segments white, cup pale lemon yellow turning white with age. A very strong plant, flower stalks 18 to 20 inches long." Now comes the nasty part; price, half a guinea a dozen, Why not buy a few and grow your own stock?

JOSEPH JACOB.

A BEAUTIFUL CROCUS SPECIES, C. SIEBERI.

until this summer he had not known that exquisite, if somewhat fickle, annual *Phacelia campanulata*!

The moral is two fold. It proclaims the necessity for tips at bulb-catalogue time and, further, it tells us that the knowledge of the best ordinary varieties is not as universal as, in all probability, we imagined.

Thus, to take the Crocus family, we find some of the Dutch varieties in almost every catalogue and in every garden, but we comparatively seldom come across any Crocus species in the beds and borders of our friends. The time for planting the autumn-flowering ones is over, so I omit them, and only mention four of those which are to be found under the head of winter or spring flowering varieties. Every one ought to have a few of each, for they are quite hardy and they are among the first flowers of the new year to come into bloom. The quartet is composed of Imperati (when fully open a beautiful blend of some shade of purple and buff), Sieberi (a rather dwarf grower, with comparatively small flowers of a rosy lavender shade), Susianus or Cloth of Gold (another dwarf growing, small flowered species with pretty pointed blooms marked externally with rich brown stripes, which are most conspicuous when the flower is in

last century, when the tide turned and the single flower began to come more and more to the front. At the present time some of our leading firms do not catalogue a single double variety. All the same, anyone who can get hold of a few bulbs of the double pale rose Kastanbloom (Chestnut-flower) will find he has a very beautiful flower and like myself, will wish to grow it a second time. While on the subject of Hyacinths I can well remember the time when the graceful, small flowered Orange Boxen was cold-shouldered by the growers of Haarlem, and how at the dinner of the Horticultural Club after the first forced bulb show at Vincent Square, dear ancient (he was more than old) Mr. G. H. van Waveren took a spike, which I suddenly produced in the course of my lecture, out of my hand and dashed it down on the table, accompanying his action with such scornful vituperations in his own language that I never ventured to ask for a translation. You know the old saying about the blood of martyrs being the seed of the church. The death of my poor little spike seems to have given renewed life to the outcast. Hard headed and gallant hearted Mr. William Cuthbertson spoke up for it, and said he was sure the ladies would like it, not only because of its pretty and

SOME BETTER SWEET PEAS

All Sweet Peas are good. There are, however, some better than others and it is of these that mention is made here. Which are the "best," no one man can say for all; the popular heading the "Best Sweet Peas" is therefore shirked.

MY earliest recollections of Sweet Peas carry me back well over forty years, and the rows, some long, some short, in cottage gardens are still clearly imprinted in my memory. The plants are grown closely together, they are usually about 4½ ft. in height and they are always loaded with many coloured flowers whence comes a perfume unsurpassed by that of any other plant grown. Big posies are taken into the room and one inhales, eye tastes, the exquisite fragrance. One cannot do that with the sorts we grow to-day. That is one of the things for which evolution must answer.

Later they still come sharply to my mind in widely different circumstances and conditions. Now there are no rows of mixed colours, but instead long rows of plants more than 1 ft. taller, divided into sections of separate varieties, as profuse in their flowering and as delicious in their characteristic scent. The individual blossoms are larger, they are possessed of greater substance and if there be loss of scent, it is imperceptible. No one can take exception to what the process of evolution has done up to this point.

The third era in my little history may be said to have commenced with the celebration of the bicentenary of the introduction of the plant into this country. Paxton's monumental glass house, the Crystal Palace, was the venue of the most important shows in those days and therein the Sweet Peas were displayed. Scores of bunches, hundreds of bunches, thousands of bunches, more or less artistically arranged, and their perfume converted the normal atmosphere of the huge building, which was on the somewhat unpleasant side, to something indescribably clean and countrified and sweet—Rimmel's shop, if you will, but infinitely more delicious. Still the advance of evolution was in a direction at which none could call.

Next came the formation of the National Sweet Pea Society, which maintained its initial success by leaping forward in giant strides to the position next to that of our national flower, the Rose. Interest in the simple annual assumed a different aspect. From being an indispensable plant for the garden of the cottage, the villa and the hall, it became an exhibition plant and special shows in its honour were held all over the country as well as in our Colonies, while the village flower show without classes for Sweet Peas was regarded as generations behind the times. Enthusiasts, some with knowledge and many without, commenced selecting and cross-fertilising and novelties were pressed forward from all directions until the chaos of the varieties was exceeded only by the chaos of multiplied names. The result was, perhaps, inevitable, but it was to be deplored by those who were unwaveringly loyal to Sweet Peas which had a reliable character.

Concurrently ran the introduction of the waved flower, of which Countess Spencer must be recognised as the type. It was just about as splendid a beauty as it was a worry, for the simple reason that when seeds of Countess Spencer were sown no one knew what the harvest of flowers would bring forth. Actually it gave us many grand Sweet Peas, vigorous of constitution, profuse of flowering, but markedly deficient of characteristic fragrance.

WELL FURNISHED CLUMPS OF SWEET PEAS, 11 FT. HIGH.

Since then, although some varieties are more highly and pleasingly perfumed than are others, we have been constantly descending in what ought to be accepted as an essential attribute. The superb exhibitions of the National Society at the Royal Horticultural Hall failed to pervade the atmosphere with the same delicious scent that the flowers at the bicentenary celebration had done the atmosphere of the Crystal Palace.

And all the time the craze, for size was developing. Stems had to be 2 ft. long, individual flowers had to be a quarter of that length (more or less) across and if they were set oins, asunder on the stalks so much the better considered the exhibitors, and presumably the judges too, since it was the monsters alone which were accorded the places of honour. The National Society fought the tendency vigorously and received

unstinted support from those growers who were firm in their opinion that refinement should come first. The Society's judges upheld the perfect stem with its perfectly arranged blossoms and condemned by default the travesties of what a Sweet Pea should be. In the end the London exhibitions became collections of superb Sweet Peas, but the faults continued to prevail in many directions in the provinces. Now there are not lacking indications that size, with ungainliness, is again coming into the ascendant and it is a fact that all true lovers will not only deprecate most strongly, but will also fight against when they are called upon to act the part of adjudicators. Judges should never overlook the fact that they are teachers of what is best and exercise the utmost care that their judgments are educating the learners on the correct lines. But let me see to my varieties before the patience of reader and editor alike has gone.

It is not my intention to pass under criticism all the novelties of very recent years, because I have not had them in my garden and am not therefore qualified to express an opinion of value. It is true that several have been given a place once and either because of their similarity or inferiority to older sorts they have not appeared again. Some have come to stay, while others will have to wait at least another season, and possibly two, before final judgment is reached. It must be understood clearly, too, that the names do not constitute a special selection, but are simply of varieties of substantial excellence which may be relied upon to give satisfaction provided that their colours meet the tastes of other amateur growers.

As a pink there is none that appeals to me so strongly as Hawmark Pink, because it is charming from the moment of expansion to collapse; it ranks among the finest of all Sweet Peas in my estimation. As a white, Edna May Improved is a chaste beauty, but Constance Hinton is no whit inferior for those who do not object to the slight tint. Picture, among the cream pinks of deep shade, stands nearly alone, as does Mrs. Arnold Hitchcock among those of paler hue. Felton's Cream and Dobbie's Cream force me to act the pendulum in swinging from side to side, trying to decide which I prefer. Charity, as a crimson, seems to me to be unrivalled, in fact it undoubtedly is so compared with several others which have had their trials from time to time.

John Ingman and Mrs. Hardcastle Sykes are veterans among Sweet Peas, but neither has a rival in its own shade of colour. As dark and light blues respectively, Commander Godsall and Mrs. Tom Jones are well able to hold their own up to now in my esteem. No collection must be completed without a lavender and as a pure shade it will not be easy to find a superior to R. F. Felton. Maroon, either reddish or chocolate, does not make strong appeal to me, but I am willing to pay tribute to the merits of Splendour and Warrior. Royal Purple stands alone, so no more need be said of it. In picotee edged my favourites are Annie Ireland in the white ground set and Jean Ireland in the cream ground group. As a scarlet I incline to the view that Hawmark Scarlet is the best that has had a place in my garden, but must confess to some doubts on the point when I remember the glorious clumps of Dobbie's Scarlet which have been grown. Mascott's Helio in its peculiar shade of lilac, Mrs. J. T. Wakefield, flushed, and Magic, as a tawny, have always pleased me by their excellent qualities, though I am not always satisfied that their colours make strong appeal.

Tangerine, richest of orange; The President, glowing orange scarlet; Royal Salute, and Royal Scot, deep and scarlet cerise respectively; must have their places in exhibition collections as they are all of very conspicuous merit, but as I do not

exhibit and have a rooted objection to turning my garden into an apology for a drying ground I do not grow them because they burn and that

badly; however, each to his or her own taste as well in colours, and in sizes, shapes and "drying grounds." H. L.

WATER LILIES

ONE of the most fascinating and interesting phases of gardening, where there is a large enough expanse of water, whether pond, lake or rivulet, and pleasant surroundings, is the cultivation of aquatic plants in general and the hybrid Water Lilies (*Nymphæas*) in particular. It is remarkable with what rapidity these beautiful and interesting plants have of late years come to the front, so that there are few gardens of any note without their Water Lily tank or artificial pond.

Natural or artificial sheets of water dotted with these fragrant flowers and the accompanying fresh green or mottled leaves, are sights not readily to be forgotten. All are quite hardy. They range in colour from snow white to cream, from soft pink to dark crimson, and pale sulphur to full yellow, and their foliage seems specially designed to lend added beauty to each particular type and hue of flower. It is very desirable that *Nymphæas* should be planted in full sun, and in still water, though the stronger growing kinds, such as the *Marliacea* group, will thrive in slightly running water if planted in nooks or bays away from the full force of the current.

Whether planted in tubs, tanks or small ponds, evaporation takes place, but water for replenishment should never be allowed to enter with great force, or a large quantity at one time, as the sudden chill is harmful and especially detrimental to their flowering. Water Lilies are not at all capricious as to soil, but it should be rather on the stiff side. Stiffish loam mixed with a little well decayed cow manure is excellent

Planting may be proceeded with during May and June, but they may be safely transplanted as long as the water remains warm. When intended for large ponds it is better to plant first in baskets and sink in the required positions for flowering. When planting in tubs, these should be pitched inside and out and then sunk in the ground until the edge is but a little above the ground level. There should be 6ins. to 9ins. of prepared soil placed in the bottom and the roots should be firmly planted, leaving 9ins. to 12ins. of water all over.

It is always well to introduce gold fish into tubs and small artificial ponds, as they destroy the mosquito larvæ and other injurious water insects. If fed from one corner the fish become quite tame and are much in evidence towards feeding time.

The list of *Nymphæas* is a long one, so I will confine myself to a few of the better and more prolific sorts.

VARIETIES FOR 1FT. TO 2FT. OF WATER.—*Marliacea albida*, large flowers, white; *M. carnea*, bluish pink; *M. rosea*, rich rose; *M. rubra punctata*, rich purplish red, spotted carmine, has conspicuous orange scarlet stamens; *M. chromatella*, a real gem, having large sweetly scented chrome yellow flowers, should be in all collections; *Colascea*, rich rose, very free and vigorous; *Escarboucle*, a most beautiful vermilion flower; *Robinsoni*, medium sized flowers, a pretty crimson vermilion, shaded towards centre with rich ochre foliage, spotted chestnut brown; *Moorei*, this is undoubtedly one of the finest introductions, large globular shaped flowers of a beautiful soft yellow, with dark olive green foliage, marbled chocolate; *Mrs. Richmond*,

another exceedingly handsome variety with clear soft pink flowers, very vigorous; *Gladstoniana*, one of the best for large ponds, having large ornamental leaves and gigantic snow white flowers.

FOR TUBS OR TANKS FOR 6INS. TO 9INS. OF WATER.—*Laydekeri fulgens*, rich amaranth; *L. purpurata*, rose, shaded lilac; *odorata minor*, small pure white flowers, very suitable for aquaria; *o. Exquisite*, clear pink; *o. sulphurea*, large flowers of clear sulphur shade.

Other attractions to the water garden are the many varieties of bog and water plants for planting near the edge of the water, or forming small islands; these, however, are best planted earlier in the year.

W. LOGAN.

BULBS FOR THE ROCK GARDEN

THERE lives a man who, not so very long ago, said that he would have no bulbs in his rock garden. The flowers were all very well, many of them quite good in fact, but there was the "afterwards" to be faced and he drew an awful picture of fading stems and dying leaves just when everything else was at its best. Of course, his rock garden—to use his own phrase—was "quite good"; there is such an abundant mass of non-bulbous material that it could hardly be otherwise, so that he cherished his delusion until one day, early in April, he visited my garden, when a sudden and very violent conversion took place. If this was what bulbs did for the alpine garden—well! I could not refrain from reminding him of the gigantic masses of decaying leaves that must, so he had suggested, mar the scene in May and June, but I invited him to come again and advised him to visit Kew and see the bulbs there. He almost fell down and worshipped before a little clump of *Narcissus triandrus* (Angels' Tears), and left, a badly shaken man. Later I heard that he had been to Kew and that this had completed the cure. His own bulbless garden became unsatisfactory in his eyes and he impatiently awaited planting time so that he could rectify the omission. When he came again I took him to the rock garden to prove that the barren masses of decaying leaves were not there.

No doubt there are others, like my friend, whose gardens are lacking just what his lacked. They thus miss some of the real charm of new-born spring. For the amount of fading foliage that obtrudes itself depends upon the planter and the means that are taken to associate the bulbs with other plants and thus screen them when the inevitable dying back does take place, while the pictures which a free use of dwarf bulbs enables us to create are abundant repayment for the thought and time involved. Consideration must be given to date of flowering, height, colour and suitability in connexion with the plants immediately surrounding them, and, finally, aspect, from the point of view of the plants themselves.

All dwarf and early-flowering bulbs, such as the tiny *Daffodils*, should have an "open" carpeting plant through which they can easily make their way. Many *Dianthus*es are excellent for this, as the growths permit the tiny bulbs to spear their way through and yet keep the flowers from becoming mud-splashed in showery weather. Mossy *Saxifrage*s are often recommended for this purpose and very good they are too, but I prefer something that enables the growth to make its way through more readily. Where used thus, choose one of the green-foliaged *Dianthus*es rather than a glaucous-leaved kind; the latter does not give sufficient contrast and detracts from the faintness of the flowers.

WATER LILIES AT GRAVETYE MANOR.

One could scarcely have too many of these miniature Narcissi—*cyclamineus*, *juncifolius*, *trifidus*, *Bulbocodium*, etc., for, wherever they peep out, they are indescribably attractive and, once established, do better and better with each year that passes. Many people are disappointed with these the first year after planting, because flowering is sparse and the majority of the bulbs only produce leaves, but time alone will correct this. Give them a position where they will be partially shaded during the hottest part of the day; plant about 1½ ins. to 2 ins. deep in a rich loam and time will do the rest.

An especially attractive plant is *Romulea Bulbocodium*, that resembles but is harder than *R. Celsii*. A great sun lover, it requires a light sandy soil, nestling against the foot of a large boulder that first absorbs and then gives out the heat of the sun. *Scillas* are very "alpine" and both early and late, give a splendid selection of dainty little flowers, rich in real gorgeous blue, a colour that illuminates and penetrates in its vivid intensity. *S.S. bifolia*, *italica*, *unifolia*, *verna* and *sibirica*, all are grand species for the rock garden and, if an especially "cunning" little effect is wanted, try planting these close to a group of *Saxifraga cordifolia* (*Megasea*), so that the lovely little flowers are seen against the large glossy, rather coppery leaves of the *Saxifrage*.

After mid-April we can enjoy a continuous procession of Tulips, in every gorgeous hue that this wonderful genus contains. Not the common border or bedding Tulips, of course—these would be out of place—but the wildling un-improved children of Nature, little gems only a few inches high but glowing with a fire and brilliance that compete on equal terms with the finest of the florists' varieties. A rock garden rich in these is an enviable place indeed during the best of the spring days, for there you will have Tulips that flame in gold and crimson, blush in softest pink or cream or white, endeavour to prove that they are wee Water Lilies, or cajole us into the belief that they are star dust dropped from last night's sky. Tulips, in short, in such a diversity of form and colour that those who are only familiar with the garden forms would rub their eyes and stare in amazement.

Among the choicest little plants of all for shaded nooks, where the ground is cool, moist and rich in leaf mould, are the hardy *Cyclamens ibericum* and *repandum*. These look best in little colonies, with here and there an isolated plant breaking away from the main mass. *C. ibericum* is sometimes listed as *vernum* and is doubly beautiful, in that the leaves are nearly as attractive as the lovely little crimson flowers on thin stems which never exceed 3 ins. in height. There is an equally charming white variety of this with a crimson blotch at the base. The *repandum* varieties are slightly taller than *ibericum*, with ivy-like leaves, barred with a silver zone. These are later in flowering too, being at their best in April and May. By including a group of each species therefore, one has a continuous succession of wee flowers from early February to mid-May. When these plants strike a home that is to their liking, they lose no time in taking possession of it by sowing their seeds all round the original colony so that as the years pass they peep out far and wide, and are usually especially happy in their "choice" of positions. In company with these should be the *Hyssopus* (*Dog's Foot Violets*), ideal frail-looking, shade-loving plants that are, however, absolutely hardy. These plants are much more individualists than the *Cyclamen* and a single plant or quite small colony in just the right setting is one of the most beautiful sights that the rock garden can show. Do not omit an annual dressing of old manure and peat in equal mixture over the spot where they are growing. With this attention

they are long lived and flower splendidly every year. It is, perhaps, curious that, although they love damp, they detest wet and never do better than where growing in a rather loose soil, below which there is ample drainage.

The charms of the dainty little bulbous *Iris* must not be overlooked. These are gems indeed and fill many a little sunny nook as no other flower could do. There are *I.I. bucharica*, *caucasica*, *cristata* and *orchioides*, for instance, lost in the space of a mixed border, but plants of glorious charm amid rocks. *Iris orchioides* is one of my own particular favourites, with its self-coloured yellow flowers on foot tall stems. It is a delightful little plant, well worth the trouble of making happy, which is easily done if a sunny spot is found. The soil should be very light and sandy, but well enriched with rotten leaves and old manure. It should be disturbed as little as possible, for it has thick fleshy roots that remain attached to the bulbs during the resting season; time, therefore, is required to establish them. Of course *I. reticulata* must be planted, and planted freely too; there is nothing to excel this for early flowering. If the season is at all forward, mid-February will see the first of the lovely deep blue flowers, with a brilliant touch of deep orange on each fall, expand; these continue to open in succession for several weeks. The bulbs are covered with an outer coating of netted fibre and should not be planted too deeply. Another point that should not be overlooked in connexion with this is to plant in rather poor and stony soil. I speak feelingly, remembering one of my own mistakes. The bulbs came to me from a friend and I put them in a deep pocket, filled with a rich fibrous loam. The first year two flowers! "Oh," said I, "freshly planted of course—next year." And I watched the long strong leatage with a cheerful heart. But that is just where I made my mistake, strong leatage is not a sign of health and the following year I got no flowers. Then I did what I ought to have done earlier, consulted the donor of the bulbs. His plants, I found, did not make long leaves; on the contrary, they were quite

dwarf even in early July and the bulbs that flowered most profusely of all were those that had, in course of time, worked their way out into a gravel path. I took the hint, went home and changed the position of those bulbs at the earliest opportunity. Now they grow, but not over luxuriantly, and I have never since had a

A LITTLE COLONY OF NARCISSUS CYCLAMINEUS.

CROCUS SIEBERI, VAR. ATTICUS, IN THE ROCK GARDEN.

season pass without flowers. To me too, the Spring Star Flower, *Milla uniflora*, always has a special charm, while it is one of the most permanent of all bulbs. Once planted, it seems to go on for ever and there should be an increasing mass each spring of the lovely pure white starry flowers that last so long in perfection.

Fritillarias, Muscaris, Crocus species and others of that ilk should be used lavishly, but more in the approach to than in the actual rock garden itself, for they do so well among Ferns, shrubs or short grass, that they are more useful there than in the pockets among the choicer plants.

The above remark applies, of course, to the bulk of varieties among the genera named, but, and especially in the case of the Fritillarias, there are

a few varieties so good that nothing less than a dwelling of their own meets the case. There is, for example, *F. pudica*, an entirely distinct form with small drooping bell-shaped flowers, first green and later becoming golden yellow. One of the most magnificent of all is *F. recurva*, a splendid Californian species that must have a protected spot and a rich cool soil where it can produce its tall stems, carrying the chequered scarlet and yellow flowers.

To revert for a moment to the Muscari. Those fond of the quaintly beautiful should procure a dozen bulbs of *M. plumosum*, the Feather Hyacinth, the flowers of which have become little more than long twisted mauve threads, the whole forming a feather-like flower of striking appearance.

H. W. CANNING-WRIGHT.

THE HERBACEOUS PHLOXES

As the planting season is gradually drawing near, perhaps a few remarks on these beautiful summer and autumn flowering plants will not be inopportune.

ALTHOUGH herbaceous Phloxes will thrive, more or less, in the majority of soils, those who wish to excel with them should bear the following points in mind.

These Phloxes are gross feeders, so a well enriched soil that has been deeply cultivated should be chosen. During the period of growth copious supplies of liquid manure or other such stimulant should be given. In the event of a drought a good mulch of well decayed dung will materially assist in retaining moisture and supplying nourishment to the roots. The value of mulching under such circumstances was brought home to us last year at Mr. Jones' nursery. These mulchings enabled Mr. Jones to bring to the R.H.S. meetings at Westminster, despite the unfavourable season, many fine groups of Phloxes. Phloxes certainly show to greatest advantage planted in masses, preferably of one colour. If planted in beds it is advisable to have depressed surfaces so that rain will not run off. Phloxes are surface rooting plants so these depressed surfaces will also allow for a rich mulch. When planting the heights that various varieties attain should be taken into account.

The actual planting is best carried out in early autumn and this is practically essential on light soils. At this season the soil will be moist and warm, which will enable the plants to get a firm grip of the soil before winter sets in. The earlier the planting the finer is likely to be the display of bloom the following summer.

Plants from the open ground are undoubtedly best and yearlings raised from cuttings better, generally speaking, than divided stuff. There are many gardeners none the less who never propagate Phloxes from cuttings. They divide up large clumps during the autumn. This division often meets with a certain amount of success. However, rooted cuttings are far superior, as they have the merit of possessing a new lease of life, whereas the divided portion is more or less exhausted. Division, too, often produces poor, straggly plants and inferior blooms.

If one must rely upon the divided clump as a means of "propagation," only the outer portions should be planted and the centre be consigned to the rubbish heap. Now as regards stakes, it is advisable to put these in place as early as possible so that damage to the spreading roots may be minimised. The flower stems should not all be tied to one stake, otherwise the plant is but too likely to take on a besom-like appearance. Nor

is it advisable to use over long stakes for the purpose since this will sadly mar the picture when the plants come into flower.

A BORDER OF PHLOXES.

Each shoot should be spread out and attached to a stake. Where the shoots are numerous the weakest ones should be removed. The sooner this very necessary thinning can be done the greater will be the amount of vigour available for those selected to produce perfect blooms.

As cut flowers many varieties of Phlox look admirable. The spikes should be cut before the

flowers fully expand. Some varieties are especially charming under artificial light. They are, however, unsuited for table decorations because of the possibility of the pips shedding.

The list of varieties is now exceedingly long. The following list, while not in any way exhaustive, contains some of the best and most distinctive. Dr. Charcot, bluish mauve, has large flowers in good trusses; Elizabeth Campbell, light salmon, very large truss, is an old favourite; Frau A. Buchner is perhaps the best pure white; Embrazement is a fine salmon with darker eye; Dr. Königshofer is one of the best of the orange scarlets; Freifraulein von Lassberg, another good snow white sort; G. A. Strohlein is almost vermilion in colour with a carmine eye; H. J. Jones is quite the best of the rosy scarlets; Le Mahdi is probably the best violet blue, not an attractive colour to many people, nor are the pips a very wonderful size; Gen. van Heutsz is a salmon red, white centred, all sorts approaching this colour burn in strong sunshine. Gruppenkonigin, flesh colour, carmine eye; Mrs. H. Jenkins, white; William Watson, soft pink, mauve eye; Tapis Blanc and suffruticosus Snowdon, both good dwarf whites, are all excellent.

Besides these we have Mrs. J. H. Jones, mauve, shaded pink, carmine eye; Mrs. A. W. Alder, shell pink; Muriel Alder, salmon red, dark eye; the Rev. Gilbert Raynor, a fine intense salmon;

Rijnstroom, rose pink; Rosenberg, carmine violet, blood red eye; Mrs. Louie Williams, deep salmon; C. Edwards, clear salmon, bids fair to come to the front; La Neige, white, fine truss; Imperator, rich crimson; Jesse Waters, salmon orange, carmine eye; Florrie Freeman, carmine cerise, and Hanny Piledeker, ere my blush, carmine eye. G. H.

THE ENEMIES OF THE GREENFLY

THE greenfly has three inveterate enemies—the hover-fly, the lacewing-fly and the ladybird. With all of them, in their adult stage, we are familiar. The ladybird needs no introduction; the lacewing, with its large, delicate wings, its green body and its brilliant golden eyes, we have often seen resting on a wall or fence; and the black and yellow banded hoverflies are exceedingly common in every garden, especially towards the end of summer, poising over the flowers or darting to and fro like tiny hawks.

All three insects should be protected in every possible way, for their grubs all feed on aphides or greenfly; and they feed on them to such an enormous extent that they destroy far more than any remedy we can devise.

The eggs of both the lacewing and the ladybird are easily detected and, therefore, easily preserved from destruction; they are laid in groups, and the groups are sufficiently large readily to be seen. In the case of the hover-fly, however, it is different; one egg only is usually laid at a time and, of course it is so small as to be practically invisible. Three days after this minute, bolster-shaped egg is laid the grub hatches out; it is blind, light yellow in colour, less than one-sixteenth of an inch long, and ready from the moment of arrival to catch and eat greenfly. It does not actually eat them, by the way, it sucks them; but, so far as the gardener is concerned, the result is the same—the complete annihilation of the pest. The grub is provided with a curious three-spiked weapon

on its head, and with this it seizes and holds aloft its prey. When quite young it can manage only

THE LARVA OF THE LADYBIRD, POPULARLY CALLED "NIGGER."

two small greenflies per day, but before it reaches the pupation stage it devours one every minute! And this goes on all day, and probably most of the night. What insecticide can boast such a result? The colour of a full grown grub is a pale green, with a touch of reddish purple at the tail, and a whitish dorsal stripe. It is rather easy to overlook these greenish, slow-moving creatures and to brush them away with the greenfly.

Fortunately, one is not at all likely to overlook the black and red larva of the ladybird. The eggs are greenish in colour and are laid in little bundles; sometimes they are so yellow that it is possible to mistake them for the eggs of the Large White butterfly. As soon as they hatch out, however the larvæ are leaden grey, almost black, with patches of red; they are fairly active, hunting about on the leaves for their food and eating every greenfly they find. The chrysalis is a little dark, shapeless object that hangs, head downward, on the upper side of a leaf or on a twig. Both the insect and the larva have the power to exude a very disagreeable odour by means of a liquid that comes out of the joints of the legs; this odour is very perceptible if a number of the little beetles chance to hibernate during the winter in a living-room. But in spite of its disagreeableness, or perhaps because of it, this liquid is considered by some country-folk to be a good remedy for toothache.

I do not think the hover-fly, as an adult insect, is ever carnivorous. There is a doubt about the lacewing in this respect, because it seems to have the power to inflict a slight bite on the skin. About the ladybird there is no doubt at all; it is certainly carnivorous and a very good hunter; I have seen it exhaust and kill a gnat in a very few seconds by sucking its juices. Therefore ladybirds are useful in the garden, both as larvæ and as beetles.

As larvæ, perhaps the lacewings are the most voracious of these three insects; they are also merciless cannibals should the supply of greenfly fail them. For this reason, it is a wise provision of Providence for their race that the eggs are laid apart and each on its own little foot-stalk. Sometimes it does happen that the eggs have been laid quickly and that the stalks have, in a way, run together, so that the eggs appear as a little bunch, and in such a case the first larva to escape from its shell will probably eat all the other eggs, or the larvæ as they appear. But usually the stalks are quite separate, and each little newly hatched grub has to climb down its own stalk and go in search of greenfly. The way these eggs are laid is very remarkable. The lacewing first places on the leaf a drop of sticky, transparent fluid; she keeps her ovipositor attached to this and draws it out and up into a thread that hardens very rapidly; on the top of it she places her egg, probably fastening it to the thread by another

drop of the liquid. The eggs have a papery, vegetable appearance, and this led casual observers some years ago to conclude that they were some sort of moss or fungus. It is possible that this liquid, which hardens round the eggs into a sort of parchment, is disagreeable to birds; otherwise one wonders why the birds do not snap them all up.

The pupæ of the lacewings are not often seen, because the larvæ, before pupation, wander away and hide themselves in chinks and crevices and withered leaves. The fly emerges during the day, as the warmth of the sun is necessary to develop the wings, but for the rest of its life it is inactive during the day and flies at dusk.

Besides its stalked eggs, there is another strange feature in the lacewing's career, and this is the fact that the pupa, before the emergence of the perfect insect, develops leg-muscles that are functional. As soon as the fly is ready to appear, the pupa cuts its way out of the pupa case with

THE LACEWING-FLY.

CURIOSLY STALKED EGGS OF THE LACEWING-FLY.

a pair of specially constructed jaws that are used on this occasion only, and then climbs out and seeks a rough projecting surface. When it has found a suitable spot, usually a tree-trunk, it remains quiet till the skin splits on its back, and the small, crumpled wings appear; the pupal skin is now finally discarded, and the fly hangs on to the trunk till its wings have grown and stiffened.

There is very little one can do to induce these immensely useful little foes of the greenfly to breed in our gardens. Only in the case of the hover-flies are we able to place any attraction in their way. Hover-flies are all very fond of certain flowers, among which are Michaelmas Daisies and Mint blossoms. It is certain that, after enjoying the sweets of these flowers, the flies would be more likely to lay their eggs among greenfly near at hand than wander off elsewhere; so it would be a wise thing to see that the garden contains a flourishing bed of Michaelmas Daisies or Mint or any other flowers over which these flies are observed to hover and dart.

M. H. CRAWFORD.

HOVER-FLY PUPA.

CORRESPONDENCE

CENTAUREA CANDIDISSIMA IN SEASIDE GARDENS.

WERE I to name one plant as quite indispensable to seaside gardens, I should certainly say *Centaurea candidissima*. Tender it may be in inland and sheltered gardens, but plant it in the most exposed, windy spot on the sea coast, where the wind dries up all stagnant moisture, it proves itself the hardiest of the hardy. Need I say how very ornamental it is when properly planted? The other day I came across a tangled mass of the lovely soft rose-pink form of *Convolvulus althaeoides* in full flower, this *Centaurea* towering above it with its bold silver leafage and handsome yellow heads of flower, contrasting with the purple of the wild Knapweed, while the whole hillside is overrun with *Muehlenbeckia complexa*, never so happy as by the seaside. No formal bedding could surpass the beauty of this semi-wild cliff side. The *Centaurea* grows into big rounded masses of foliage that neither wind nor rain nor cold seems to touch, taking care of itself in the most satisfactory manner. With a few *Fuchsia* bushes or the hardy *Olearia Haastii*, nothing more is wanted to enliven a cliff side garden where *Thrift* is already in evidence and with the pretty little white or pink *Convolvulus arvensis* of the cliffs. Even the penurious Folkestone gardeners might take a hint? Their cliffs *do* need beautifying.—E. H. W.

SEMPERVIVUMS ON NAKED ROCK.

I ENCLOSE a photograph, which may be of interest to your readers, of a rock planted with *Sempervivums*. These plants are usually rather uninteresting in a rock garden, but when planted on a rock give an added charm, especially with the numerous kinds that are now procurable and if, in selecting and planting, the colours are considered. The limestone rock was first planted

SEMPERVIVUMS FLOURISHING WITHOUT SOIL.

with *Sempervivum arachnoideum* about 1913 and larger varieties added later. The rough surface of rock was covered with powdered limestone and earth mixed so as to form a kind of mortar and *S. arachnoideum* gently pressed into it. This mortar dries quickly and does not crack. It holds the plant in place till it is rooted, by which time the weather has gradually removed the mortar. For the larger kinds a steel drill was used, and holes bored 2ins. or 3ins. deep and roots packed into these with earth and finished off with mortar. *Saxifraga Sir Francis Cade* can also be grown like this. Its rosettes may be seen towards the top left-hand side of the rock in the illustration. At the base can be seen the white flower of *Saxifraga lingulata lantoscana superba* and *S. Aizoon rosea* spikes about to flower, also rosettes of *S. Sir Francis Cade*. At the bottom left-hand corner can be seen *Wahlenbergia serphyllifolia major* about to burst into flower. There are eight varieties of *Sempervivums* now growing on this rock, and last year *Sempervivum arachnoideum* had eight or nine flowers.—H. P. LESCHALLAS.

YUCCA FILAMENTOSA?

I ENCLOSE a photograph of a *Yucca* which I believe to be *Y. filamentosa*. It forms at present a very attractive object in my little front garden. The plant flowered for the first time two summers ago and then broke up into about a dozen crowns, four of which have sent up flower spikes this season. Is it advisable to divide the plant which will probably be overcrowded with new shoots later on and what is the best time for this operation?—G. S., Loughton, Essex.

[Both those very similar *Yuccas*, *Y.Y. filamentosa* and *flaccida* and their almost innumerable hybrids, may be increased by division. These species produce rhizomatous underground stems which will make good plants when cut off and potted. Division is best carried out fairly soon after flowering. Unless, however, our correspondent's clump shows failing vigour in the height and size of the flower stems, we should be inclined to leave it undisturbed. From the photograph the plant probably is *Y. filamentosa*.—Ed.]

PRUNING CLEMATISES.

FROM correspondence which has appeared from time to time in the horticultural press, there undoubtedly appears to be some confusion as to the correct treatment in pruning the various types of Clematis. I had a practical demonstration of the fact when visiting a private garden towards the end of the autumn. The owner was conducting me round, discussing the merits of various plants, when we came to a strong, healthy Clematis

covering a considerable wall space. He asked, "Can you tell me why I never get any blooms on this plant; it has been well manured and cut hard back every year?" I saw at once from the foliage that it was a spring-flowering variety of

A GOOD PLANT OF YUCCA FILAMENTOSA (?).

the *Azure* or *Patens* type, which flower from the old wood, so was able to assure him that if he would instruct his gardener not to prune it back hard that winter he would have a wealth of blossom the following spring.

All Clematises need some pruning, and this should be done in February or early in March, after the severe frosts are over, and the buds commence to show signs of swelling.

It is impossible to mention particular varieties where they are so numerous, but speaking generally, all spring-flowering varieties of the *Azure*, *Florida*, *Anemoniflora* and *Calycina* types, which flower from the old ripened wood, only require to have the weak, straggling or overcrowded branches removed. In the case of the rampant growing varieties, such as *C. montana*, it is a good plan to cut back hard some of the branches each year to encourage new growth from the base, and so prevent the plants from getting out of control and becoming bare and unsightly.

The large summer-flowering varieties of the *Lanuginosa* type are not so rampant as the autumn bloomers, so it is often only necessary to prune back the weak or dead branches to strong breaking eyes, though where they do well they may be cut back to within two pairs of axillary buds.

The large autumn-flowering varieties of the *Jackmanii* and *Viticella* types, which flower in profusion from the young summer shoots, require to be pruned back hard to within two pairs of axillary buds, to encourage the development of vigorous young shoots, while the small flowering

varieties of the *Viornæ*, *Wokingensis*, *Aromaticæ* and *Erectæ* types require the shoots cut back as far as they annually die down.—A. G. JACKMAN.

A "PALM" IN FLOWER.

I HAVE been greatly interested in the photograph and description of the flowering of a *Cordyline australis* in Kent, given by Colonel A. C. Borton in your issue of THE GARDEN for August 12. We have had a somewhat similar experience further north and it may interest you to learn that at Castlehill, Ayrshire, N.B., a *Cordyline australis* bloomed most luxuriantly this summer and at the same time the Palm, *Chamærops Fortunei* flowered freely. They are both in open ground and no special care is needed in winter. The flower spike of the *Cordyline*, when cut off, measured

Surely she must have misunderstood the genial and learned Prof. Chodat in saying "Only six hours from here (Bourg St. Pierre) by the post cart" to the Hospice. It is only eight miles by the road, and of course less on foot by crossing the zigzags. The traveller must indeed be congratulated on spotting from a carriage the tiny *Saxifraga cæsia* "in abundance at the sides of the road." Whenever I walked along that truly dismal road above Bourg I failed to see it, though this rare *Saxifraga* is frequent between here and Val Ferret. Getting out of the carriage she found, "near the river, *Gentiana germanica* of an ugly red mauve." This could not be *germanica* at that height and season, and was possibly a colour-form of *G. campestris*. *G. germanica* is a plant of the plains, hills and sub-alps, and is at its best in September and October.

when Savoy was ceded to France (1859), and that a good stretch of Italian Piedmont intervenes between the St. Bernard Pass and Savoy on the West.

What is meant by the statement that the Linnæa garden "contains 25,000 different plants"? Ten years ago there were about three thousand kinds of plants in this beautiful and half natural garden. It would be interesting to know about how many more species are there now. Yes, it is a "wonderful drive" and a still more wonderful walk down from the Hospice to Martigny; but the drop is not quite "8,000ft. in two hours" (by motor-car), but 6,560ft.—H. STUART THOMPSON.

THE RETURN OF THE EARWIG.

BE the season what it may, on the approach of autumn the earwig gives evidence of its presence in the garden. If in the borders there are to be found Anemones, Chrysanthemums, Dahlias and Sunflowers, so surely will this pest be present. You may have admired one evening the chaste white blossoms of *Anemone japonica alba*, rising from out a perfect setting of their dark green leaves, only to find on visiting the garden next morning that both blossoms and foliage have been subject in the short interval to numerous perforations such as to render them useless for cutting. The depredation among Dahlias is equally bad, and the most promising crown buds on the choicest Chrysanthemums fall a prey to this enemy of the gardener. As yet there does not appear to be any reliable specific for the prevention of the inroads of earwigs amongst plants which are peculiarly liable to its onslaughts. *Dahlia* growers of a former generation trapped the pests in inverted flower pots containing wool or moss. The same "dodge" holds good to-day. There is no easy way to the extermination of earwigs. The grower for show of both Dahlias and Chrysanthemums takes little or no risk. As with his forefathers, so with him, the nightly visit with lantern in hand and a pair of sharp scissors, is the only specific he believes in. It involves trouble, but it saves the best blooms, probably, and this is what really counts.—L. W.

IS THE HOLLYHOCK DECLINING?

IS the fungoid growth to which Hollyhocks are susceptible, and which makes its presence felt more particularly on old plants, by an early rusting away of the leaves, the reason why they are seen less frequently in gardens than they were thirty and more years ago? Possibly this may have had a deal to do with the decline of this one time popular florist's flower. The mistake made by those who used to grow Hollyhocks, and who have since given them up because of failure through the prevalence of fungus, seems to me was of treating them as perennials and allowing all and sundry suckers to remain, the result being that the original plant developed into a colony of plants, filching from the soil most of its nutriment very quickly and rendering the plants an easy prey to the rust disease. Hollyhocks, when well grown, are such noble and attractive plants for the back of a border, or for grouping, that it seems a pity their popularity should be on the wane. I think if we treated them more as biennials and gave them fresh quarters, in medium soil, rendered rich with rotted manure and decayed vegetable matter, we should hear less of disease. I feel confident that the biennial treatment of the Hollyhock is the only sure and safe method to overcome the dreaded fungus. Hollyhocks are best planted at the back of herbaceous borders since they lose their bottom leaves when attacked by this disease, which gives the plants a very untidy appearance when planted alone in beds.—C. ARENOR.

CORDYLINE AUSTRALIS IN FLOWER ON THE RIGHT. ON THE LEFT CHAMÆROPS FORTUNEI, ALSO IN BLOSSOM.

7ft. in height and 8ft. in circumference, the tree itself being 16ft. in height. I enclose a photograph shewing both plants.—(Mrs.) HELEN J. WILSON.

THE GREAT ST. BERNARD PASS.

IN reading the interesting article signed "A. M. M." and entitled "Alpines at the Grand St. Bernard, Switzerland" (August 12 issue, page 403), one is reminded almost of the very early writers on Alpine matters who always exaggerated the awfulness and the difficulties of snow ascents, in keeping with the lingering belief that dragons frequented the Alps, and feared that to ascend above the snow-line they were in perpetual risk of avalanches and tempests.

None of us enjoy correcting errors or misleading statements, however unintentional, in the published writings of fellow scribblers in the press; but sometimes it may not be well to let such pass unnoticed. A well known scientist once said at a meeting of journalists that perhaps 80 per cent. of the so-called scientific and geographical statements published in the daily press would not bear investigation. "A. M. M." will therefore bear with me when I venture to draw attention to a few points; particularly as THE GARDEN is kept by many,

It is recorded from only about four places in the whole of the Valais, and never from the district in question, and it is, perhaps, more frequent on the English chalk than in Switzerland. Its four-cleft corolla is much larger than the finest *campestris*, though in the Alps the latter is often very beautiful and most varied.

"Soon we were beyond the snow line." But "no more trees, nothing but grim rocks and thistles" does not indicate the line of perpetual snow, which is what is always meant by the snow line! Patches of snow were probably implied. On that side of the pass the snow line is somewhat low, but even the Hospice (8,110ft.) with its severe cold, is just below the line of perpetual snow. That the climate "kills any man who stays at the Hospice more than ten years" is, fortunately, an exaggeration. After twelve or fifteen years the Canons (Austin Canons Regular) usually descend to the mother house at Martigny.

"There, . . . waving his arm across the guarded frontier towards Savoy, 'lies Paradiso, full-till of the most wonderful flowers and strictly preserved as a hunting domain.'" The fact that the King of Italy has most of these extensive hunting domains should have reminded the visitor that it is long since Magenta,

GARDENING OF THE WEEK

FOR SOUTHERN GARDENS.

The Kitchen Garden.

Early Beetroots.—Do not allow these to remain too long in the ground or they will become very coarse and unshapely. Lift the roots carefully and remove to a cool store; failing such, the back of a north wall will do. A covering with leaves or bracken should be afforded when stored in this way.

Beans of the Runner and dwarf French type should be kept regularly picked whether immediately required for use or not. If left hanging on the plants they not only become tough and unusable, but they rob the plants of vitality, which greatly hinders the development of later Beans. After having been gathered Beans will keep in good condition for at least a week if placed on the ground in a cool cellar. It is an excellent practice to use surplus supplies as they become fit by storing in large earthenware pans to be drawn upon during winter.

Potatoes.—Lift all second earlies and mid-season varieties and remove to the store. Select a dry day for this work. Remove those required for seed to empty frames having a firm ash bottom thoroughly to ripen, and where, if necessary, they may be protected from rains until they are placed in storage quarters.

Cucumbers.—Give every encouragement to the young plants which are to supply fruits for the next few months. An abundance of water will be required during hot weather, and to keep the plants in good going order top-dress as soon as the roots make their way to the top. By careful ventilation the growths of the plants can be assisted to maintain their cleanliness and vigour, important points for winter fruiters.

The Flower Garden.

General Work.—The propagation of various plants must be pushed on to suit requirements, erring always by propagating too many than otherwise, for it is a simple matter to discard surplus plants when the results of the "strike" are assured. In addition to the propagation of the usual run of plants used for bedding purposes, the present time is suitable for inserting cuttings of a great many shrubs, using a sandy compost and a cold frame for the purpose. Beds and borders now need a great deal of attention to keep them constantly tidy and effective. Seed pods soon exhaust a great many of the plants so must not be allowed to form. Two plants in particular need watching for these if they are to be kept well up to the flowering standard—viz., Sweet Peas and Violas. These plants, in company with others, if showing any signs of exhaustion, should have a thin sprinkling of artificial manure lightly worked in around them and watered in, unless the weather renders the latter operation unnecessary. Keep Violet plants free from runners and if red spider is present give several good syringings with an insecticide, and use the hoe occasionally to keep weeds down.

The Hardy Fruit Garden.

Figs.—As the fruits approach the ripening stage care must be taken to see that they are secure from birds and insects. Select strong well placed growths for training in to provide next year's crop and at the same time cut out strong growing breast wood. The removal of this and the laying in of the former will allow plenty of light and air to penetrate, which is essential for the successful finish of the fruits.

Black Currants.—The crop having been cleared, the thinning of the bushes may be taken in hand if so desired. In dealing with this fruit the essential point is to induce and encourage good basal growths, and this should be borne in mind when planting, by getting them well down in the soil. Old trees in particular should have some of their branches which have carried fruit cut out entirely, thus concentrating the energies of the plants upon next year's fruiting wood. If some manure can be spared a good mulch applied now while roots are still active will do old or weakly trees a great deal of good.

Loganberries.—These require similar treatment to the Raspberries as soon as the fruiting season is over. Cut out all the old fruiting canes and lay in sufficient of the young ones as required for covering their allotted space. This is a most useful berry for immediate use or for preserving and those who wish to prolong its season and have not tried it on a north wall or against any support having similar aspect, would do well to try it. Should a few new roots be required they may be

secured by pegging down the ends of some of the shoots into the ground, or into pots if preferred. The young plants will be sufficiently rooted for autumn planting.

Fruits Under Glass.

Melons.—It is essential that the late plants be encouraged to make rapid headway, and to assist in doing this plenty of heat must be provided. Every bit of sun heat must be husbanded and the hot-water pipes kept sufficiently warm to prevent the temperature of the house falling below 70° to 75° at night. Having secured a couple of fruits to each plant suppress all unnecessary wood and bodd up the plants quickly to develop the fruits. Watch frame Melons carefully and see that the finishing fruits are clear of leaves. Where there is no pipe heat, cover the frames on cold nights with thick mats.

H. TURNER

(Gardener to the Duke of Northumberland),
Albury Park Gardens, Guildford.

FOR NORTHERN GARDENS.

The Kitchen Garden.

Spinach.—Thin earlier sown lots of winter Spinach to 4 ins. or 5 ins. between the plants and make further sowings of hardy sorts for picking during early spring.

Lettuce.—Prick out quantities of the more hardy sorts in sheltered quarters for cutting during October. Spare frames may also be utilised for this purpose. The advantage in employing frames is that they may be covered during wintry weather.

French Beans.—Where these are required during winter and the necessary facilities are available, a start should now be made by sowing in pots or in beds in heated pits. Osborn's Forcing and Sutton's Evergreen being commendable varieties for this purpose. Ventilation and watering will need careful attention so that no chill or excess of moisture may result. The ultimate success of this crop depending on the plants maintaining a sturdy growth.

Leeks.—Fill up any vacant ground available with Leeks, for although the season may be somewhat advanced, this desirable vegetable makes good headway during autumn and early spring, provided that the weather keeps open. Early lots now growing freely may be further assisted with regular waterings of liquid manure or soot water.

Fruit Under Glass.

Pot Fruit Trees that are required for forcing must be repotted now and every encouragement given them to mature their buds. Later pot fruits which have recently been cleared of their crop should be stood out of doors, as this will allow for proper ripening of the wood. Attention must still be given the trees as regards watering. Where it is intended to grow a few Peaches and Plums in pots for the first time, the following will prove suitable sorts for this mode of culture. Plums: Jefferson Gage, Denniston's Superb Gage, Kirke's Blue and the old Green Gage. Peaches: The Marchioness of Devonshire, Royal George and Dr. Hogg are good and reliable sorts. While Early Rivers, Pine Apple, Dryden and Humboldt may be chosen from among the Nectarines.

Late Vineries.—Keep a moderate amount of heat in the pipes at this period, more especially during sunless weather. Grapes now ripening should be given the necessary generous treatment so that they may develop berries of fine size and colour. Varieties such as Gros Colmar are at times rather difficult to get entirely black, but this may be caused by the lack of certain essentials in the soil. Where this is likely a note should be made so that the addition of certain chemicals, such as sulphate of iron, may be applied while the Vines are dormant. Over-cropping is often the primary cause of the fruits not colouring properly, while the exhausted condition of the border is also to blame at times.

The Flower Garden.

Polyanthuses.—Give the young seedlings every assistance to make strong, well developed plants before the bedding out period arrives, as these are among the most useful spring flowering plants we have. When preparing the beds give rotted dung so that healthy foliage and strong flower spikes may result.

Lilium candidum.—As bulbs of this charming old Lily come to hand, no time should be lost in having them planted out so that they may get well rooted before winter sets in. This Lilium seems

to thrive best on a light loamy soil, while on others it deteriorates quickly and requires replanting occasionally. On heavy soils leaf mould and sand should be added, while the addition of some well decayed manure for the roots to work into will add to the vigour of the plants. When grouped judiciously in the herbaceous border they add a brightness to the garden at a period when there is often a gap between summer and autumn flowering plants.

JAMES McGRAN

(Gardener to Sir Henry H. Houldsworth, Bart.),
Coodham, Kilmarnock.

GREENHOUSE AND CONSERVATORY.

Richardia africana.—Plants that have been standing at the bottom of a wall and partially dried off, should now be turned out, and all the old soil shaken off the roots. They should then be placed into small or large pots according to the purpose for which they are required. If for indoor decoration, small pots, 6 ins. or 7 ins. in size, generally prove most useful. On the other hand, if quantities of cut flower are required, it is best to use larger pots, in fact, for this purpose it is a good plan to put them into boxes. As they are gross feeding plants, a very rich compost is necessary. Dried or well rotted cow manure may be added to the potting compost, or failing this, some old Mushroom bed manure. After potting, stand the plants in cold frames and water sparingly until they have made some fresh roots and have started into growth. Plants that have been outdoors for the summer may be lifted towards the middle of September and put into suitable sized pots or boxes.

Humea elegans.—If not already done, no time should be lost in sowing seeds of this desirable plant. This sowing should form the main batch of plants for next season. This plant is generally considered difficult, but given reasonable treatment it is quite easy. Cool treatment and great care at all times in regard to watering being necessary. The plants should never be allowed to become pot bound, but at the same time over potting must be avoided.

Cyclamen seed should be sown thinly this month in pots or pans, and stood in a house with an intermediate temperature, in which the young seedlings are best kept all the winter. A temperature of 50° to 55° being suitable. It is essential to have fresh seeds of Cyclamen, as old seed takes a long time to germinate.

Calceolarias of the herbaceous type should also be sown at this time. The seed is very fine and should be very lightly covered. Cover the pots with a piece of glass and keep shaded until the seed germinates. Calceolarias of this type thrive best in a light rich compost, and enjoy cool moist conditions at all times.

Mignonette.—Well grown plants of Mignonette are always much appreciated for the greenhouse or for indoor decoration, but with the exception of a few market growers, one seldom sees it well cultivated in pots. Provided a few essential details are observed it is by no means so difficult as is generally supposed. Unless the loam is very heavy it is not wise to add leaf soil to the potting compost. Sufficient coarse sand or old mortar rubble should be added to keep the whole porous, and lime in some form is essential. The soil should be rammed very firm, adding a little at a time. As Mignonette does not transplant readily the seed should be sown directly into the flowering pots, which may be 5 ins. or 6 ins. in size, afterwards thinning out the plants to one or three in a pot. After sowing and watering, stand the pots in a cold frame and shade until the seed germinates.

Fuchsias.—Well grown specimen Fuchsias are very useful for conservatory decoration and now is a good time to propagate plants for next year's flowering. Plants that have been lightly pruned back, and are started in slight warmth, soon give young growth which may be utilised for cuttings. These young shoots root very readily. After rooting they should be potted off singly and kept growing steadily. If standards are required the stems should be run up to the desired height before stopping, rubbing out all side shoots as they appear. If pyramids are desired the main stem should not be stopped, and the laterals as they appear should be allowed to develop, pinching them occasionally to form the foundation of the specimen. Potted on as they require it and kept liberally fed, they should in their second year make specimens some 7 ft. to 8 ft. high. During their second winter they should be kept dry in a frostproof shed. Such plants may be kept for many years, but they are so easily and quickly grown that it is not necessary to keep them after their second or third year.

There are few plants that are better suited for planting in conservatories or greenhouses, for training under the roof or for furnishing pillars and rafters. Planted out they grow freely and flower with wonderful profusion all through the summer and autumn months. They should be kept

drier at the roots during the winter and should be pruned hard back during the spring. For this purpose free growing varieties should be selected, such as Monarch, Lord Grenfell, Royal Purple and Rose of Castile.

Royal Botanic Gardens, Kew.

VEGETABLES ALL THE YEAR ROUND: SEPTEMBER OPERATIONS

The first article on this subject was in the nature of a general review, in which an endeavour was made to point out specifically things of paramount importance, and brief reference was made to the routine operations due in the months of July and August. It is now proposed to call attention to the details which make their urgent call in September.

IN a sense this is one of the most difficult months and certainly it is the one in which the inexperienced grower is likely to stray from the paths of rectitude. He has before him the splendid fruits of his earlier labours and his anxiety is keen to seize the full advantage of them. He has to decide, for instance, whether he shall push on with Potato and Onion harvesting or with spring Cabbage planting. If the Potato and Onion yields are heavy the work connected with them may demand all the time available until the end of the month and the wisdom of getting them garnered cannot be questioned for one moment. Nevertheless, it would be a most serious cultural error to fail to get a proportion of the young Cabbages to their permanent positions by or before the middle of the month and it is therefore recommended, as a general principle, that when harvesting and seeding or planting come into intimate competition, the latter should be regarded as the detail for first attention.

As a matter of fact September brings comparatively little seed sowing and planting. As far as the former is concerned the chief plant is Spinach, of which a sowing may be made about the middle of the month; the site should be in good heart, yet not rich, quite open and the drills should be set 15 ins. asunder, the plants being thinned gradually until they stand an equal distance apart in the rows. Winter Spinach is always more or less a doubtful crop in a small garden, as while it succeeds easily in some it refuses to flourish in others, though the management may be just as admirable. Then, Spinach is frequently unappreciated at the table, usually, one dares venture to affirm, because the autocrats of the kitchen do not prepare it correctly.

Seedlings of all kinds from seeds sown last month must be wisely thinned out, whether they are to remain *in situ* or moved to other quarters, because it is only the sturdy, hardy youngster which has made all its advance from the seed-leaf stage onwards under the influences of light and fresh air that will pass safely and satisfactorily through the winter.

In planting, the crop of outstanding importance is that of spring Cabbages, which are among the most highly welcomed of all vegetables. Choose a piece of ground that has been thoroughly prepared by deep digging and which has had some rotten manure, but not a heavy dressing. Make it firm, either by allowing ample time for settlement or by treading, and pack the soil firmly to the roots; the distance both in and between the rows will necessarily vary somewhat with the variety, but it should rarely be less than 15 ins. in all directions. Put out a batch in the first week and a second a fortnight or three weeks later. Plant also winter Lettuces. Late Broccoles or Kales, too, must be planted, in case they are needed in spring, and again planting must be firm in rather richer ground.

Crops in full productiveness, Scarlet Runners and Vegetable Marrows are typical examples, must have proper encouragement by the closest possible gathering and by supplies of water and, perhaps, food if it is deemed essential. Peas coming on for late bearing must be adequately supported; have the soil between the lines frequently hoed and generous mulching on light, poor sites.

All Potatoes should come out this month and they will be taken in turn according to their seasons of finishing. Cut off the tops a few days in advance as it facilitates lifting and assists the skins to harden, leave the tubers on the surface for a few hours, again to allow the skin to harden, and place in a temporary store where it will be easy to examine them at the end of the month and prior to permanent storage in a dark, absolutely frost-proof place. If seed sets are to be saved, which is not advised, separate them from the ware at this point and store in full light, with abundance of fresh air and complete safety from frost. Onions must be given plenty of time in full light and air with provision for protection from rain, before going to a store where the bulbs are fully exposed to light and fresh air and perfectly protected from damp; it is the latter, and not frost, which causes such disastrous losses in winter and spring.

Gather Tomatoes closely as they ripen and remove the growing points of the plants, if it has not been done already. Judicious reduction of foliage to ensure the admission of light and air to the finishing fruits may be practised advantageously, but it is not desirable that it shall be carried to the uttermost limit.

W. H. LODGE.

The Miniature Torch Lilies.—Comparatively few amateurs seem to be aware of the existence of the dwarf "Red-Hot Pokers," yet they are among the most priceless adornments of the late summer border. For the rock-garden they are ideal, while they are also excellent for cut flowers since they last several weeks in water. One of the best is *Kniphofia Nelsoni*, a real gem, which raises its 18 in. stems above deep green grassy foliage in August, each flower-head a blaze of fiery scarlet. On a ledge of very light but good soil in full sun this delightful plant will maintain a succession of brilliant "torches" right through to November, and in doing so strike just the right note of colour to harmonise with the rich and mellow effects of the passing year. Rather earlier (June-July) dwarfer and more golden in its spires is the dainty little *K. rufa*, while still more diminutive but not less brilliant is *K. pauciflora*, unfortunately not too hardy everywhere. *K. corallina*, one of the prettiest of the hybrids, also flowers in summer and, as its name suggests, its flowers are a vivid coral red passing to bright yellow. *K. Pfisteri* is similar to, if not identical with, *corallina*, but some nurserymen catalogue several others. All are quite easily grown and though old-established clumps are

the most desirable, these dwarf Torch Lilies do not resent moving, strong off-sets flowering freely the first season after transplanting.

A fine Strain of Calceolaria.—One wonders that more has not been seen of that exquisite little plant, *Calceolaria gracilis*, both in the cool greenhouse and for planting outside in cool shaded beds. It will succeed splendidly in the open air if the seed is sown late and the young plants are kept very cool so that flowering is retarded until June or July. The plants should be a perfect picture for many weeks. It is generally used as a cool house plant and here it flowers in May and June at the same time as the huge herbaceous varieties, but—how different! In place of the large solid flowers, a bloom about twice the size of the ordinary yellow bedding kind, with all the attractive spotting and colouring one meets in the larger type. The strain is known as *Calceolaria gracilis*, John Innes strain, and a mixed packet will provide a good range of colours and markings. Indoor culture is precisely similar to that afforded the large herbaceous kinds, always taking care that not one single degree of heat is used more than is necessary to exclude frost. Where it is intended to try them outdoors, sowing should be deferred until early September, doing it then very thinly so that they may pass the winter in the box in which they were sown. When active growth commences in spring, take them up and pot off singly in small pots and transfer them at the earliest possible moment to a cold frame with an ash bottom. This provides ideal conditions of growth, for it ensures that they are both cool and moist, items that favour healthy growth and freedom from pests. Harden off carefully and do not hurry planting out. Select a position for planting where the sun cannot scald the foliage or parch the soil; they like a quiet shaded place where strong winds will not break them. Droughty conditions must not be allowed. The plants reach a height of about 18 ins. and terminate in little sheaves of flower, to which the name "*gracilis*" is most suitably applied.

A New Scarlet Ivyleaf Geranium.—For many years Scarlet Crouse has held undisputed sway as the foremost scarlet ivyleaf and one must feel a deep debt of gratitude for the splendid way in which it has filled the rôle. A new star has, however, arisen called Sir Percy Blakeney, which eclipses the old time favourite. It will take a little time, of course, for it to become available in quantity and the price at present is considerable, but admirers of good "ivy-leaves" should not overlook this valuable plant. The flowers are semi-double and a real scarlet, borne in large trusses, with great freedom. It grows and branches freely so that it is not a difficult matter to work up stock rapidly. It is a fine outdoor variety and should prove extremely valuable for window box and basket work.

A Greenhouse Climber.—Those looking for a delightful and unusual roof climber for the greenhouse should consider the claims of *Abutilon insigne*, which requires only a cool temperature to do well, is extremely graceful and almost always in flower. It makes leaves of moderate size, so that it does not prejudice the growth of plants on the staging beneath. The leaves are borne on green brown-haired stems, the flowers of good size with open mouths on hanging peduncles. These flowers are very showy, white in colour, but so heavily overlaid by heavy markings of purple and red as to be almost obscured. The growth should be allowed to hang loosely to display the plant at its best. It is a native of Columbia and flowers from late January until well into October. Propagation can be effected by cuttings at any time, as it grows all the year through, although it will bear hard pruning well during winter and breaks into new growth freely after this.

THE RHODODENDRON DELL

THE present month is the best of all the year for transplanting evergreen Rhododendrons and, indeed, evergreens generally. Large specimens should have first attention, as plenty of new root before the ground becomes chilled is more important in their case than it is with smaller specimens. The ease with which quite large Rhododendrons can be removed is one of their principal recommendations, since they can without permanent detriment be used as fillings among permanent plantings of trees and shrubs.

It may sound a little banal to say that the Rhododendron is a woodland shrub, but it is only too evident as one goes about the country that this fact is still but imperfectly realised. These glorious plants will, of course, with proper attention both before planting and during growth, succeed in the open, but they are easier far to grow, and much more effective when grown, if partial shade from trees can be afforded.

There is a sharp difference of opinion as to whether the old purple Rhododendron ponticum, the many new species from the "roof of the world," or the brilliant hardy hybrids are most suitable for woodland. Surely the answer to this depends upon the interpretation one places upon the word "woodland." If purely natural effects are aimed at; if, in other words, the woodland is a delightful accessory to the garden—adjacent to it perhaps, but not of it—then Rhododendron ponticum, with the addition possibly of such small species as Rhododendron Veitchii, the yellow Honeysuckle Azalea and—if the climate be suitable—some of the more robust and paler of the Asiatic species, will alone be suitable. With them will be associated plants either native to Britain or which at least one might consider wild without too wide a stretch of imagination. Wild effect cannot be obtained with plants of noticeably exotic appearance, such as Bamboos or Aralias, nor with plants commonly

met with in flower borders, however suitable for the purpose they might otherwise be. Hollyhocks, Phloxes, Rhododendrons, Anchusas and Antirrhinums would thus be ruled out.

In many cases, however, natural timber is taken advantage of to provide suitable effects in the garden proper, effects which, without any straining after the purely natural, are yet obtained by a certain informality of planting. In such case all and every species and variety of

Rhododendron sufficiently hardy in the locality may be employed, care being taken, naturally, not to associate closely together colours which clash, although the danger of this is not so great as one might suppose from the space sometimes devoted to the matter in books and articles upon the Rhododendron.

When it comes to a selection of suitable sorts for this kind of planting, there is wide scope for individual taste. Were it not so there would hardly be more than 130 hardy hybrids listed in John Waterer's list alone.

Some sorts there are about which there will be a pretty general consensus of opinion by those in a position to hazard one. Everyone, for example, will wish to include Pink Pearl and probably that grand old rosy crimson variety Cynthia, though here some will truly point out that the foliage is not quite all that might be desired. Mrs. E. C. Stirling and Lady Clementina Mitford seem fairly obvious selections, the former with pinkish lilac and the latter with peach-coloured flowers. Among whites there is something to be said for Mme. Carvalho, Mrs. John Clutton, Gomer Waterer, Minnie and George Hardy, while the comparatively small-flowered The Bride makes a satisfactory specimen and a pleasing spectacle the attached picture will testify.

The brilliant but rather difficult colouring of Bagshot Ruby and Doncaster makes a big appeal to some, while others would rather be without it. Those who like the colouring should grow both varieties, as they are quite different in habit of growth, Bagshot Ruby being the more erect. The magnificent Loder's White everyone will wish to have who can procure it, and few will wish to omit Lady Eleanor Cathcart or Lady Grey Egerton or the deep salmon Mrs. Holford and the still brighter Mrs. F. Hankey.

The writer has a partiality for heavily spotted and blotched sorts, such as Marchioness of Lansdowne, Pictum, Sappho, Sigismund Rucker, Lord Eversley, Lady Annetta de

A HUGE BUSH OF RHODODENDRON THE BRIDE.

IN THE RHODODENDRON DELL AT KEW GARDENS.

RHODODENDRON MRS. E. C. STIRLING.

BEAUTIFUL MOLLIS AZALEAS.

Traford and F. B. Hayes, but there are many who have no other than those approximating to self colour, though they may make an exception in favour of the almost picotee-edged Helen Waterer. Others, again, are specially fond of the mauve tints. These are lucky in some respects, for with that range of colouring almost invariably goes exceptionally handsome foliage. *Everestianum*, *lastuosum flore pleno* and *Princess Ena* are recommendable in this colour.

There is something more than a form of words in the idea of a Rhododendron dell. It is true that when the individual specimens attain a considerable size, backed, as they should be, by taller plantings, a dell effect is produced even if the planting was originally upon quite level ground, but it is none the less desirable to aid this effect by a certain amount of contouring where tree roots and other obstacles permit it. Anything in the nature of steep banks must at all costs be avoided, since the Rhododendron, being shallow rooted, is exceedingly impatient of drought, so much so, in fact, that exceptionally hot and droughty summers like those of 1893, 1911 and 1921 killed off large numbers on quite level ground, in cases where watering could not be done and little or no shade was available.

Decayed and decaying vegetable matter in old woodland is the natural soil for the Rhododendron, even rotten wood, so detrimental to most forms of vegetation, seems beneficial rather than harmful to the Rhododendron. It may be that decaying wood facilitates the increase of the fungus which it is now generally recognised is necessary to the growth of the Rhododendron. The usual method of providing this decayed vegetable matter is to form beds of often, pure peat. Leaf-mould is certainly equal and probably superior to peat for the purpose, and spent hot-bed manure or well rotted cow dung is, when available, excellent. One-third part of such humus-providing ingredients will ordinarily be sufficient, the remaining two-thirds being a light turfy loam. Such compost will grow sturdier, healthier plants than will pure peat.

The fine roots of the Rhododendron cannot penetrate stiff loam, but if this is nearly or quite lime free, "Rhodos" may be grown successfully if the drainage is closely attended to and a foot of the proper compost provided either above the natural soil or in lieu of the top spit of it. On soils with any appreciable lime content it is quite impossible to grow American plants satisfactorily, though there are a few—a very few—exceptions which serve to emphasise the rule. Such are *Rhododendron ferrugineum*, *Erica carnea* and *E. mediterranea hybrida*, and the *Arbutuses*, which shew no objection to lime even when plentiful.

With the Rhododendrons it is usual to associate *Kalmias*. These are noticeably less showy than their more popular relatives, but are valuable because they provide colour when the Rhododendrons are over. *K. latifolia*, the Mountain Laurel, is the quickest growing, largest in leaf and latest to flower. Interest later in the year may readily be provided by planting various Lilies in groups among the bushes. Soil, shade and setting combine to make the Lilies do well and shew themselves to best advantage.

Many people like to associate the *Mollis* and *Ghent* Azaleas with Rhododendrons. A sure eye for colour is needed if this is to be managed successfully, though some of the softer yellow Azaleas go well with the more richly toned Rhododendrons. If Azaleas are available "on the spot," there is no need to wait until the leaf falls to remove them; they may be transplanted right away. The writer well remembers that somewhat unexpected building operations necessitated the removal in early August of a large specimen *Azalea mollis*, the ground being dust dry at the time and the weather droughty. The specimen had not previously been moved for probably twenty years, yet it transplanted perfectly and flowered much as usual not only the next spring but the one following!

SOME HARDY MALLOWS

The persistence with which that peculiar shade of silvery bluish rose, sometimes called mallow pink, runs through the whole of the Malvaceæ is the reason for treating several distinct genera together.

HARDY Mallows might well be thought to refer to the genus *Malva* but in the following notes it is intended to refer also to the closely related genera *Lavatera* and *Sidalcea* and the also related *Hollyhocks* (*Althæa*). The *Hibiscus* also are nearly related, but as shrubs—and stilted habited shrubs at that—hardly associate with the rest.

Of the true Mallows (*Malva*) the most useful species are *M. moschata* (the Musk Mallow of our own countryside) and *M. Alcea* with the very distinct sub-species *M. A. fastigiata*. The pure white variety of the Musk Mallow is perhaps even more charming than the typical *Malva Alcea* is a taller species, with the characteristic Mallow colouring at its deepest and, consequently, most "difficult" tint. *M. A. fastigiata* once classed as a species—*M. Morenii*—is more upright growing and the flowers are reddish. *Malva campanulatum*, occasionally met with in very mild districts, is an admirable dwarf species, but tender.

Of the *Lavateras*, which may be described as sub-shrubby Mallows, the two best are probably *L. Olbia*, which is tall enough for the back of the border and bears large and showy flowers in the utmost profusion, and the more slender, but perhaps even more beautiful, *L. thuringiaca*, which, excellent in the border, is even more admirable when naturalised in woodland or on wild banks where it grows as readily as the Musk and Marsh Mallows. *Lavatera trimestris* is an annual—a much improved annual be it said—not unlike *L. Olbia* in appearance and valuable for filling temporarily the gaps which always occur even in the best managed gardens. It may be had with white flowers or with those of some rather deep shade of Mallow pink. The best and deepest form of this is probably that known by Messrs. Sutton as *Loveliness*. The biennial species, *Lavatera arborea* is often used for "sub-tropical" bedding but is fairly hardy and may be sown outdoors in autumn in suitable spots. There is a rather handsome variegated form.

The Greek Mallows (*Sidalcea*) so called, as the Irishman said, "because they come from North America" are perhaps more graceful than most of the *Lavateras*, having smaller flowers on spikes somewhat reminiscent of the *Hollyhock*. Though

perennial the *Sidalceas* are not long lived plants but they are readily renewed from seed. *Sidalcea* *Rosy Gem* is one of the best. It has a pure white counterpart listed as *S. candida*. *S. malviflora* is considerably larger both in plant and flower, its flowers are deeper in colour, bordering on purple in fact. More pleasing in colour is *S. Listeri*, with soft silvery rose flowers. *S. spicata* is another worth growing, it produces purple rose cups.

Of the *Althæas*, the varieties usually grown in gardens are the true *Hollyhocks* (forms of *A. rosea*), but others are sometimes met with in gardens, and

THE SILVERY PINK HOLLYHOCK PALLING BELLE.

one, the Marsh Mallow (*Althæa officinalis*) is an English wild flower, and a very beautiful one. *A. ficifolia* is the fig-leaved or Antwerp Hollyhock, with beautiful single yellow flowers. Of more branching habit than the forms of *A. rosea*, it is a short lived plant, being practically if not actually a biennial.

The double Hollyhock in its many colour forms is the product of centuries of endeavour, but the now popular single forms are equally beautiful and more suitable to many situations. A deep rich well cultivated soil is necessary if the Hollyhock is to be seen at its best. Stately port should be its chief characteristic, and this can only be obtained if good culture obtains. Even for garden decoration

it is unwise to leave more than, say, four spikes on even the strongest plants, as a multiplicity of spikes destroys the vigour of the plant. The thinning should be done as soon as the plants have attained a height of a foot at most. Less vigorous plants should be thinned to two spikes or one, according to their strength or weakness.

Named varieties of Hollyhock are very beautiful, but for garden decoration it is surprising how true to colour and how good in form seedlings come. Seed may be sown now, and if the young plants are pricked out, grown on and potted off, and planted out next April they will all flower well next summer and early autumn. The crimson and soft yellow varieties are invaluable for associating with blue *Delphiniums* and such like while the silvery pink and rose shades are invaluable in a section of the border devoted to Mallow pinks and dilute purples and grey foliage.

When thinning growths in spring it is well to save the thinned shoots for cuttings, which root fairly readily with a little bottom heat.

On stiff soils, Hollyhocks often die off in winter. This may largely be prevented by removing the heavy loam from around the collar of the plant and replacing it with sharp sand or clean and sharp, but spent ashes. Staking is very necessary with Hollyhocks as the great spikes easily twist off at the crown but it is unnecessary to supply tall stakes. If the stakes, when driven in, stand 3ft. out of the ground, this should prove ample.

The Hollyhock may be and often is grown in beds as shewn in the accompanying picture of that beautiful variety *Palling Belle*. This method of culture should never be adopted however, if trouble is experienced with the Hollyhock Fungus (*Puccinia malvacearum*) which always first attacks the lower leaves. Dusting the undersides of the leaves with flowers of sulphur or spraying with liver of sulphur is a wise precaution against attacks by this pest, or Messrs Vert of Saffron Walden who specialise in this flower, supply a very efficient powder for the same purpose. None the less if trouble has previously been experienced with the fungus, it is wiser to reserve the Hollyhocks for grouping at the back of the herbaceous border or way back in openings in the shrubbery. Dying foliage on the Hollyhock is not always caused by rust, which is easily distinguished by the circular spore-cases on the undersides of the leaves. Red spider also is a serious enemy and in dry seasons often does immense damage. Good culture will do much to minimise the trouble but it is a wise precaution to soak young plants in soapy water for an hour or so before planting out, as red spider is but too prevalent under glass. Syringing the plants each evening in hot weather serves the double object of encouraging growth and keeping down thrips, which also are sometimes very troublesome.

If a large stock is desired of a particularly good variety (unaffected by rust), a quick way of increasing it is to use any available side shoots or small spikes and cut them up into lengths with a single joint and eye to each and keep them close, and, of course, shaded from sun heat. Almost every cutting should break and produce a young plant which, properly treated, will flower well the following season.

FORTHCOMING EVENTS.

September 5.—Royal Horticultural Society's Fortnightly Meeting. Caledonian Horticultural Society's Meeting.

September 6.—National Dahlia Society's Annual Show, to be held at the R.H.S. Hall.

September 8.—Paisley Florists' Society's Meeting.

September 9.—Ringwood Horticultural Society's Meeting.

BULB ORDERS.—II

More about Daffodils—Varieties for Pots—A Garden Twelve—Tulips—The Influence of Fashion.

AT the end of my first instalment of Bulb Order notes I got upon the subject of Daffodils and I suggested a trial of Cervantes for planting in pots as a first early and the investment in a little stock of Comtess of Southesk for growing on for providing some dainty cut flowers.

I thoroughly sympathise with poor Persephone as Jean Ingelow depicts her wandering on and on in the "Meadows of Enna" as beauty after beauty caught her eye.

"Lo! one she marked of rarer
growth
Than orchis or anemone;
For if the maiden left them
both,
And parted from her com-
pany,
Drawn nigh she deemed it fatter
still,
And stooped to gather by the
rill
The daffodil, the daffodil."

Persephone, by Jean Ingelow.

Anyone, like Persephone, could easily wander on and on and never know where to stop when engaged in singling out some of the best. There are so many varieties in the modern list of any firm that rather makes a speciality of the Daffodil. One must become a double distilled eclectic to make at all a decent job of it. Let me give a concrete example. We have two singularly beautiful small cupped Leedsii's in White Lady and Evangeline. In selecting, say, a dozen different varieties for the garden, there is hardly room for both. Which is to be taken, and which left?

Again to take an extreme case, let me suppose, out of all the varieties and species of Daffodils produced by wanton Nature or by the skill or luck of man, I was only allowed to have three in my garden, which would I select? If to-day I sodd Emperor, Barni conspicuus and Poetions recurvus; to-morrow it might be Emperor, White Lady and Virgil.

In what follows I am just going to make a few suggestions of varieties that I think are worth a trial. In a general way almost all the red eyes and red-edged cups and eyes are much more beautiful under glass, flowering as they do when the sun has considerably less power, than when their natural time comes when they are grown out of doors. Lady Moore is extraordinarily good in a greenhouse, but except for a few short hours it is nothing in the open.

Firebrand with its deep red cup is among my special favourites under glass, so too are Blackwell, Sunrise, Homer and the new poetaz Orange Blossom. This last is the result of a similar cross to that by means of which Van der Schoot produced his well known Elviza, Alsace and Jaune à Merveille but I am told the seed bearer was the Tazetta (Polyanthus) variety and not the Poetions as in the old strain. Anyhow the substantial white perianth with its rich orange spreading centre makes a most

attractive flower. In all but the southern parts of England it must have ample protection if it is planted in the open. So many people object to the strong perfume of the ancient Tazettas, and always give them a miss when making out their order on this account. These once all-important varieties, which alone were noticed by George Glenny in his little book on the properties of flowers in the middle of last century, seem to be slowly dropping out of favour and being supplanted by the new poetaz. I should like to mention Admiration, Helios and

THE FRAGRANT POET'S NARCISSUS.

Orange Cup as three good ones well worth a trial. The time will come when the Giant Leedsii will be cheap enough to use for pot work—Norah Pearson and Capella are two which would give a good run for anyone's money. But here I am, wandering on and on and doing exactly what I did not intend to do, and I have only got as far as pots! *Pecavi*. To make amends, I will just give a list of what I might order if I wanted a good dozen for my own planting in the open: Emperor, Argent, White Lady, Mrs. W. O. Wolsley, Virgil, Kingsley, Great Warley, Blackwell, Lucifer, Steadfast, Weardale, Perfection and the Rugulosus variety of Campanelle Jonquils.

And now to come to the Tulip family. Mistress Daffodil and old Mother Tulip, like the old woman who lived in a shoe, have so many children that the perplexed gardener does not know what to do when

he sees the tens of varieties in one of our modern catalogues. No one wishes to order them all. If, in the days of John Rea and Samuel Gilbert—that is in the middle years of the seventeenth century—it was "which Agot?" or "which Paragon?" so now it is "which Cottage?" and "which Darwin?"; or, as glass-houses have become so common, "which must it be for pots and which for the garden?" My purpose once again—as in the case of the Daffodil—is neither to give detailed selections from the various sections into which the Tulip family has been divided for gardening purposes (see the R.H.S. Tulip book), nor to point out with any measure of fulness which will be the best for rock-work, greenhouse or open ground, but rather in a haphazard sort of way to suggest for the consideration of purchasers some of those which at the present appeal very strongly to myself. I have recently received Sutton's 1922 Catalogue and on the very first page among the very select selection of "new and interesting bulbs possessing exceptional merits" I find three Tulips, Fireglow (syn. De Wet), The Fairy and Canary Queen. I know the first and last ones very well indeed. Few varieties are more beautiful under glass if only they are not hurried into a too-early flowering stage. Few are more taking in the open garden. I can never forget my first sight of Fireglow decorating a typical room in a Woman's Industrial Exhibition at Amsterdam and how excited I became until I had found out what it was and where it came from. It is a sport of the famous Prince of Austria in which the yellow and red colouring has become separated, and on close inspection is seen to form a very delicate network, while at a distance the effect is that of a very bright orange red. Canary Queen, very tall and stately and so refined looking with the dainty lemon edging of its delicate primrose coloured petals, is a gem of the first water under glass, and it is just as pleasing in the open, only the distinction between the edge and the ground colour is not so clearly brought out. It blooms about the same time as White Swan. The Fairy, which is described as a glistening white Parrot Tulip, delicately tinted with rose, is entirely new to me. I have never seen it, but Fantasy, another novelty of the same type I have seen. It is a sport or development from the well known Clara Butt and has all the charm of that beautiful flower in its colouring. To those who like the Bohemian deshabille of the Parrots, I commend this startling new comer. How is it that every rock garden in the length of the land has not its patch of the bright little yellow and white Tulipa dasystemon? "Where are you going, my pretty maid? I'm going a milking, Sir, she said." That's just it. It is the innocent looking freshness of dasystemon that is so charming. Everything is influenced by fashion. Tulips are no exception. It was all stripes, feathers, and flames when the belles of seventeenth-century Paris wore them in their dresses. It was the same in the first half of the last century when the drab lives of many artisans in northern England were relieved by the pleasure of their culture, culminating in the struggle at the Ring o' Bells for the time-honoured copper kettle. Now it is selfs. We call them Cottage varieties and Darwin varieties. The popular taste just now I think is for mauves, such as Melicette, Euterpe and Oliphant—three of the very best—and pinks such as the ever popular Clara Butt and Sophrosyne and Suzon. The year, however, the head gardener of a neighbouring Hall came along and said "No colour was like bright red in a garden." I pointed out Goldfinder, Scarlet Emperor and Marksman. He quite agreed he could not have much better varieties, although it is very likely he would have wished Goldfinder to be rather bigger than it is. The Darwins, Home and North Dakota, might also be included among

the very brilliant scarlets. They come very near. It is strange how our love for past favourites suddenly revives. I have been quite dotty over Petrus Hondius this year. It must be a case of great minds etc. etc. for in Pearson and Sons 1922 List I read, "Has been much admired of late."

It is described as "a rich rose, and very beautiful and quite distinct." I do not grudge old Hondius this fascinating flower, although he was somewhat of a Jeremiah over the growing taste for Tulips. His warnings fell on deaf ears, and the mania (1635-37) was the result. JOSEPH JACOB.

The EVOLUTION of the GLADIOLUS—I

The Primulinus Hybrids.

THE hybrids of *Gladiolus primulinus* are legion. Fashionable flowers of the moment, they have inspired hybridisers the world over, and the ease with which they can be raised from seed has brought many amateurs into the ranks of the producers. But while these hybrids are certainly fashionable flowers of the moment, their popularity is not for the moment only. They have come to stay and to increase in popular favour year by year. The happy discovery of the primulinus species infused new interest into the cultivation of Gladioli. Its introduction has given grace to a family of plants which hitherto wrested attention by a massive and formal display of gorgeous colour, but which failed to win the sympathies of many people because of a too compact and rather stiff habit of growth. Not only are the flowers of the primulinus species arranged more loosely on the spikes, but the latter themselves are more slender and tapering, giving altogether a more refined aspect to the plant, which is further enhanced by the hooded formation of the bloom and the extreme delicacy of the yellow, orange and saffron tints so frequently found therein. So far the primulinus hybrids have

remained in a class by themselves, distinguished from all others by the characteristics mentioned, but what the future holds for them is a matter of some concern to interested growers. Already certain varieties listed as primulinus hybrids are barely distinguishable from the large-flowered section, and if the public taste, which so often sacrifices the more refined pleasures of appreciation for mere size, is going to fall into this error as regards these hybrids, then before many years we shall have only one word to describe every section of the *Gladiolus* family and that one word will be merely—*Gladiolus*. However, that time is not yet, and it may be long delayed by the discriminating taste of originators themselves. Practically the only path along which evolution of the *Gladiolus* has progressed is by means of crossing the varieties and species in our possession and the resulting selection from the seedlings obtained thereby. Until only the last few years amateur gardeners seem to have been entirely ignorant of the ease with which Gladioli can be raised from seed. At our own place we flower hundreds of seedlings six months after sowing and have repeatedly shown the flower spikes thus grown at the fortnightly meetings of the Royal Horticultural Society.

I have no hesitation in giving our friends in the United States premier place in the production of new varieties of the primulinus hybrids. Those illustrated here are both of American origin. *White Butterfly* is a novelty of 1922 and is perhaps the purest white yet attained in this section. *Argo*, styled the primulinus *Myrtle*, is a lovely salmon rose with pastel cream throat, large enough in flower, but lacking nothing in graceful bearing and a fine fresh looking colour.

It is not my intention to give a catalogue of varieties, but a selection, taken as the flowers are open, of those that most appeal to me, would in all probability also please the eye of average colour sense. As we have already touched on American varieties, we might here note *Butterboy*, which gained an award of merit for us a week or two ago. This is a large well hooded flower of almost buttercup yellow, with just a hue of dark brown down each of the lower segments, very handsome.

GLADIOLUS PRIMULINUS WHITE BUTTERFLY.

Golden Gleam is of richest orange saffron with more of the former than the latter and an intensely bright shade at that. What a rare sunny splash of colour this makes in the border! *Alice Tiplady*, thoroughly established as one of the primulinus "classics," has something of *Golden Gleam* colour, but here the saffron tinge predominates. This one should always be included in a collection, as so should *Altair*, one of the loveliest of the lot, described as salmon saffron, anyway a real beauty. Then there is *Eden*, pale salmon pink deepening to the edges, the lower segments being mostly cream with a picotee edge of bluish pink, a favourite this with all who see it. *Utopia* and *Zenobia* are both superbly showy, the former in shades of salmon and the latter richest orange-red, near to a scarlet. *Salmon Beauty* is very fine, the yellow throat setting off the wing colours to perfection. *Cantopus* is a very lovely pale yellow, deeper in the lower segments and in the same class are *Anita* and *Elberton*, yet each is quite distinct. *Topaz*, salmon buff, very pretty form, and *Enon*, creamy yellow and orange, are lovely in the softer tones and *Firefly*, *Capella*, *Midsummer Dream* and *Sonia* are conspicuous for their strong shades of red and scarlet.

Among the English raised hybrids, Major Churcher claims *Woodcote* and *Otranto*. These I consider are two of the finest sorts yet brought to light, but the same gentleman has some very choice seedlings in the making. *Woodcote* is the softest of coral scarlets, with a large cream yellow blotch, perfect in form and well placed on the spike. *Otranto* is a maize yellow with beautiful red lines in the throat and just a flush of rose on the shoulders of the upper petals; one of our best hybrids. Messrs. Kelway have some fine varieties in their "Langrim" group, of which *Lieutenant Kelway*, *Ella Kelway* and *Superior* are noteworthy. J. L. GIBSON.

GLADIOLUS PRIMULINUS ARGO.

GLADIOLI AND OTHER HARDY FLOWERS AT VINCENT SQUARE

ON entering the Royal Horticultural Society's Hall on August 22 the visitor felt that it was a Gladiolus Show, for large quantities of handsome spikes seemed to dominate there, and, while it was seen that there were plenty of other flowers, the many exhibits of Gladioli claimed most attention. The most attractive collection was by Messrs Sutton and Sons and this was set up with all the skill and taste expected from the Reading firm. The glorious vivid colour of such sorts as Red Emperor, Captain Fryatt and Electra was freely remarked upon, as also was a large bowl of the glowing salmon pink Prince of Wales. White Giant, Brimstone and the rich yellow Lucie were equally admirable representatives. These were all of the large-flowered type, which also predominated in a large collection by Messrs. Kelway and Sons that included many of the graceful primulinus hybrids. Of their large-flowered sorts many visitors were fascinated by those which have an intense blood red blotch on the lower segment in such startling contrast to the milk white or creamy yellow of the remainder of the flowers. Notable examples of these are Golden Dawn, Lady Fare, Sunspot and Lady Montague.

The primulinus hybrids were especially beautiful in a collection by Messrs. Lowe and Gibson, who included the variety Butter Boy, which recently had an award of merit. Maiden's Blush, Altair

and Niobe were also delightful. A couple of blue sorts—Duc de Massa and Blue Isle, were very striking in Major Churcher's collection, and primulinus hybrids were also well shewn by Messrs. R. H. Bath, Limited.

Goodly collections of Dahlias were rather expected, as the valuable Cory Cup was offered for the best representative exhibit, but only Messrs. J. Cheal and Sons entered for the Cup, and by some unfortunate muddle their exhibit was considered in relation to the border flowers by the committee, and was even described officially as consisting of hardy plants. Among the various types of Dahlia on show was the Anemone-flowered Mons. C. Dupont, which many thought was a new type, but it was raised

THE ANEMONE-FLOWERED DAHLIA MONS. C. DUPONT.
Flowers of a purplish crimson shading.

THE FRAGRANT BLOOMS OF MAGNOLIA GRANDIFLORA
EXMOUTH VAR.

in France some years ago. The compact flowers are of fascinating purplish crimson shading. Messrs. Jarman and Company also had some Dahlias, but their Sweet Sultans were even better.

The general floral exhibits included Heleniums, Hollyhocks, Phlox and such, while Mr. C. Turner had a vase of most beautiful blooms of Magnolia grandiflora Exmouth variety, which flowers at an earlier age than the species.

Among the Orchids, the chief exhibit was the wonderful gold medal collection of Lælio-Cattleyas by Baron Bruno Schröder. There were 100 plants, which the committee considered to be the finest ever shewn, and Mr. Shill, the gardener, was awarded the silver-gilt Lindley medal for cultivation.

Roses and Carnations were again shewn in great beauty. Among a display of Roses by Messrs. D. Prior and Son there was a vase of Ideal, a new velvety dark crimson little Polyantha which seems quite distinct. Mr. Pemberton shewed the value of massing several of his free-flowering sorts, such as Vanity, Aurora and Mermaid.

Great interest was centred in the excellent exhibit of Black Hambro Grapes from the gardens of Mr. J. A. Nix, Tilgate. Each of the sixteen bunches was very shapely, and the berries were sloe-black, thus indicating expert cultivation. Messrs. Daniel Brothers had large mounds of gathered fruit as well as fruiting branches of their September Black Currant. This variety, which received a first-class certificate last year, bears immense berries in great profusion. The fruits are of excellent flavour. An uncommon exhibit was the splendid collection of vegetables shewn by the members of the High Wycombe and District Horticultural Society. Practically all seasonable vegetables and salads were represented, the Peas, Beans, Carrots, Leeks and Potatoes being of very high quality.

NEW AND RARE PLANTS.

Aster hybridus luteus.—This moderately dwarf herbaceous plant will appeal to those who like a mass of bloom rather than individual flowers of fair size. It makes dense, flattish

heads of yellow flowers. The foliage is almost negligible—the leaves are short and narrow. Award of merit to Mr. Amos Perry.

Gladiolus Rarity.—A medium-sized spike, well furnished with widely expanded flowers of fascinating soft shell pink colour. The lower segment has a crimson-lake blotch. Shewn by Messrs. Lowe and Gibson.

Helianthus multiflorus Loddon Gold.—In general characteristics this is a glorified form of the old perennial double Sunflower. The flowers are much larger than those of the old favourite, and they are of a rich yellow. It is distinctly a plant for the back of the hardy flower border. Award of merit to Mr. Thomas Carlile.

Dipteronia sinensis.—It is rather difficult to understand why this deciduous tree received an award. It has no floral beauty and its chief attraction must be the clusters of flattish pairs of winged seed vessels, which are little, if any, more ornamental than those of the Wych Elm or the Hop Tree (*Ptelea tritoliata*). The pinnate leaves, which are about oins. long, are decidedly less ornamental than those of many other trees—the Tree of Heaven (*Ailanthus glandulosa*), for instance. *Dipteronia sinensis* was introduced by Wilson from Central China in or about 1900. It becomes a small tree about 25ft. in height. Award of merit to the Hon. Vicary Gibbs.

Rosa Sweginzowii.—This is an ugly name for a spreading Rose that is very handsome when in fruit. The bright crimson haws are of inverted urn-shape and glow with colour, and the neat, tern-like leaves are somewhat like those of *Rosa sericea*. The plant was raised from seed collected by the late Mr. R. Farrar. Wilson is of the opinion that it is a geographical form of *R. setipoda*. Award of merit to the Director, R.H.S. Gardens, Wisley.

Lælio-Cattleya Golden Light.—Three large blooms of this handsome new hybrid were shewn. The sepals and petals are coloured reddish orange, while the lip is tinged with ruby-red. Award of merit to Lieutenant-Colonel Sir George Holford.

Lælio-Cattleya Idina.—A very beautiful bloom with mauve sepals and petals, a violet-purple lip and yellow disc. Award of merit to Messrs. Flory and Black.

Lælio-Cattleya Sargon.—The broad sepals and petals are heavily stippled with rosy mauve and the lip is ruby-crimson. Award of merit to Lieutenant-Colonel Sir George Holford.

NEW DAHLIAS.

The Joint Dahlia Committee met for the first time and, following the recent custom, selected the best varieties for trial at Wisley.

Bronze Star.—This appears to be rather a poor type of Star Dahlia. The flowers were of indifferent shape and hung their heads. The colour is a bronzy apricot. Shewn by Messrs. J. Cheal and Sons.

Estacy.—The name is obscure, and one wonders whether Estacy is not meant. However, it is a beautiful flower of large size and, although a Cactus variety, much like the Decorative type. The colour is a bright mauve with a milky white centre. Shewn by Messrs. Stredwick and Son.

Gatton Star.—Unlike the first-named variety, this is a worthy addition to the not inconsiderable number of elegant Star Dahlias. The colour is orange-buff shaded with purplish mauve. Shewn by Messrs. J. Cheal and Sons.

Megantic.—An excellent exhibition Cactus Dahlia of perfect form. The rolled petals have incurving tips and the pale yellow colour of the unexpanded florets develops into pale apricot.

Noble.—An immense but not coarse Decorative variety. The shapely blooms are borne on stout, erect stalks, so that it should be a good sort for

THE BRIGHT CRIMSON HIPS OF ROSA SWEGINZOWII.

the garden as well as for house decoration. The warm scarlet colour pales towards the tips of the petals.

Signal.—This is a highly decorative Cactus variety of star-like appearance. The pale brick-red rolled florets are almost straight.

Siren.—A medium-sized Decorative bloom of perfect form. The broad petals are regularly stippled with rosy mauve on a creamy ground.

Skyrocket.—A handsome Cactus variety which has long rolled florets that curve inwards at the tips. The colour is rosy purple, with a golden bronze centre.

Yellow Queen.—This rich golden yellow Decorative variety is of immense size, but perfect form and possesses good substance. The last six varieties were shewn by Messrs. J. Stredwick and Son.

THE LATE SUMMER BORDER

THE herbaceous border is very often less of a success at this season than it is earlier in the summer. It is quite easy to have a fine display of flowers in June and July, but when that is over there are often sad gaps to be seen, and the general display of flowers is much diminished. It is well, therefore, to consider the border very carefully at that season of the year—note book in hand—and to make careful note of the arrangement of plants as regards colour, height, form, season of flowering and numerical proportion, since the less left to the memory the better. It is so easy to forget, long before planting time comes, the many little differences in shades and manner of growth on which the real success of the planting for the next year will depend. A few fortunate people have the colour sense exceptionally well developed, and the colour memory equally so, but the majority cannot safely trust to these, and are wise to have a good note book, and to try various combinations of flowers either in vases or held loosely in the hand. There will often be surprises. Even plants of exactly the same shade of colour as regards the flowers do not always make good neighbours; their manner of growth and the actual form of the flower itself may prevent an entirely satisfactory combination.

Sufficient attention is, indeed, seldom paid to this point; colour is the chief study, and only a comparatively small notice given to the form in which that colour is displayed beyond inquiring the height of the plant. Numerical proportion, too,

is seldom considered very much; the usual plan is to put a patch of each plant, varying it according to the size of the plants and the number of them at the gardener's disposal. But a combination of colours to be quite satisfactory will depend largely on the numerical proportion of each shade in the mixture. The writer was greatly struck, earlier in the season, by this point when looking at a long border in a large garden. The elderly head gardener, a man with an unusually good eye for colour, said that it had really been a chance planting, but seemed so successful and uncommon that he had had it left undisturbed. It was a daring mixture of red and pink Valerian and double scarlet Geum. The crimson Valerian appeared to predominate, and the Geum was considerably in the minority, and the effect was gorgeous, but would in all probability have been quite spoilt had either the scarlet or the pink been the principal partner.

Of course many people work closely to a colour scheme that does not admit of experiments of this sort, but in these days when variety is so much appreciated, and there is a great love of rather bright and uncommon mixtures of colour, it may often be possible to let the herbaceous border benefit.

Phloxes are perhaps the mainstay of this border, but they need careful arrangement both as regards colour and height if they are to make a thoroughly successful effect. Shades, beautiful in themselves, may be "just wrong" grown next to an equally beautiful one which does not quite tone in,

and it would be very easy to waste half the effect of those whose growth is short by putting them behind those of a taller habit. Hollyhocks, too, where they can be successfully grown, will make a splendid effect in this late border.

Other plants which should not be forgotten are *Gypsophila paniculata* (the double flowered variety being the best and showiest), *Anthemis tinctoria*, *Helium autumnale* var. *magnificum*, *Helium cupreum* and the tall growing *Helium Golden*

Glow, *Rudbeckia digitata* (another tall yellow perennial), *Statice latifolia* and *Aster acris*. Dahlias of all sorts of course, as well as Pentstemons, can be included, and will help greatly to enliven the border, but they both require more attention than many people care to give to the occupants of the herbaceous border.

Lastly, it should not be forgotten that the easiest way to avoid the possibility of large and unsightly gaps is to arrange each kind of plant, not in the

usual rather rounded clump, but in a long and rather narrow stretch or "drift," as Miss Jekyll calls it. Then when a plant has finished blooming and can be cut down, its neighbours, if judiciously chosen to follow on in the flowering period, will spread and, to some extent at least, cover the space. This plan, however, certainly calls for more care in arrangement of colours, since the plants intermingle through the border in longer lines. The effect if the job is well carried out, will be far better. A. E. W.

GREENHOUSE PLANTS

Every year provides additions to the already long list of lovers of greenhouse plants. The following, largely tabulated, information should therefore prove helpful.

IT is only in our large nurseries where it is possible to have a fairly complete collection of greenhouse plants. Although there are many kinds besides those in the table, the latter contains the most suitable ones for a beginner and will prove to be a helpful guide.

COMPOSTS FOR CUTTINGS AND SEEDS.

Only a small bulk of soil is needed for the above, so that it is essential to success that the ingredients be of the best. Let no one be tempted to use ordinary garden soil, it is far better to purchase a bushel or two of suitable soils are not available at home. Where it is convenient to procure sound peat, leaf soil and fibrous loam, these should always be kept in stock for use as required. Well rotted loam, two parts; leaf soil, one part; and coarse sand, one part, will generally speaking be a suitable compost both for rooting cuttings and for raising seeds. For the benefit of Palms, more loam and less leaf soil must be used. For such hard-wooded plants as Azaleas, add more leaf soil or peat and less loam. The general mixture as apportioned above will do nicely for the general run of plants such as Zonals, Abutilons, Cannas, etc.

Seed or cutting pots should be clean inside and out, the crocks also; the sand should first be washed and dried; for seeds the pots or pans must be filled with the prepared soil, watered and then left to drain for one hour before sowing. For cuttings the soil must be in a medium state of moisture and the inserted cuttings watered in. The soil should be firm and well surfaced with sand.

The average length of a cutting is 5ins. The cuttings should always be severed with a sharp knife immediately below a joint and the leaves from that joint cut off.

REPOTTING.

The transplanting of seedlings or the repotting of rooted cuttings should be accomplished by first transferring them singly to small pots (in the case of cuttings) and then, as roots become plentiful, to larger pots, till the final potting is reached. A too big shift—from a tiny pot to a large one—is wrong. The general run of seedlings are all the better if first transplanted into other pans or boxes several inches apart before the actual potting of them begins. Finer composts for seeds and cuttings and gradually coarser ones, as the plants are shifted to larger pots, should be the rule.

WATERING.

Seedlings and cuttings should be watered with a good watering-can, and not in full sunshine; some shade will be required when the sun shines brightly. Early morning and evening are the best times to apply water in spring and summer, and early morning only during the late autumn and winter

months. Tepid water and rain water are better than cold or pipe water.

VENTILATION AND TEMPERATURES.

Sudden rises of temperature are harmful. In the winter the day temperature should be from 40° to 50° F., the night temperature not falling much below 40°. Owing to sudden changes from comparatively mild to severe—often frosty—weather, there should be a range of 10° in a greenhouse; it is better to be rather low, with safety,

than high, with the aid of very hot pipes, during frosts.

The ventilators must be used judiciously to regulate the internal heat, opening to prevent it becoming too hot and closing to husband sun heat and so prevent a sudden lowering of the internal heat. Cold draughts must always be guarded against, but especially in spring. In summer time both ventilation and temperatures are more easily managed. GEORGE GARNER.

HOW TO RAISE AND TREAT USEFUL GREENHOUSE PLANTS.

Kind of Plant.	Method of Propagation.	Date of Sowing or Striking.	Pots for Final Potting.	Date of Flowering.
Abutilon	Cuttings	Early spring ..	6in. ..	All summer.
Anthericum variegatum ..	Roots and seeds ..	When ripe ..	4-6in. ..	Orn. foliage.
Aralia Sieboldii (Fatsia japonica)	Cuttings of ripe wood	Autumn and spring	5in. ..	Orn. foliage.
Araucaria excelsa	Seeds and cuttings	Spring under glass	4-6in. ..	Orn. foliage.
Aranis Lily	Division	Summer	4-12in. ..	August-Easter.
Aspidistra lurida	Division	Spring	Various	Orn. foliage.
Azaleas (In lian)	Cuttings	Early summer ..	4-12in. ..	Autumn to spring.
Balsams	Seeds	March-April ..	6in. ..	August.

CORRESPONDENCE

“SURPRISES?”

THE flowering of the New Zealand Flax (*Phormium tenax*) and of the *Dracæna* or *Cordyline* is not confined to the Southern Counties, for there are many plants of both these well known New Zealand natives flowering abundantly at Scarborough and other Northern stations. The wonder is that they are worth mention at all, as each year they flower freely, if not quite so abundantly as this year! By the seaside these should be planted in any public garden where there is room for them to develop. Never in the course of many years have I seen the *Phormium* cut severely, and the *Cordyline* has perhaps been cut down to the ground once in twenty years, so they may be depended upon to vary the vegetation during winter. *Aralia Sieboldi* is another shrub that is often miscalled tender, while it stands cold and wind by the sea as robustly as the Japanese *Euonymus*, the only difference being that the *Euonymus* prefers the open air and sunshine while the *Aralia* prefers being in shade under trees or under a north wall. One of the plants that shows the effects of last year's heat and sunshine is the Cape Agapanthus. In the North this does not flower freely every season. This year I counted twenty-one heads of bloom in various stages on one clump that had been divided and the crowns separated the year before last, a record worth mention. How excessively vigorous the spikes of *Gladiolus primulinus* are this wet season! If they ripen their bulbs sufficiently after this cold and wet season this charming bulb will take its place as one of the indispensables in the hardy border. The hybrids one is tempted to think must be less impervious to wet than the spray-loving *Gladiolus primulinus* (from the Zambesi Falls), but there is always room for a surprise in the behaviour of hybrids. Surprises, whether they be pleasant or unpleasant, are the soul of gardening for pleasure and stimulate to still greater adventures. How dull it would be if there were no difficulties to overcome; there would be no successes to chronicle! The next great surprise that I am looking forward to is the flowering of the Blue *Laburnum* found in Australia. I do not know that it will be hardy in England, but I have seen young plants that are exactly like young seedling plants of the ordinary *Laburnum*, and as far as looks go they should require the same conditions. I only hope that when they flower it will be later in the season, as I do not think the two plants would look well together. As in the case of the Japanese *Wistaria*, it is a pleasure to have a succession of flower, be it early or be it late.—E. H. W.

WHY “AMETHYSTINE”?

WITH reference to “G. J.’s” query on page 418, I have a plant of *Eryngium* the specific name of which is *amethystinum*, but the colour of the whole plant is *steely blue!* In Johnson’s Dictionary the amethyst is described as of a violet colour. I suggest that in nurserymen’s catalogues the epithet “amethystine” has an attractive sound to purchasers, certainly more so than the “reddish purple” which your correspondent considers to be the colour of the amethyst.—M. J. T.

THE LOQUAT FRUITING OUTDOORS.

I AM sending branches of Loquat or Japanese Quince (*Photinia japonica*), bearing ripe fruit. I thought it might interest you to know that the tree from which the branches were taken is laden with ripe fruits. It is growing in the open border

in the gardens of Elfordleigh, Plympton, South Devon. The tree is about 20ft. in height and as much through. It was raised from seed sown about thirty years ago and is quite unprotected by any wall or screen. It has flowered on several occasions, but this is the first time we have gathered any ripe fruit from it.

It very rarely fruits in this country, the blossoming period being so late in the year. It is a very handsome tree or shrub and is well worth growing for its foliage alone. Sufficiently hardy to withstand the cold of an ordinary winter; an unusually severe frost is likely to prove fatal to it. For this reason it is usually given the protection of a wall. It prefers a rather light loamy soil and does not really succeed in very stiff loams.—F. W. RICH, *Plympton, South Devon.*

[The fruits sent were fully ripe and quite pleasant eating. They have a brisk acid flavour which would make them especially welcome in hot weather. They are usually considered more suitable for culinary purposes than for dessert however. A large proportion of the interior of the fruit is taken up by the seeds which, three in number and $\frac{1}{2}$ in. long and wide, remind one, though much smaller, of those of the Horse Chestnut. They have the deep brown of the dried “cobbler,” however, rather than the glossy red-brown of the freshly-opened Horse Chestnut seed. Like so many other edible fruits the Loquat belongs to the great Rose family.—ED.]

DWARF POLYANTHA ROSES.

IN that able and informing article on the above by “White Lady” on page 369 no mention is made of Laxton’s *Crimson Orleans*, a sport from the well known *Rose Pink Orleans*. Probably the writer has not tried *Crimson Orleans*; it is, however, a good thing! The individual flowers are not too closely packed on the spray, a feature that enables the blooms to open freely, while the foliage would appear to be practically immune from attack by mildew. Its colour is fittingly described as brilliant crimson. We have here a dozen plants of it. “White Lady” rightly emphasises the fitness of beds on a lawn for accommodating these “Poly-Poms.” In addition to this position these dwarf *Roses* look well used as a grouping in the front-make-up of a herbaceous border, especially an open corner site. Furthermore, the low trim habit of

the dwarf *Polyanthas* renders them particularly suitable as permanent plants in flagged and other strictly formal gardens. Incidentally, too, where there is much bedding-out to be done annually and labour and other means are none too plentiful,

FRUITS OF THE LOQUAT, *PHOTINIA JAPONICA*.

it spells economy in the long run to include a few beds of these multiflora dwarfs in the bedding scheme because they ask so little attention year after year.—C. T., *Amphill.*

A GRAND PERENNIAL.

LAVATERA OLBIA is one of the most useful and reliable plants for late summer blooming. Here, it usually opens its first flowers about mid-July, from which time a continuous succession is maintained until the late autumn. Individually, the flowers are about as large as those of a good *Hollyhock*, single and of a lively pink, veined with rose. The leaves, bluntly lobed, are a dull green and so thickly covered with fine hairs that the plant is afforded a grey effect. Though *L. Olbia* never sets seed here, it is easily propagated by cuttings, and these grow away so quickly that they will bloom in their first season. *L. Olbia* is a robust and long-lived plant, and one that will thrive in poor, hot soil without any attention

A USEFUL PLANT FOR LATE SUMMER FLOWERING, *LAVATERA OLBIA*.

beyond cutting back to the base every spring. It appears to be perfectly hardy, and is quite indifferent to drought, even in our thin, shaley ground. The specimen illustrated is over ten years old, and as vigorous and floriferous to day as ever it was. It is more than 4ft. in height and fully 6ft. in diameter.—A. T. JONSON, *North Wales*.

THE BRUGMANSIA OUTDOORS.

I SEND you a picture of *Datura* (*Brugmansia*) *Knightsii*, a native of Africa, growing in the open in the "white garden" of the Rookery, Streatham Common. The stems have been pruned at a height of from 5ft. to 7ft. in order to facilitate removal and transport to Battersea, where they are kept under shelter during the winter. The large white trumpet-shaped flowers (double) here attain a length of about 10ins., but at Kew, where the plant is grown under glass and not cut down, the flowers are larger.—H. C. WARD.

THE DOUBLE SUN ROSES.

WHETHER or not we prefer double to single flowers is a question which we would require to consider well before making a general pronouncement regarding it. In the case of the Sun Roses it would be difficult to answer from a purely gardening standpoint. The single flowers are charming indeed, and no lover of the *Helianthemum* would willingly say anything which would appear to be derogatory to their loveliness. But for many places they have the defect of being so fugacious that in bright weather and when the day is blowy the flowers are sometimes past before midday, and in dull weather the little bushes are covered with buds which rarely open on many days in summer. On the other hand, the double varieties retain their petals much longer and are independent of sunshine once they have opened. These, briefly stated, are the main factors which should decide the choice of the one who seeks to add some of these flowers to his or her garden.

But there is another point to be considered, and one which is a strong argument against most of the double varieties in existence. This is that the flower-stalks are not strong enough to support the blooms erect and, in consequence, they hang down in a manner which prevents them from shewing properly except in places above the level of the eye. This has always been the great obstacle in the way of the majority of the existing double varieties of *Helianthemum*. Of these there are many which may be enumerated, although one must promise that the nurserymen appear to name these to suit themselves in many cases. Among those offered are *album plenum*, white; *Double Chocolate*, chocolate brown; *hyssopifolium multiplex*, orange; *Salmon Queen*; and *Serpyllum plenum*, yellow.

The most valuable of all, however, are the double varieties which have originated from the old *H. amabile* or *H. venustum*. The oldest of these is *H. amabile fl. pl.* or *venustum plenum*, which, from being praised by Mrs. C. W. Earle in one of her works—"Pat-Poutin from a Surrey

Garden"—came into considerable prominence and, from want of another name, was called "Mrs. Earle." This, with the varieties derived from it, must be greatly favoured by all who have grown them. They have not the falling of the other double varieties, and hold their flowers well up and are not only floriferous at the same time as the others but give a few flowers long afterwards, sometimes until frost has set in. The first sport of this fine variety, which has rich crimson flowers, was the bright yellow *Jubilee*, raised at Aberdour by the late Mr. P. Hill-Normand. This was followed by a bronze variety called

BRUGMANSIA KNIGHTII FLOWERING OUTDOORS IN LONDON.

Bronze Jubilee, originating in the same garden. Still another double variety has originated with Messrs. Stormonth at Kirkbride, Cumberland. This is *Cumberland Belle*. It gives plants which bear crimson, bronze and yellow flowers on the same bush. All these double Sun Roses are as easy to cultivate in light soil and a sunny place as any others, and by their beauty lend much assistance to the attractions of the rock garden.—S. ARNOTT.

THE GIANT IRIS OCHROLEUCA.

THAT is a very charming illustration in *The Garden*, August 12, page 394, of *Iris ochroleuca*, and I can confirm the reference to it liking damp soil, wherein it often reaches a height of 6ft. I have grown it for many years now and consider it one

of the most attractive Irises for a border. It is a most accommodating plant, too, revelling in the partial shade found under a pergola, where the blossoms unfold gradually and continue longer. At the same time I have been most successful with it on a south border, open to every gleam of sun, and during the early part of July had a larger show of flowers than ever before. Probably the hot summer of 1921 and ripening had a deal to do with the abnormal number of flowering spikes. *I. ochroleuca* differs from some of the flags from the fact that its foliage is slender and sword-like. As is known the blossoms are borne one above the other, earning for it, in some quarters, the not inappropriate name of "Pocket Iris." I counted no fewer than five flowers out simultaneously on several spikes this year.

To me it seems somewhat singular that, although an old Iris, it has never become common, indeed, in many gardens where Irises are grown, *ochroleuca* is not always found. I am glad that the writer of the very interesting article points to the advisability of planting at this season of the year. Those who omit to do so until spring often miss a season of bloom; at any rate, this is true of *I. ochroleuca* so far as my own experience goes.—W. LINDERS LEA.

TROPEOLUM SPECIOSUM.

IS there to be found a more vivid-coloured flowering creeper, when once established and doing well, than *Tropeolum speciosum*, or one about which there has been more disappointment at the unsuccessful attempts at cultivation? I venture to say there is not. The reference to it, as having been raised from seed by H. C. W. (see page 395) in East Surrey, gives one hope that the general experience of failure in southern counties may yet be overcome. It is certainly a capricious plant and difficult to understand. I have seen it thriving in Devonshire in isolated places, but if one wishes to see it in its rich prodigality of emerald green foliage and brilliant vermilion blossoms, one may do so north of the Tweed, for around many a Scottish homestead *Tropeolum speciosum* is to be found in richest garb. It is certainly a moisture loving plant, as one finds it running over limestone rocks where water trickles, and in the Highlands, amid peat bogs. The tantalising part of it is, that you plant your specimens or sow seeds and they grow for a time, in the mortar rubble and loam

you have prepared, and then die off. You wonder then whether the cool environment of Scottish moors does not count for much!—CLAREMONT.

THE MOUNT ETNA LILY.

THIS is a little-known name for what will perhaps be more familiar as *Sternbergia lutea*, a very valuable late autumn Crocus-like flower that—planted in a position to its liking—never fails to produce its golden yellow flowers in abundance in late autumn. Plant in a warm, sheltered position in light sandy soil. The bulbs hate disturbance and, in cold and exposed places, should be given slight protection after the flowers are over until spring. Never touch the bulbs until they become too crowded, then lift immediately flowering is completed, divide and replant.—BULBIST.

GARDENING OF THE WEEK

FOR SOUTHERN GARDENS.

The Kitchen Garden.

Cardoon.—As this plant becomes fit for blanching it will be necessary to remove some of the bottom leaves and to ascertain that the roots are sufficiently moist before carrying out the operation. The remaining leaves must then be drawn closely together and made secure by strong raffia, afterwards placing bands of brown paper and hay bands round the base of the plant, gradually adding to such until the whole of the plant has been dealt with.

Lamb's Lettuce, or Corn Salad as it is frequently called, makes an additional autumn and winter salading. The seed may be sown now in drills similarly to Lettuce, but it is not necessary to thin out so severely. This plant is very hardy as a rule, and will generally continue to throw up a goodly amount of leaves throughout the winter.

Cauliflowers.—To secure good heads of early Cauliflowers next spring it will be necessary to sow seed now, and a further pinch may be added in a fortnight's time. Sow thinly in a warm, well drained spot outside or, as some growers prefer, in boxes. As soon as the plants are large enough prick out, about 4ins. apart, into frames where plenty of air can be given and dampness guarded against. In addition to those in the frames pot a quantity into 4in. pots and place them in a brick pit so that plenty of light and air may reach them. Plants grown in the latter way should make excellent stuff for potting into larger pots early next year to provide the first cutting.

General Work.—Should such be required make further sowings of Prickly Spinach as ground becomes vacant. Examine the rows of late Peas, and if mildew has made its appearance dust the rows with sulphur to help check the fungus. The month of July was so wet that watering should not be required for late Peas. See that late-sown roots are sufficiently thinned in good time. Watch the supply of Lettuce seedlings and, if necessary, sow more seed thinly on a warm border.

The Flower Garden.

Grass Seeds may be sown now and onwards for several weeks or, if preferred, postponed until next spring. If sowing to make a tennis or croquet ground, see that the site is well prepared and the best seed used for the purpose. After getting the surface to a fine and perfectly even finish, scatter the seeds liberally, afterwards raking and rolling them in unless the condition of the soil is such that the latter operation had better be postponed for a few days.

Hardy Annuals.—To provide an early display next season it is a good practice to sow seeds during the present month. Circumstances will probably settle where and how it must be done. It is possible to sow directly into their flowering quarters unless the site is greatly exposed and the soil cold and retentive, in which case the seeds should be sown on a warmer site and the young plants lifted and placed in their permanent positions as early as possible next year. Annuals such as Larkspurs, treated thus, make strong plants and give a splendid display.

Hardy Fuchsias.—These graceful and free-flowering plants are most useful for brightening up beds and borders as the season advances. In favoured localities a plant will soon develop into a large bush, and a few such bushes suitably placed make an excellent lawn group. After flowering, the young growths arising from the base afford a ready means of increase if inserted as cuttings.

The Hardy Fruit Garden.

Planting Fruit Trees.—Should this work be contemplated on a large scale and the site has to be cleared the matter may well receive early attention, so that the plan may be carefully thought out and the different varieties allotted to their respective positions. Having arranged this the order may, with advantage, be placed at an early date in the nurserymen's hands, as this may lessen the possibility of having to accept substitutes.

Fruit Under Glass.

Early Vine Border.—If the Vines in the early house have failed to give satisfaction, the reason, in all probability, is faulty root action. To correct this it may be necessary wholly or partially to remake the border according to conditions ascer-

tained upon inspection. Should there be both an inside and outside border, it will be unwise to interfere with both of them in one season. Deal with the inside one first and encourage as far as possible the making of abundant roots inside, as they are here under control. Having accomplished that it may be found possible after a couple of seasons to do away with the outside border. If this cannot be done without destroying strong roots, try to reduce it as much as possible, for outside borders are more of a handicap than a help in growing early Grapes. The compost required for Grape culture is good fibrous loam to which may be added some crushed bones, wood-ash and rubble. The drainage must be ample and clear, and overlaid with freshly cut turves placed grass downwards.

H. TURNER

(Gardener to the Duke of Northumberland),

Albury Park Gardens, Guildford.

FOR NORTHERN GARDENS.

The Kitchen Garden.

Cabbages for Spring Cutting.—The ground should now be prepared for the reception of plants from the first sowing. This crop is generally found to do well on ground from which early Potatoes have been cleared. The soil should be fairly rich, but not enough so as to cause soft growth before severe weather sets in. Always aim at having firm, sturdy growth. Where such varieties as Flower of Spring or Harbinger are grown, 18ins. between the rows will be ample, allowing about 12ins. apart in the row.

Vegetable Marrows.—Owing to the erratic season Marrows in the open are much later than usual in swelling their fruits. Liquid manure should be given frequently to assist plants which are bearing heavy crops. Cut the fruits before they attain too large a size and remove all superfluous or decaying foliage.

Onions.—Look over planted-out Onions and bend over the stems to one side so that the bulbs may be induced to swell to their fullest extent and quicken the maturation of the crop.

General Work.—Continuous rains have opposed the use of the Dutch hoe in the destruction of weeds, but every favourable opportunity should now be taken to have the ground hoed and cleaned. All spent crops should also be cleared away, burning all pea and potato banlms.

The Hardy Fruit Garden.

Gathering Fruit.—The principal work in the hardy fruit department at this time is the protecting of crops from the ravages of birds and the harvesting of those which are fit for gathering. Early Apples will require to be looked over frequently, and any that are ripe should be picked and stored for early use.

Raspberries.—Cut out the old fruiting canes immediately the crop is cleared, and thus allow the sun and air to circulate freely among the young canes. The latter should be secured to stakes or trellis if there is any likelihood of them being damaged by wind.

Strawberries.—Lift the remainder of the runners required for spring planting and heel firmly into lines in the nursery border, afterwards cleaning between the rows of the old plantation. A good dressing of short litter may then be given for pointing in at a later date.

The Fruit Room.—Take the opportunity during inclement weather to have this structure thoroughly cleaned so that it will be ready for the reception of the various fruits that require storing. Wash down the shelves and linewash the walls. So long as the shelves are clean nothing else is required on which to lay the fruit.

The Flower Garden.

Trimming Hedges.—The various types of hedges bordering the flower garden may now receive their final trim of the season. Opinions differ regarding the shape to which hedges ought to be trimmed. Personally, I think the wedge-shaped top is the neatest, and is less liable to sustain damage from heavy falls of snow than the broad-topped form. Young hedges should be cut well down so that close growth may result.

Propagating Bedding Plants.—Time must now be found for carrying out this important work, as every day brings the danger of severe

frosts nearer. Violas, Pansies, Calceolarias, Pentstemons, Antirrhinums, Nepeta and any other bedding plants amenable to cold frame treatment should now be got in. Lavender will also root readily at this time.

JAMES McGRAY.

(Gardener to Sir Henry H. Hoildsworth, Bart.),
Coodham, Kilmarnock.

GREENHOUSE AND CONSERVATORY.

Achimenes as they pass out of flower should be stood in cold frames, gradually withholding water as the foliage dies down. The frame lights should be kept on to keep the plants dry. When the stems have dried up the plants should be turned out of their pots and the rhizomes stored in dry sand for the winter. Small tins are very suitable for this purpose, but it is advisable to punch a few holes in them as this allows any superfluous moisture to escape.

Veltheimia viridifolia and *V. glauca* are natives of South Africa, and deserve to be more generally cultivated for the cool greenhouse. They are not very showy plants, but have a quaint charm that appeals to many plant lovers who are fond of interesting plants. In common with so many South African bulbous plants, their growing season is during our winter, and dry roots should be potted up at this time. Plants that have been resting in cold frames are now showing signs of growth, and should be shaken out and repotted, cleaning away all dead roots and decaying matter from the base of the bulbs. These plants grow well in any good potting compost, using 5in. or 6in. pots, according to the size of the bulbs. After repotting they may be stood in a cold frame or cool greenhouse, giving them very little water until they have made some growth and a quantity of new roots. The repotting of bulbous and tuberous-rooted plants is usually the most critical stage, as more plants of this class are ruined at this time through over-watering than by any other cause. As there is not any root action, an overdose of water renders the soil sour and stagnant, and the fleshy roots of most bulbous plants refuse to grow in such a medium.

Nerines require attention at this time. Some of them, such as *N. Fothergillii* major, should now begin to throw up their flower-spikes and soon afterwards signs of fresh growth. They usually flower best when the pots are crowded with bulbs, and repotting should only be done at an interval of several years. Some cultivators believe in repotting the plants after they have finished flowering, while others prefer to repot before they flower and start into growth. If they are simply to be shifted into a larger pot without disturbing the roots, repotting may very well be done when they have finished flowering. If the plants have to be divided or have to be repotted through being in bad condition at the root, I prefer to repot them before they start into growth, as it gives opportunity to clean off all dead roots and decaying matter at the base of the bulbs. If dry bulbs are purchased, they, of course, are best potted at this time. Nerines require a rich compost, as they are not frequently repotted. A good rich mellow loam should be used to which a little leaf-soil and some dried cow dung has been added, also a 6in. potful of fine bone-meal to every bushel of soil. Bone-meal is very beneficial on account of its lasting properties, and is the best manure to use in the potting compost. Enough coarse clean sand or old mortar rubble should be added to render the whole porous. *N. Fothergillii* major has large bulbs, and when doing well makes fine specimens, thus when repotting five or six bulbs may be put in a 7in. pot. The smaller varieties may be potted singly into 60-sized pots, or three or four in 48-sized pots. After potting they may be stood in a cold frame or on a shelf in a cool greenhouse, giving water very sparingly until they have made plenty of new roots. Grow quite cool, with full exposure to sun and air at all times.

Calceolarias should now be in 60-sized pots and placed close to the glass, so as to obtain a dwarf habit. A temperature of 45° to 55° will suit these plants admirably. Pot on the plants as it becomes necessary.

Anemones.—The roots of the tuberous varieties may be potted up from now until the end of the year, so as to ensure a succession of flowers. As pot plants these Anemones are ideal, not only on account of their flowers, but also for their distinctive foliage. Attention is essential as regards watering.

Royal Botanic Gardens, Kew.

J. COULTS.

PLANTS FOR A SMALL MORaine GARDEN

(continued from page 401.)

INULA ACAULIS.—An interesting "Fleabane," with large yellow flowers thrown out very little above the ground level. Might be useful as a later flowering plant.

Sedum luxifolium.—A useful evergreen shrub about 6 ins. high, with whitish flowers in the early summer, which is placed in a central position on one of the sections.

Laurentia tenella has tiny bright green rosettes, from which arise, on short stems, pretty, delicate, obelia-like whitish flowers. This plant has come through four winters in an exposed position, but is not increasing, and it is possible that a specially bad winter may finish it off; it would probably be more at home in a damper position, but away from the moraine there would be the great risk of it being overgrown by more vigorous plants.

The **Lewisia**s are a great acquisition and mostly have lovely flowers and rosettes; it is perhaps unfortunate that they come into flower at the same time as many of the Aizoön Saxifragæ. Four species were planted in 1918; of these, **Lewisia Cotyledon** with its large leathery-leaved rosettes and lovely buff flowers with deeper rose suffused markings along the centre of each petal, and **L. Howelli** with its large deep green crinkled edged rosettes and pale apricot coloured clusters of flowers with rosy flushed stripe the lengthway of the petals, are the only plants that have flowered with me up to the present; both have flowered annually during May, providing large clusters of flowers each year, but they have failed to open seed and have shown no sign of throwing out further rosettes. **Lewisia Leeana** and **L. oppositifolia**, the other two species as yet have not flowered, nor shew any signs of increasing, although both appear to be quite healthy.

The **Micromeria** family provide one or two dwarf, sweetly scented "shrubbets," very suitable, especially, for the outer edges or crevices, the two best that I have tried being **M. corsica**, with deep green scented foliage on stiff, wiry stems, thrown out horizontally about 3 ins. high; from these pretty rose coloured flowers spring up in the late summer. One plant, unfortunately, has attracted the attentions of the "cat" family, which in the spring seems to lay on it, to the detriment both of the **Micromeria** and some adjacent plants, one of which happened to be the interesting very dwarf, silvery-leaved **Raoulia australis**. When it is noticed that the plant is being visited now, a few pieces of broken glass are placed about the plant for a day or two to discourage the unwelcome visitors. Another good species is a golden-leaved one which was noticed in the Edinburgh Botanic Gardens under the name of **Micromeria varia**. It was sent me originally as **Thymus "Golden Dwarf"**; it is specially good for a crevice on the outer edge, making a compact and dwarf delicately scented bush. All this family are easily propagated from shippings.

Oxalis enneaphylla and **O. e. rosea**, pretty both in foliage and flower, usually flower well and are much more compact on moraine than in richer conditions, which induce longer and weaker stems in place of the almost stemless flowers produced on moraine. This plant never seems to ripen its seed. **O. adenophylla** is another lovely plant which, on moraine, produces large almost stemless flowers in clusters, but the bulbous root seems to have a tendency to rot off after flowering. In shade and richer soil the pretty grey foliage and rosy flowers are much less

compact, but it flowers well and the flowers last much longer. The flowers in the more exposed positions are over very quickly in the hot and dry sunny weather that usually happens at the period it is in flower. Sun is requisite for the flowers to open out. The root of **O. adenophylla** is very different to the "corms" of **O. enneaphylla**, being more like that of a Cyclamen. I discovered this when trying to get some out for a friend, and also that it had worked its way down a good depth below the ground level.

Pentstemon cristatus, a fine dwarf, prostrate shrubby plant with its dark evergreen foliage and quite pleasing purplish blue flowers, as is also **P. Davidsoni**, which is more prostrate, if anything, with pretty grey green leaves and lovely red flowers. These are perhaps more suitable for a dwarf wall, but are certainly worthy of a choice position.

Phyteuma comosum.—This is the only **Phyteuma** that has been tried. It was planted in 1916. The dark green campanula-like leaves on the plant which never shewed any sign of increase or flower made me doubtful as to whether it was the correct plant. However, this summer, probably due to last year's "scorching," having put new life into it, resulted in it producing this last June its interesting quaint blue clustered heads of bottle-shaped (Schweppe's soda water contracted to a pint) flowers.

Potentilla nitida.—This, the best of the species with silvery grey leaves and fairly compact mats, would be indispensable, with its extremely pretty rosy pink flowers, if it would only produce the flowers more freely. It has been tried on and off the moraine, in good and very poor soil, but with little success so far as flowering goes, the plants never bearing more than three or four flowers. The white-flowered variety seems, however, to flower more freely but is not so beautiful as the type.

Saponaria caespitosa is the loveliest of an interesting family that has several suitable varieties. It is quite dwarf and fairly compact with its somewhat fleshy, narrow-pointed leaves and lovely good-sized rosy pink flowers. The fleshy leaves, unfortunately, are an irresistible attraction to the slug family, and only persistent watching, especially in the winter, can save the plant when slugs are about. Owing to this one or two of the plants have been covered with glass during the past winter, which kept the leaves dry, and the slugs certainly did not seem to trouble them so much. **Saponaria Boissieri** is a more compact plant with good-sized flowers of a paler pink. **S. Wienmanniana**, a hybrid raised by Sundermann, seems to be more compact than the last with very similar flowers more freely produced. **S. Sundermannii**, compact, but somewhat larger, with white flowers that seem to go pink, has longer stems than the above and not nearly so freely produced. The plant that I have under the name of **S. pedumiana** is very unlike the other **Saponarias** (and possibly may not be correct). It has bright grassy green tufted foliage fairly compact, from which are produced pretty alpestris-like (not scalloped) white flowers on 4 in. to 6 in. stems. **S. Wilkommiana** is more in the way of a compact **S. ocymoides**. It always produces quite a lot of clustered pendulous flower-heads, but they have always failed to open out, and it is difficult to understand the reason. I thought that they might be aborted by frost, but this year, when so far as I know there was no night frost about at the time, they have just acted the same way.

Among the **Sedums** two striking species from the Caucasus add to the interest and are quite suitable. Although biennial, they are easily raised from seed and well worth a little trouble. Both species, **S. pilosum** and **S. sempervivoides**, have sempervivum-like rosettes, the former having bright green hairy rosettes which are covered with pretty pink flowers in early June. **S. sempervivoides** has glaucous green, stiff, almost echeveria-like reddish tinged rosettes which grow up in the Sempervivum manner before opening out their dazzling scarlet flowers.

T. ASHTON LOFTHOUSE.

Seasonable Work Among Chrysanthemums

To obtain a full harvest of blossom the plants will need daily, almost hourly, attention in the case of those grown specially for large blooms.

THE buds are now swelling up freely on plants of very fair strength, clean and free from mildew. They are, altogether, very interesting objects to the enthusiast. The beginner may think it is a very simple matter to place plants under glass; it is much easier to do so in these days of comparatively dwarf plants to what it was when they often attained a height of 6 ft. and more.

But that is not my main point. It is rather that of placing plants in houses so that the blooms will be at their best just when required—late, medium and early-flowering sorts. When the cap is broken and the colour of the petals can be seen, moisture must not reach them. It would be a mistake to leave them out after this stage. The best structure is a cool one, dry and facing north, preferably, for the earliest varieties, including the singles.

Then there are a few that need a long time to develop their flowers, such as Mrs. R. C. Pulling, Victory, Majestic and Louisa Pickett. The latter, I think, requires eight weeks from the date of housing if the buds are then the size of a farthing, the others seven weeks; the medium early ones six weeks and the naturally early varieties a month to five weeks from the time that the colour of the petals can be seen.

TREATMENT UNDER GLASS.

Avoid overcrowding; have the buds, if convenient, about 4 ft. from the roof-glass; leave open, for several days, doors and ventilators. Fumigate several times to kill green and black aphides before the pests get among the unfolding flower petals. Do not sprinkle tobacco powder on any unfolding buds, else, in time, the powder may absorb moisture at the base of the petals and thus rot the whole bloom. Use dry sulphur freely if mildew covers the leaves.

As the flowers unfold lessen the ventilation considerably; continue to feed, but with weaker doses each week. Put a shade on the roof-glass, and allow the blooms to develop in a quite cool, dry structure. Do not use any nitrate of soda nor sulphate of ammonia; there will be sufficient stimulant in prepared artificials.

Examine the buds for earwigs every night, and for caterpillars and leaf-rolling grubs during the daytime, the latter pests are numerous this year.

Specimen plants should be placed by themselves to enable them to retain their leaves whole and green. Turn round such plants two or three times in a week towards the best light.

Decorative stock must be freely fed, disbudded and staked. Provide retarding shelters against north walls or fences. G.

SHREWSBURY FLORAL FETE

OF the good things seen at Shrewsbury recently, Roses, Sweet Peas and Carnations stood out among the flowers, and the herbaceous plants were well worth a visit to see for those making a garden, while the endless variety of fruits in season was superb.

Roses were shown more extensively than any other flower, and it would be a big task to chronicle the whole of the exhibits. Those from Messrs. Gunn, Olton, however, won the champion competitive prize with a very remarkable lot arranged in tall pillars 12ft. to 15ft. high. Other fine lots came from Messrs. Mattock, Oxtord and Dunton, Wolverhampton; while non-competitive exhibits of Messrs. Dobbie, Edinburgh; King's Acre Nurseries, Hereford; and Messrs. Alex. Dickson and Co. stood out among many others.

Unlike the London shows, the prize money offered induces many private gardeners to come forward, and the decorated fruit tables were a sight to enthuse over. Mr. James Vert, gardener to Lord Howard de Walden, secured first prize for a table resplendent with such good things as Peach Peregrine, Nectarines (of which Pine Apple was the best), Apricot Moor Park, Plum Transparent, Melons and several varieties of Grapes. The second prize went to Sir John Leigh's gardener, whose exhibit was but a few points behind the winner of the first prize. Winners in the Grape classes were Mr. R. J. Corbett, Messrs. Webber and Sons (Minehead) and Lieutenant-Colonel Leigh (gardener, Mr. A. J. Cook).

Among non-competitive exhibits of fruit a large group by The King's Acre Nurseries, Limited, was remarkable. Apple Herring's Pippin was very conspicuous. James Grieve, as ever, was one of the best Apples. Pears Beurre Supertin, Margaret Marrilat and Doyenné du Comice were all well shown, as were Nectarines, Peaches and Plums. A gold medal was the well merited award.

The Worcesterberry, a hybrid fruit of interest, and some good dishes of Apples were shown by Mr. E. J. Parsons of Worcester.

Vegetables from the Hon. Vicary Gibbs (gardener, Mr. E. Beckett) included Peas such as Quite Content, Tomato Peachblow (a rosy red), Potato Drummond Castle and Runner Bean Prizewinner. Gold medals to groups such as these and those of Messrs. Sutton and Sons, Dickson and Robinson are fitting comments on their quality and style of arrangement.

Carnations were well shown by Messrs. C. Euglemann (who secured the challenge cup), C. Wall, Jones and Son, and Stuart Low and Co. Gold medals were awarded to these groups.

Sweet Peas, as might be expected, were very fine. Most of the best came from trade exhibitors, of which Messrs. Alex. Dickson, Newtownards; Herd Brothers, Penrith; R. Bolton, Halstead (who secured gold medals); and J. King and Sons, Coggeshall. The varieties are legion, but Picture was one of the best in pale rose colour.

Messrs. James Cypher and Sons, Cheltenham, staged a large group of plants. Here were *Statice profusa*, Orchids, *Ixoras*, *Crotons*, *Dracenas*, *Francoa ramosa* and such plants. This group was backed with stately Palms.

Little behind and similar groups came from Sir G. Kenerick and Mr. W. R. Manning.

The hardy flowers from Messrs. G. Gibson, Leeming Bar, were particularly gorgeous, but in this class Messrs. Maurice Prichard, Christchurch, were first and Messrs. Harkness, Bedale,

second. *Delphiniums*, *Lupinus*, *Phloxes* and *Antirrhinums* were the principal plants shown.

The only *Violas* and *Dahlias* in the Show came from Mr. H. Clarke of Taunton. Dainty rock garden plants came from Messrs. Bowell and Skarratt, who also had some *Nymphæas*.

Astilbe Grimo, a deep rosy pink with thick, heavy spikes, was noticeable in the group of Messrs. Bakers, Wolverhampton, and *Romneya Coulteri* in the Chalk Hill Nurseries' collection.

Phloxes all the way from Hawick, Scotland, were shown by Mr. John Forbes.

In an important class for rock gardens of 500 sq. ft. a fine display by Mr. T. R. Hayes, Keswick, secured Lord Howard de Walden's Challenge Cup and £50; Mr. P. Gardener, Ilkley, winning the second prize of £30, and Messrs. Broadhead and Son, Thongsbridge, the third of £20.

Rare plants were less in evidence this year, but a choice lot of Orchids came from Messrs. Sander and Sons and Stuart Low and Co., gold medals being awarded to both groups.

PLANTS FOR WINTER SALADING

LIKE most things grown in a garden, it is necessary, in the case of salads, to have them just when required, to look ahead and make provision accordingly. Practically all the real growth of each plant is finished by the end of autumn, the only continued growth being that of a few kinds assisted by the aid of fire heat.

ENDIVE AND LETTUCE.—There are two distinct varieties of the former, broad-leaved Batavian and the moss-curl'd. The first named is favoured for winter use because it resists excessive moisture better than the other and it is also large, free-growing and excellent when nicely blanched. Strong seedlings should be planted out 9ins. apart each way, at this season, in a fairly rich, deeply dug soil, in as dry a part of the garden as possible. Sturdily grown plants will resist frosts very well; the blanching may be done in frames or houses, but I prefer to blanch them where growing by placing two roughly made frames on them, moving the frames so as to ensure a succession of tender hearts. Tying up the plants and then covering with empty, inverted flower pots will also answer our purpose.

Cultivators may have their favourite winter Lettuce; I recommend All the Year Round as the best for the purpose. In the South, and on dry borders in the Midlands and North Midlands, the plants will do well outside even when severe frosts occur. But where it is convenient make use of a frame, too, it does not matter how roughly constructed the frame is as long as it affords protection in time of frost or heavy rain. Where soils are of a heavy, retentive nature, I find it answers well to place glass lights on 6in. pots inverted. The sides and ends being open, the air passing under prevents damping.

In the northern counties seeds should be sown before the middle of August, but in the South the first week in September will be soon enough. If raised too early the plants are liable to "bolt" prematurely. A rich, firm soil, steady growth without any codling are the essentials to success.

THE TOMATO.—Only where plenty of fire-heat is available and suitable houses is it advisable to attempt to grow Tomatoes throughout the winter months. If it is decided to grow them, they should be raised so that, strong and short jointed, they will be ready for planting out, or better still, for final potting into 10in. pots by the second week in October. The treatment is similar to that for

summer grown plants, except that more space must be allowed between the plants and a somewhat drier atmosphere maintained. Grow only special winter fruiting sorts. In this structure an odd Cucumber plant may be grown and plenty of Mustard and Cress; the forcing of Rhubarb and the blanching of Chicory and Dandelion will be, too, an easy matter and tend to economy.

CHICORY OR CHRISTMAS SALAD may be blanched in a cellar, shed or unheated glass structure. The points to observe are strong crowns (strong roots), packing close together in fine soil, avoidance of stagnant moisture and absolute darkness.

SALAD ONIONS AND RADISHES.—Make a sowing of Salad Onions at once, also one of Radishes at the same time. The third week in September sow more Radishes and afterwards sow in January and February in a suitable house or a cold frame. Sow the Radish seed broadcast and thinly, the French Breakfast being the best. Do not thin out the Onion plants except as they are used.

SPINACH BEET will be useful. Plants from July and August sowings will yield nice succulent leaves for a long period; the plants should be 16ins. apart.

CELERY.—Reserve the latest raised plants for use in the winter salads. The necessary attention needed will be that to ensure good blanching and freedom from damp.

BEET must be lifted and carefully stored in sand in a cool, dry position before frosts come. G. G.

Erica stricta as a Hedge.—For an ornamental hedge there are few finer plants than the Corsican Heath (*E. stricta*), which will attain a height of 4ft. to 5ft. in good loam. The stiff, wiry branches, thickly furnished with leaves of a very pleasing shade of green, maintain a neat, upright habit, so that very little pruning is needed to keep the hedge within bounds. Indeed, a well grown line of this Heath is always orderly without being formal. *E. stricta* flowers in late summer, the shell pink blossoms appearing on the tips of the shoots, and it continues in bloom until nearly the end of the year when the faded flowers assume a warm, foxy red tint which is highly attractive throughout winter. Any good lime-free loam will suit this species. It is rather impatient of drought, but generally of quite easy culture. The best time to plant is late April or May.

The British Pteridological Society.—The twenty-seventh annual meeting of this Society was held on August 14, at Llanberis. Members attended from Co. Dublin, Manchester, Reading, Horsham, Woodford and Brondesbury. The President (Mr. W. B. Cranfield) presided, and nine certificates were awarded to meritorious varieties. A long discussion took place on the question of the altered nomenclature of Ferns as part of the general revision of this subject at the Vienna Conference. Some doubt was expressed whether the settlement as presented by Dr. G. C. Druce in the December Gazette would be a stable one, and eventually it was resolved that a Sub-Committee, consisting of the President and Dr. F. W. Stansfield, be appointed to confer with the Royal Horticultural Society and the Kew authorities in order that the Society should come into line with the leading scientific bodies on the question. Among the new members who joined the Society during the past year was the eminent French botanist, Prince Roland Bonaparte. The Society cordially invites all lovers of British Ferns to join. Particulars of membership and copies of the Gazette can be obtained from the Hon. Secretary, Mr. C. Henwood, 21, Clifton Road, London, W.9.

ANSWERS TO CORRESPONDENTS

QUESTIONS AND ANSWERS. All communications should be clearly and concisely written on one side of the paper only, and addressed to the Editor of THE GARDEN, 20, Tavistock Street, Covent Garden, London, W.C.2. When more than one query is sent, each should be on a separate piece of paper. Plants for naming should be clearly numbered and securely packed in damp grass or moss, not cotton-wool, and flowering shoots, where possible, should be sent. It is useless to send small scraps that are not characteristic of the plant.

FLOWER GARDEN.

GLADIOLI NOT FLOWERING (C. M.).—The latter part of May is rather late for planting Gladioli and this may explain the lack of flowers, though it is quite possible that flower spikes will appear a little later in the season than would have been the case had the corms been planted in March or early April. Our correspondent does not say what price was paid for the Gladioli. If they were very cheap—and a large number of cheap corms were on offer last spring—these could scarcely be expected to include a big proportion of flowering size. With bulbs, as with seeds, it is false economy to purchase at low prices. As the corms appear to have been properly planted and have been well looked after, they should flower next year if they are lifted, when the foliage has ripened, and stored in a frost-proof shed.

LAVATERA OLBIA (G. T. W., Yorkshire).—The easiest method of propagation is by seeds sown in gentle heat in the spring. Although *Lavatera Olbia* is a perennial, it is usually more satisfactory when grown as a biennial; that is, seeds should be sown each year and the plants discarded after they have flowered. *Lavatera rosea* is not a "good" name. *Lavatera trimestris rosea* is an annual which may easily be raised from seed, but care must be exercised in transplanting. We are not acquainted with a perennial form.

ROSE GARDEN.

DWARF POLYANTHA ROSES ("Pompon").—The variety *Baby Tausendschön* should meet our correspondent's requirements, being identical in colour with *Maman Turbat*, but less robust, yet very free flowering. The dwarf *Polyantha* or *Pompon* Roses may be hard pruned in spring with excellent results. *Coral Cluster* and *Phyllis* are also free-flowering pink Pompon Roses deserving of attention.

ROSE MARECHAL NIEL (N., Lyndhurst).—The hot weather of May and early June is responsible for the ripening of the new growths and the quick flowering of the plant. Obviously, as the young wood is producing flowers now, it must interfere with the blooming next spring. Probably when these are cut more young shoots may push up if the autumn weather is warm and otherwise favourable.

ROSES ATTACKED (J. S. C., Hants).—The best spray for the Roses will be Bordeaux mixture applied at intervals from May onwards. Liver of sulphur and other washes usually used are impotent against black spot of Roses. The *Cineraria* leaves may be sprayed with a nicotine wash.

ROSE CUTTINGS ("Crauford").—If the proper shoots are selected and rooted, these will become Rose bushes of precisely the same variety as their parents and will not revert to a Briar, *Manetti*, *rugosa*, *laxa*, or whatever stock was used for the original Rose bushes. It often happens with budded Roses, both standard and dwarfs, that there are on the stock dormant buds too small to be readily seen at the time they are "worked," and consequently they are not removed. In the course of time these tiny dormant buds develop, and if not detected and cut off grow away and dominate the scion. Such growths if made into cuttings and rooted would naturally be independent bushes of the stock, which, with dwarf Roses, is usually *Rosa Manetti*.

GREENHOUSE.

CRASSULA FOR IDENTIFICATION ("Maive Poppy").—The plant sent is *Crassula tetragona*, a South African plant that requires cool greenhouse treatment, a sandy soil, a moderate supply of water in summer and not much moisture in winter, but the soil should never be dust dry.

FRUIT GARDEN.

CRAB APPLE, APPLE AND PEAR TREES (J. E. A., E. Yorks.).—In different parts of the country the stems of fruit trees have split, bark deep, more or less this year owing to the dry weather experienced last year and the sudden swelling of the trunks this year; there is no need for alarm, as nature will right matters in due course. We suggest that our correspondent fastens Bamboo canes to the wires and trains the branches of the Apple tree to the canes. It seems a pity to disturb the roots again so soon unless growth is very strong. Evidently the bush Apple, planted three years ago, is growing in a very unsuitable soil and would be all the better for lifting and re-planting in a drier and richer medium. Canker causes the malformation and, in time, the death of branches. It would be necessary to see affected portions of the latter to determine whether it was canker or not. Surface mulch all the fruit trees immediately after replanting.

TREES AND SHRUBS.

PYRACANTHA COCCINEA AS A HEDGE (A. D. N., Glos.).—*Pyracantha coccinea* (syn. *Crataegus Pyracantha*) could well be used for the hedge, but unless the wire fence is already in position, this support is unnecessary, as when grown naturally this plant becomes a fairly dense bush. With the variety *Lalandei* it is often planted against a wall, but both are excellent shrubs for ordinary positions. To make a hedge fairly quickly the shrubs should be planted about 3ft. apart, but the exact distance must be governed by the size of the shrubs and the time that can be allowed for their growth.

PLANTING AND PRUNING A BEECH HEDGE (E. E. B., Surrey).—Being a deciduous plant, Beech may be planted at any time from November to the middle of March when the ground is in a suitable condition, November being the best time. Just the trimming of the young twigs with shears may be done at any time during the summer when required. Hard pruning should be done at the end of March. The Japanese *Wistaria* may be obtained from Messrs. Wallace, The Old Nurseries, Tisbury Wells, or Messrs. Gaultlett and Co., Limited, Japanese Nurseries, Chiddingfold, Surrey.

MISCELLANEOUS.

NON-POISONOUS FUMIGANT FOR THE GREENHOUSE ("Maive Poppy").—XL All Nicotine Fumigating Shreds is a perfectly safe fumigant to use and non-poisonous. The smell disappears within twelve hours if the house is freely ventilated the morning following fumigation. This fumigant is supplied by Mr. G. H. Richards, 234, Borough High Street, London, S.E.1.

BEES KILLED (G. K., Reading).—The nectar from the lime probably intoxicates the bees, which are then caught and eviscerated by tits, or possibly mice, if the mutilation occurs on the ground.

MANURING TENNIS LAWN (C. S. H., Febridge).—The soot and fine earth would answer very well, but the lime must not be applied at the same time. A peck of soot and two of lime per square rod applied, the former at the end of September and the latter in November, would be a right proportion to use with one barrow-load of fine soil per square rod. If rotten stable manure is procurable and it is rendered rather fine, apply this early in November, one barrow-load per square rod, and brush it in during the winter months. Next Spring, about April, put on 4ozs. per square yard of fine bone-meal and roll the lawn afterwards; next summer the latter ought to be in a very satisfactory condition.

MELONS UNSATISFACTORY (W. M.).—The seeds are not faulty. There may be evilworm in the roots; this worm is very tiny, but does a lot of harm to Melons and Cucumbers. Melons in frames should be grown on a hot-bed made up of sweet litter in March and the plants

should be strong and ready to plant out in April. The bed must be firm. The rooting medium should be loam of a heavy nature rather than of a light, without any manure added to it and, while in a medium dry state, made firm for the plants. Top-dress and feed when the fruits are swelling, but keep the soil near the stems as dry as possible. Plant the Melons on slight ridges of soil, not on the flat, for extra warmth. The frequent light surface mulches keeps roots active and the plants strong and healthy. Ventilate freely in fine weather do not syringe in dull.

NAMES OF PLANTS.—E. B.—*Quercus Ilex*, Holm Oak.—E. E. B.—*Alyssum argenteum*,—"Torquay."—*Potentilla fruticosa*.—H. J. B., Barnwood.—*Catalpa bignonioides*.—G. H. S.—*Thuya plicata*.

Vines and Peaches in the Same House.—

Although it is not advisable to plant Vines and Peaches in the same house, where there is ample accommodation for them in separate structures, it is a fact that they are grown together in hundreds of gardens. Cultivators, who have had no experience with the two kinds of fruits when associated as referred to, will find it a difficult matter to give them correct treatment. The greatest difficulty is encountered in the spring and early part of the summer before the time comes when air in abundance can be admitted. The Peach is regarded as the hardier of the two, and so some cultivators refrain from ventilating as freely as they should do during the autumn, as they fear they may do harm to the Vines. Even where Grapes are still on the Vines very free ventilation may be given while the air is dry outside, and in the evening more air should be admitted to play directly on the Peaches than on the Vines. In cold, damp weather admit air also, but in less quantity, and have the pipes nicely warmed at night. The result will be to create a buoyant atmosphere, which will be conducive to the well-being of the Grapes while not exciting the buds of the Peaches. Both the Vines and the Peach trees must have sufficient water. Their roots must at no time suffer through lack of water, and it is equally necessary to avoid having the soil in a sodden condition. When the Grapes are cut, the Vines, as well as the Peaches, will be benefited by exposure to quite cool treatment—thus giving them a complete rest.

BARR'S Beautiful New Seedling NERINES

The most beautiful and easiest grown of Autumn-flowering Bulbs for the Greenhouse.

For autumn decoration in the greenhouse few plants can compare with Nerines for their brilliant and attractive colours. The flowers, which are produced in umbels of 6 to 24 blooms, are borne on stout stems varying in height from 1 to 2 feet. In colour they range from *dark red, vivid crimson, cerise and scarlet to salmon, coral-rose, pink, blush and white*, many having a glistening lustre which in sunlight gives them the appearance of being dusted with gold or silver. They remain decorative for many weeks, and their beauty may be enjoyed in a sitting-room as well as the greenhouse, if the pots are kept in a sunny window.

PLANTS FOR ADORNING WALLS

IN no branch of gardening is there displayed so general a paucity of originality as in the adornment with vegetation of the walls of houses and other buildings. The country home must be very old and very beautiful if it will not fit better into the landscape with some clothing of vegetation for the walls. On the other hand, a house must indeed be an epitome of ugliness if it looks better entirely smothered in Irish Ivy or, indeed, in "Creepers" of any description. Irish Ivy is an exceedingly useful, if much abused, plant, but it is emphatically an unsuitable covering for any building with any beauty either of workmanship or material. Even where Ivy seems to be called for, there are many more beautiful species and varieties than the Irish, though for screening ugly fences and such like it has the supreme advantage of rapid growth. In the two pictures on the following page there is depicted the shelter on the bowling green at Gravetye Manor, a simple structure made beautiful by its covering of the large-leaved Ivy, *Hedera colchica* (*Rœgneriana*), of which the seemingly varnished, deep green cordate leaves are very handsome. Even our small-leaved English Ivy, which often plays such havoc among growing timber, is intrinsically more beautiful than the Irish. The golden Ivies are not, on the whole, so satisfactory as the silver variegated ones, which latter are often wonderfully effective on buildings of red brick. It is really no more difficult to keep Ivy in its place on a building than any other self-clinging plant, and very little more difficult than plants which provide no support themselves—though these latter, because they obviously need constant training, tend to prevent neglect. Ivy should never be planted against or allowed to encroach upon old buildings in which the mortar has perished, otherwise it is but too likely to force its way between the stones and, as its stems expand, destroy the fabric.

The following are desirable Ivies, but it is usually better to select

sorts at the nursery, taking due heed of what the nurseryman has to say as to habit, etc., since the nomenclature of Ivies in commerce is particularly muddled. Of green forms *deltoides*, *ovata* (very distinct oval foliage), *pedata* and *sagittifolia*, the above all varieties of the English Ivy, and *H. canariensis*, larger leaved and handsomer than the Irish Ivy, are all worthy; while good silver variegated sorts are *Cavendishii* and *albo marginata*.

Next to Irish Ivy the most commonly used

wall plant is almost certainly the self-clinging Virginia Creeper, *Vitis inconstans*, generally listed by nurserymen and named by gardeners as *Ampelopsis Veitchii*. This is an effective plant enough and really beautiful when "lit by autumn fires," but is even faster growing than the Ivy and is almost as effectual in concealing the texture and detail of a building, so that it should be planted circumspectly and subjected to constant supervision. It must always be borne in mind

that this fast-growing plant is very apt to die completely away from no obvious cause, and that the bunches of "suckers" adhere so firmly to the fabric that it is impossible to remove them. On buildings with offensively glazed "facing-brick" fronts this peculiarity may be an advantage, but it is grievous on beautiful stonework.

The larger-leaved Virginia Creepers, though needing periodical attention, are really far more suitable for house walls, since their thinner habit of growth not only prevents their entirely obscuring the wall, but allows the beauty of their foliage to be better appreciated. *Vitis quinquefolia*, the true Virginia Creeper, is provided with suckers by which to attach itself to the object upon which it is climbing, and is, on that account, desirable; but it is not easy to procure true, the plant usually supplied under this name being *V. vitacea*, which is not self-supporting on a wall, but has larger leaves, brighter in colour both when in growth and when, in autumn they turn crimson before the fall. *Vitis heterophylla* is excellent against a south wall, especially if it has a rather restricted root-run, as its porcelain-blue berries are then very freely produced.

Of climbing trees suitable for house fronts, surely there is none more beautiful than the *Wistarias*, which, beautiful in flower and light and pleasing in foliage, are not so dense in habit as altogether to conceal the texture of the wall veil behind. It is not possible to deal adequately with the beautiful

THE BEAUTIFUL *CEANOTHUS THYRSIFLORUS* VAR. *GRISEUS*.

THE LARGE-LEAVED IVY, *HEDERA COLCHICA*, ON A SHELTER AT GRAVETYE.

A CLOSER VIEW, SHOWING THE BEAUTY OF THE FOLIAGE.

plants in a general article such as this. The Editor hopes, however, to include an article on this family in an early issue. It should be pointed out that it is by no means easy to train *Wistarias* without the use of straining wires, as the natural habit of the plant is to twine itself around the stems of other trees.

Clematises are deservedly popular for house walls, though even here a greater variety is available than is commonly employed. *C. montana* and *C. montana grandiflora* are quite commonly met with. Both need careful training and pruning if they are not to get entirely out of hand. Some old wood should be cut to near the base each year if it is desired to furnish with them the base of the wall, otherwise they quickly become leggy. *C. montana rubens* is a delightful flesh pink form equally as vigorous as the two white sorts mentioned, and with handsome purplish young wood and foliage. It is particularly pleasing against a stone wall. There is now a wide selection of large-flowered hybrid forms, but these will be better left for consideration in a separate article.

Many of the most beautiful and most suitable plants for adorning walls are not, strictly speaking, climbers at all, though they may be trained to cover a considerable area of wall surface. Prominent in this class are some of the *Ceanothuses*, such as *C. rigidus*, with small neat dark green evergreen foliage and small but crowded heads of almost indigo blue flowers; *C. thyrsiflorus*, with pale blue flowers, and its variety *griseus* with larger foliage and pale lilac flowers, an excellent sort; *C. dentatus*, bright blue; and *C. Veitchianus*, also bright blue. The nomenclature of these *Ceanothuses* is much confused in nurseries, but, fortunately, if the wrong species be supplied it is unlikely to be otherwise than beautiful. *Ceanothus Gloire de Versailles* is now common in gardens; it does not, in most localities, require the protection of a wall, but the typical *Ceanothus azureus*, though smaller in leaf and flower, is very desirable, less often seen and more tender. It will reach a height of 8 ft. or so against a wall.

Other invaluable non-climbing shrubs for a wall are the *Pyraecanthas*, both the typical *Pyraecantha* (*P. coccinea*), with its orange-fruited variety *Lalandei*, and the very variable *P. Rogersiana*, with varieties bearing fruits of every hue from golden yellow to red. Then there is the delightful Winter Sweet, *Chimonanthus fragrans*, which, on a wall, flowers in the darkest days of winter. Its curious semi-transparent flowers of greenish yellow have small inner purplish petals. There is, however a variety (*luteus*) with the petals all yellow and a form larger in all its parts called *grandiflorus*, which has flowers of brighter colouring but with less of the characteristic and delightful fragrance.

The White Jasmine (*Jasminum officinale*) is a beautiful and fragrant if rather informal-looking climber, admirable for the walls of stabling or outbuildings. It is too well known to need description. The yellow Jasmine (*J. nudiflorum*), with its bright yellow flowers in midwinter is generally admired, its only drawback being the bare stems upon which the flowers are produced. This may, however, be largely overcome by training the plant on a trellis in front of a small-leaved ivy or other close-growing evergreen climber. The beautiful but not very hardy *J. primulinum*, with larger, more substantial flowers is evergreen, and is a valuable shrub for a south-west wall in more sheltered districts.

For a south wall in fairly mild localities there is little more beautiful than *Solanum jasminoides*, which flowers for a long period in summer. Again, there is the Passion Flower, *Pasiflora coerulea*, and its white-flowered variety *Constance Elliott*, which, while not quite hardy in most districts, are admirable near the coast. The Rose family is too big to consider in detail in this short article, but preference should be given to true climbing varieties rather than to ramblers. Such sorts as the two *Banksians* (white and yellow), the *Gloire de Dijon*, *Mme. Berard*, *William Allan Richardson*, *Abster Stella Gray*, *Réve d'Or*, *sinica Anemone*, the climbing forms of *Lady Ashtown*, *Lady Hillingdon*, *Papa Gontier*, *Mrs. W. J. Grant*, *Melanie Souper* and *Paul Lede* are excellent for south or west walls; while *Mme. A. Carrière*, *Grüss an Tepnitz*, *Gloire de Dijon*, *Ard's Rover* and *Climbing Caroline Testout* provide a selection for those with an eastern aspect.

VIOLAS FOR GARDEN DECORATION

AN IMPRESSION OF THE VIOLA TRIALS AT WISLEY.

The following notes on some of the best Violas that have proved good all-round garden varieties should be of exceptional value to those contemplating growing these beautiful flowers.

THE trial of Violas in the gardens of the Royal Horticultural Society, Wisley, Surrey, during the current year, may be regarded as an unqualified success. Violas in the south of England, so far as the writer is able to determine after a long association with these plants, have never been represented in better form and condition. This is all the more remarkable in view of the unsatisfactory condition of many of the small plants sent to the gardens in February and March last by the trade and others.

Readers will remember how burnt up were the plants of most Violas last year owing to the long period of drought throughout the summer months.

Those responsible for the trial are heartily to be congratulated on the very excellent results achieved.

The trial is not so large or so comprehensive as that which was held under the auspices of the Viola Conference Committee in the Royal Botanic Gardens, Regent's Park, London, N.W., during 1896, but it is infinitely better than the last trial of Violas, held in the old Chiswick Gardens, of the Royal Horticultural Society.

In the present instance, quite a large number of the better Violas are represented, but many notable sorts are conspicuous by their absence. It must not be thought, however, that there is anything wanting in this trial: nothing of the sort! It is

a plant for garden embellishment. For this reason it is very necessary to differentiate between the two sections or types.

As I mentioned before, I have never seen the Viola better grown anywhere in the South of England during the thirty-three years I have endeavoured closely to follow the development of this beautiful flower. Certainly, the moist weather of the latter half of June and throughout July provided the plants with just the conditions they revel in, and to this fact, together with the careful preparation of the flowering quarters, may be largely attributed the undoubted success of the trial. When they were visited by the committee appointed to adjudicate upon the trial, the plants were luxuriating. They were flowering in the greatest profusion, and their real value in the garden, consequently, could be seen and appreciated at once.

The moister weather experienced during the period above mentioned, was, no doubt, responsible for the wonderful growth made in a comparatively short season since the plants were put out in their flowering quarters. I believe the plants were put out a foot apart and, in a great many instances, the intervening spaces were filled with free-flowering growths, on the occasion of the writer's visit during the third week of July last. They were then in the pink of condition, spent blossoms and seed pods were not in evidence and the plants were blossoming in the greatest profusion. Readers will, no doubt, be interested to learn the results of the Committee's adjudication of the trial. This result should be of considerable service to those who purpose planting the Viola another season, and who naturally desire to plant only the very best sorts. I therefore purpose to call attention to the more noteworthy sorts.

The plants are arranged in colours together so that in this way comparison can be made between one sort and another, both in regard to habit and the quality or character of the respective flowers.

Of white sorts there is a large number of chaste varieties mostly rayless, although there are a few dainty sorts with neatly pencilled rays. The best white variety to which an award of merit was granted is Swan. This is a free-flowering plant, having almost circular, pure white rayless blossoms with a big orange yellow eye; the habit in this instance is dwarf and compact, and the plant has a good constitution. Three other sorts, named respectively Snow Queen, Purity and Snowflake, are white sorts, so nearly alike that they are bracketed together in regard to the award of merit granted in their favour. They are rayless sorts, very free flowering, but not so dwarf or compact as Swan. A creamy-white rayless variety is Blanche; it is also known as White Empress. In this case the habit is dwarf and compact and rather free flowering. This plant was highly commended. A rayed white sort that was also highly commended is Alexandra. This is a large flower and one of the best of its type. Queen of Whites is a good white-rayed sort, much admired by some growers.

There is quite a plethora of highly attractive and distinctly beautiful yellow sorts. Some of the large flowered kinds are rather coarse in appearance, while others are refined and beautifully finished in character. The huge flowers of Moseley Perfection are in evidence on plants received from several sources. This is one of the varieties useful alike for the garden and for exhibition. The rayless flowers, however, are rather coarse, but are freely produced on long stout stems, on plants possessing a vigorous, if somewhat coarse habit of growth. For bold effects, however, this rich yellow variety in a mass is very striking and notable. It well deserves the award of merit granted in its favour. Another variety that received this award is Margaret Wood. This is a refined circular rayless flower, colour canary yellow with a rich

THE RICH YELLOW VIOLA SIR R. BADEN-POWELL.

during which season the Viola almost invariably makes rapid growth. It was not so dry as it was during the year 1911, when so many growers completely lost their stocks: still, it was very hot and dry for an unduly long period, and caused many stocks to fail and others to become so impoverished as to exhaust their vitality to no small extent. It will, therefore, be easily understood that, until copious rains had fallen, to assist in the rehabilitation of the plants, the growths were not of the character to promise good material for the perpetuation of the different stocks. Consequently, the supply of cuttings was restricted and the cuttings themselves not at all satisfactory. It was, no doubt, largely due to this fact that the small plants sent to the Wisley gardens for trial did not possess the character and stamina that are seen after a more normal season. I believe many of the young plants on reaching the gardens had to be "nursed," so to speak, with considerable care before they could be regarded as being in a fit condition to plant outdoors in the quarters allocated to them.

an excellent representation of the plant, and the varieties included therein comprise plants possessing habits of growth of varying character, and the colour, form and markings of the flowers are pleasingly diversified.

The Society asked for three plants of each sort to be sent. This is rather few: six plants of each variety I think would have been better. This shortcoming is made up in some measure, however, as several growers have sent plants of the same variety, and of the more popular sorts, there are sometimes as many as twelve plants. The newer and less known sorts are often represented by three plants only.

Violas especially suited for garden embellishment largely predominate, and this is very fortunate, as their free-flowering propensity and their generally acknowledged beauty completely eclipse the exhibition Viola. This latter plant evolves unduly large flowers of good form and pleasing colour, but the habit is, in most cases, thoroughly unsatisfactory. In very few instances indeed can the exhibition Viola be regarded as equally useful as

orange eye. The plant is free flowering, but rather less robust than some others. Quite the best of this type, and more refined than the last mentioned is Dorothea, which also received an award of merit. It is a novelty, and one of the best I have seen this season. The colour may be described as rich canary yellow, with a rich orange suffusion running into the eye, and rayless. The flowers are large and circular, and beautifully finished. The plant is a profuse bloomer and the habit excellent. Two rayless sorts that received the recognition of being highly commended are Kingcup and Royal Sovereign, both rich yellow.

Sir Robert Baden-Powell is a useful flower of beautiful finish, of the richest tone of yellow and rayless. It was shown at a recent fortnightly meeting of the Royal Horticultural Society. Pale yellow rayless sorts are well represented by Primrose Dame, which was highly commended. The plant is free flowering and has a good constitution. An award of merit was granted to Lady Knox, a beautiful primrose rayless oval self, largely grown in British gardens.

Mary Burton, as we saw it, is one of the most distinct Violas and the best of its kind. The colour may be described as pale rosy mauve, with very neat veins or pencillings; this plant well deserved the award of merit it received. J. B. Riding is another consistently good sort and was deservedly granted an award of merit; it is one of the finest and most dependable; colour crimson mauve. Another good rosy mauve sort that was highly commended is Bertha, which is very free flowering.

Mauve and mauve blue sorts abound. Maggie Mott is a soft mauve sort probably more largely grown than any other Viola. This variety rightly received an award of merit. It is free flowering, has a good constitution and is most dependable. A similar award was made in favour of W. H.

Woodgate, a pale lavender blue, almost a pale blue Viola, that is valued for its colour more than for any other quality that the plant may possess. An award of merit was also granted to Mrs. Alsop, a bluish mauve sort, very free flowering, possessing a good habit of growth. When in good form, John Quarten, a light mauve self, is a useful plant in the garden. This variety was highly commended. It is a profuse bloomer, although the blooms are rather small; the constitution is excellent. A deep lavender self that was also highly commended is Perdita; it is a useful sort and is free flowering.

Kitty Bell is quite an old sort, but well maintains its position as a dependable sort of lavender colour. It is a profuse flowering plant and possesses a wiry constitution, highly commended. Mauve Queen received a like award. It is a plant with a sturdy habit of growth, of somewhat compact habit, evolves bluish mauve flowers of a quite distinct tone of colour, and comes into flower rather later than most others. Bridal Morn was also highly commended. As a flower, there is not much to commend it, but it is free flowering and the flowers are of a light mauve blue colour, but its habit leaves much to be desired. One of the newer rayless varieties to command attention is Newton Mauve. This is a rich mauve-coloured flower that is evolved quite freely on a tufted habit of growth and one that has been admired all through the season. This variety was highly commended. Especially noteworthy are the flowers of John Forbes, which may be described as violet shading to rich rose, and, at the time of our visit, the plants were flowering quite freely; highly commended. Another of a similar class which received the same recognition is William Daniels; this is a purple violet flower of good form and of splendid substance. Admiral of the Blues is one of the best rayless rich blue selfs, but the habit is not all we would desire.

It is very beautiful, however, and well merited the high commendation it received. Councillor Waters is an old and tried sort, and is described as crimson purple, and as such it is quite distinct. Its habit is good and the plant flowers freely; highly commended. It is years since Admiration was first sent out, but as seen at the trial it is a quite good plant, flowering in profusion, and yielding useful blossoms of a deep purple blue colour; its habit of growth is excellent; highly commended. Peace received a like award. It is a lovely circular flower, rayless, and the colour may be described as creamy white, upper petals tinted heliotrope. Dumbrian, pale mauve, lighter centre, was also highly commended. It is a dainty flower and the plant is a free bloomer. Mrs. Chichester was credited with a similar honour. It is a large flower, colour white, flaked and bordered bluish purple, paling in warm weather. It is a very dependable plant, flowers in the greatest profusion and possesses a most robust constitution. The best of the fancy Violas is undoubtedly Dr. McFarlane, which received an award of merit. It is a most consistent sort and is quite old. The colour may be described as, upper petals, mauve, lower petals, purple—a quite effective plant in the border, and a good constitution. A similar honour was conferred on President, a flower streaked and blotched crimson; quite distinct. A very old variety named Jackanapes was highly commended. It is a highly popular variety, and the colour is brown and yellow. It is one of the freest of the free-flowered sorts, and is, in the opinion of some people, a most effective bedder. Mrs. Marrison, in shades of mahogany and bronze, is also excellent.

D. B. CRANE.

[We are indebted to Mr. William Vandell, Castle Hill Nurseries, Maidenhead, for the flowers from which the accompanying pictures were made.—Ed.]

VIOLA QUEEN OF THE WHITES.

A STUDY IN MAHOGANY AND BRONZE, MRS. MARRISON.

BULB ORDERS.—III

The Ranunculus—Broad-casting to learn its management—Crocuses—Bulbous Irises—A lament over names—Ornithogalum nutans—Betty-go-to-bed-at-noon—Ixiolirions—Last tips.

IN my previous notes I have written about the "big three" of the various families of bulbs which are included in a present-day catalogue. Here, again, in dealing with the smaller fry I am simply going to draw my bow at a venture. First, however, let me ask for information. Who buys all the Ranunculuses? I am going to buy a few this autumn—so many French; so many Turban; so many Persian. In thus stating my intention I have to confess that it is a very decided case of "if at first you don't succeed, try, try again." I have planted them here, I have planted them there; I have dug out a huge hole to the depth of two feet and filled it up with carefully selected and arranged ingredients; I have put them in ordinary good soil at just the prescribed depth; I have watered them and shaded them with unflinching regularity; Eve did not tend her flowers in Paradise with greater diligence and enthusiasm than I displayed in looking after my Ranunculuses; but all to no purpose. The best results were bad bests. How is it in other gardens? When I look back I can only call to mind one in which I have seen them. That was in that "Lancashire Garden" made famous for all time by those delightful essays of its scholarly owner, Henry Bright. I saw it under the ownership of his son. Ranunculuses were still grown and, as a rule, were a success, but when I was there it was one of their bad years. I do not think I have ever seen them elsewhere. Why? Because I feel sure they come under the head of "difficult" plants. Our grandfathers realised this and in the "Florists' and Amateurs' Annual," published by the *Gardeners' Gazette* in 1840, a writer there states that the best methods for growing them have equalled in number the "specifics for the gout and rheumatism or pills to cure the bile, or remedies for cough and asthma, invented by all the quacks of the last century." "Some," says the writer, "were truly monstrous," on a par with "filling the mouth with water and sitting on the fire till it boils, to cure the toothache." It is consoling in a way to know the difficulties of Ranunculus culture are of long standing, but it is not helpful. I would like to have been able to suggest some varieties, but perhaps the recitation of my failures will do instead, on the principle of the longest way round being the shortest way there. They are such bright flowers, I should like to know a real best way from some successful modern Tyso.

After Hyacinths, Tulips and Daffodils, which comes next in importance? Crocuses or bulbous Irises? I am not going to get off my perch on the gate. A modern garden would be no garden unless representatives of both families were planted in it. My love for the great yellow Dutch crocuses is no less than that of Forbes Watson, who saw so much of the hidden beauty of the ordinary everyday flowers of our gardens. Plant in quantity and leave them alone. With their diminution in size there comes a greater intensity of colour—real or possibly only imagined from their closer juxtaposition. If

you do buy any Crocuses don't leave out Dorothea or Dorothy. It is a pale silvery mauve with glorious orange red stigmas. I have found it, after Sieber, about the most satisfactory of Crocuses for growing in pots. A new lot of garden hybrids have recently been raised with, I believe, only species blood in them. The lovely deep primrose "E. A. Bowles" makes me wish I had a self-filling purse that would allow me occasionally to indulge an expensive fancy. As far as my experience goes, it is as well able to take care of itself as the old yellow. Just as Gibson Bowles suggests Parliament so E. A. Bowles, when you are thinking about Irises,

THE CHARMING AND BRILLIANT HYACINTHUS AZUREUS.

suggests Cantab. He raised it. If we describe *reticulata* as Oxford blue in colour, Cantab may be called Cambridge blue—neither description is strictly accurate, but it marks their difference and gives a rough idea of their colour. Would that *reticulata* were less expensive so that it might be grown *ad lib.* in pots. It would be so useful to have a dozen low pots or small pans of it in early January. With me this treatment almost invariably means death to the bulbs. My soil does not really suit either Spanish or Dutch Irises.

Spanish sorts which I suggest are Prince Henry (bronze), Souvenir (pale silvery mauve), Flora (white and mauve), Royal Blue (deep rich blue), Sweetheart (primrose) and Cajanus (rich yellow). The Dutch Irises are a useful race, flowering from ten days to a fortnight before the Spanish and being more amenable to the conditions of life in pots. I cannot help an aside here. It is to shed a tear over the degeneracy of their names. A superb race of garden flowers, raised by a Dutchman, matured and grown on Dutch land, and then named with righteous pride after the master-painter-geniuses of the Dutch race, are no longer Hals, Rembrandt, Van der Helst, Potter and Sandredam, but have such colourless names as Golden Glory, White Excelsior and True Blue. It is a poor exchange to be told a certain flower of a certain race is blue or yellow or white from the fuller meaning that is attached to the painter

name. They are by no means exhausted. There are still Adriaan van Ostade and Jan van Huysum to be used; and when all are exhausted it will be high time to think if the making of these flowers without end has not gone far enough. Try, if only to remind yourself of the great painters of Holland—Rembrandt, Frans Hals, van Evedingen, Voerman (the magnificent white) and Van der Helst, which after two years' experience I single out as about the best when beauty and constitution are taken into account.

When a plant is championed by Sir Herbert Maxwell it is certainly one to be reckoned with. I can recall no flower with such a real silvery look as *Ornithogalum nutans*. It is very hardy, not in the least particular about soil, and very uncommon-looking. It is useful and uncommon-looking in vases either alone or in combination with other flowers, especially those of a pink shade. The casual person might easily imagine that if he heard these

two nicknames, "Go-to-bed-at-noon" and "Betty-go-to-bed-at-noon," that they stood for the same plant. It is not so, by any means. "Go-to-bed-at-noon" is *Tragopogon pratensis*, which, since the war, has suddenly appeared as a weed in my garden and is none other than the widely known Goat's Beard. "Betty-go-to-bed-at-noon" is our very local name for *Ornithogalum umbellatum* (see "English Plant Names," by Britten and Holland, page 40, where Ellesmere (Salop) is given as the locality for its usage—we are nine miles from Ellesmere—old folk still speak of it under this name), which also is in the Rectory garden where it has seeded itself "all over the shop" and is generally known as Star of Bethlehem, as it has been from Tusser's day onwards. The nomenclature of plants is often most confusing; in fact, it is frequently on a par with "the Rule of Three" of the nursery

rhyme. I want to sing the praises of an infrequently-met-with bulb, but for the life of me I do not know what I ought to call it. If the "Kew Hand List" is the final court of appeal, I must write it down as *Ixiolirion montanum* var. *tartaricum*; but if I wanted to buy a few bulbs from van Tubergen of Haarlem I would have to write for "Pallasii (*tartaricum*)" and then to find out something about it from Nicholson's Dictionary I would find "*tartaricum* syn. *montanum*." Beware, then, in buying. Say you want the rich deep purple-blue, which is a good doer. I do not know how it came about that the genus was called *Ixia* Lily (*Ixiolirion*). The general effect in gardens and vases reminds me much more of a *Brodiaea*, especially *B. Purdyi*. Its inflorescence is neither a simple spike nor an umbel, but something between the two. The purple-blue colour of the flowers is much more like a *Brodiaea*. I have had fine pots of it in a cold frame from which frost has been excluded. I have had just once a couple of stray plants turn up in a border outside, but it is only in the warmest and most favoured parts of Britain that open-air culture should be attempted. I must pay the penalty for this digression. My final tips must be but bare names—*Brodiaea ixionides splendens*, *B. Bridgesii*, *Hyacinthus azureus*, *Ixia* (var. *Englishtom*), *Erythronium Hartwegii*, *E. grandiflorum*, *E. revolutum*, White Beauty and E. Johnsoni and the pure white *Milla* (*Triteleia*) *uniflora*. JOSEPH JACOB.

COLOUR EFFECTS IN THE LATE SUMMER BORDER

BY GERTRUDE JEKYLL, V.M.H.

It is to be regretted that so many people make it a rule to be away from home in August, for that month is just the time when a well arranged flower border is likely to be at its best. It is necessarily so because the plants that are of the noblest aspect, of the greatest stature and of the most gorgeous colouring, such as Hollyhocks, Dahlias, Cannas and Pentstemons, are then in bloom. However, August has July

on one side and September on the other, and, as the season of the main flower border extends over these three months, it is only the middle portion that is lost by those who are away.

Taking the main features of an existing border that faces nearly south, the western end has flowers of blue, with tender coloured accompaniment of white and pale yellow. The Delphiniums of July have had their tall seed pods cut, leaving the stems

about 5ft. high. Clematis Flammula, planted behind, is coming over and resting in these cut stems and will be a sheet of bloom in September. A bush of Ceanothus Gloire de Versailles still shows a misty cloud of its grey-blue bloom. Further forward in the border are tall white Snapdragons and a drift of the charming dwarf Agapanthus Mooreanus, and then the stronger blue of a carefully kept strain of Delphinium consolida. Next at the back, is the good old Dahlia Mrs. Hawkins, pale yellow with a warmer shade towards the outside of the petals, and then a pleasant mixture of primrose Sunflowers peeping through and showing above a mass of the creamy plumes of Artemisia lactiflora. This is backed by a goodly bush of Gold Privet, whose yellow is actually brighter than that of the Sunflowers.

Now comes a yard or two without much positive colour except for some short yellow Snapdragons in the front with the rich deep green of Crested Tansy, and a good show of bloom of Buddleia Veitchiana on the wall at the back. A large group of Chrysanthemum maximum is here out of bloom; behind it is the tall Helianthus orgyalis, the greater part of it trained down over the Chrysanthemum and a patch of Eryngium of earlier bloom. This pulling down makes it throw out flowering shoots at every axil, and in September it will be a spreading sheet of bright yellow. Now comes a gold Elder at the back, cut back every year so that it makes a good head of its yellow green leaves. Rudbeckia Golden Glow, of lanky growth, is partly trained into the Elder and partly pulled down. Again there comes a patch of pale Sunflower in a setting of Artemisia lactiflora, and in front a yard or two of Helium pumilum giving several weeks' display of its splendid yellow.

From here onward the colouring becomes warmer, with a group of the low-toned copper-red Dahlia Oban accompanied by the reddish leaved Atriplex hortensis, a plant that shows redder as the season advances and the bloom turns to a mass of flattish seed pods. The colour strengthens through Tritomas tall and dwarf, and orange African Marigold, both as yet only beginning to show colour, but full of promise for September. Helium striatum is behind the Tritomas, and in front is a gorgeous mass of Helium cupreum, orange Pot Marigold and a double orange dwarf Tropaeolum. Now is coming the most sumptuous mass of the border's colouring. At the back is a mixture of darkest claret with deep blood-red Hollyhocks, intergrouped with bushes of Prunus pissardi and with a tall dark claret Dahlia. Shorter Dahlias of strongest red come next to these, and nearer still a brilliant pot-pourri of scarlet Pentstemon, Scarlet Phlox and Monarda, leading to orange red Snapdragon and orange Gazania next the path. A deep red drift also streams away from the rich warm colouring of the back; it is of dark velvety Snapdragons, with a good French variety of Amaranthus and Iresine coming forward and mingling with Geranium Paul Crampel.

The colour now passes again through orange to yellow with Rudbeckia speciosa in the front, leading to the pale primrose-coloured African Marigold and the good striped grass Glyceria aquatica, with the clear pale yellow of Calceolaria amplexicaulis and the yellow, white-splashed, Mentha rotundifolia. Striped Maize is at the back. A patch of Eryngium that was in flower in July has been shrouded by a white Everlasting Pea, and as this goes over it is again covered with a late blooming hybrid Clematis. This is followed by a cloudy mass of the greyish blue purple of Campanula lactiflora, and then comes a bold group of Yuccas.

The length of the border so far is 130ft., but now a path cuts across, leading to an arched doorway in the stone wall. The arch is now obscured

THE EASTERN END OF THE FLOWER BORDER AT MUNSTEAD WOOD.

THE CROSS PATH.

by the growth of *Choisya* on each side; through the open door one sees a more distant arch of Yew that leads out of a part of the garden that is beyond the wall. The tall tree-like growth to the left of the opening is *Magnolia conspicua*, loaded with bloom at the end of March. Beyond the cross path there is a shorter length of border, about 50ft., also beginning with *Yuccas*. It has flowers of light colouring, answering, with quite different treatment, to the blue and white of the western end. Here the flowers are purple, pink and white; pink and white *Hollyhocks* at the back and white *Dahlias*, with one or two of the earlier *Asters* of which the beautiful *A. acris* is one; *Salvia virgata* for July and the showy mauve bracted *Clary*. The

Clary is cleared away when the bloom is over, as it is a biennial, and its place is taken by some pots of *Hydrangeas* plunged here and also in suitable places elsewhere. There are *Snapdragons* white and pink and *Campanula lactiflora* and a general front planting of grey and glaucous-leaved plants — *Seakale* and *Funkia Sieboldi*, *Cineraria maritima*, *Santolina* and *Stachys*, with *Ageratum* both tall and dwarf filling any vacancies.

A BEAUTIFUL WHITE ESCALLONIA, *E. MONTEVIDENSIS*.

HARDY ESCALLONIAS FOR PRESENT PLANTING

MOST of them being evergreens, the *Escallonias* should be planted in early autumn or, failing that, the later spring. As to the hardness of this beautiful race of South American shrubs, I can only say that most of those mentioned here have come through some severe trials (15° to 20° of frost) with little more injury than shrivelled foliage. Even when the ends of the branches have been killed by frost the bushes have come away in spring with the vigour of a Scotch *Fuchsia*. In all cases they are growing in well drained, light loam (rather stony, which they seem to like) and quite in the open. Doubtless, *Escallonias* are seen to greatest perfection in seaside gardens, and in those of our milder counties; but that many of them, including some of the best, will succeed in less genial climates there is sufficient proof. In very bleak districts these shrubs may be used on walls with admirable effect.

The old *E. macrantha*, with its large, glossy leaves which, when young, emit a delightfully aromatic perfume, is still one of the handsomest and best of its race. It will make a fine specimen shrub growing up to 8ft. or 10ft. high, with an even greater diameter, and is not less pleasing as an ornamental hedge. There are several forms of this species, varying considerably in the colour and size of their flowers and foliage. In a good form the

waxen, tubular blossoms borne in bold clusters should be about an inch long, nearly half as wide and of a deep crimson. *E. Ingrami* is apparently a form of *macrantha*, and *rubra* also comes close to the latter in form and habit. But whilst both are inferior in flower and leaf, *Ingrami* appears to enjoy the merit of superior hardiness. One of the best varieties of *E. macrantha* is one I have seen sent out under the name of *sanguinea* (*punctata*), which excels in the brilliant colouring of its flowers.

Whilst the above are not usually in full bloom until the later summer, the splendid hybrid, *E. langleyensis* (*macrantha* x *Philippiana*), will often commence in June and continue to flower until well into autumn. This is a very vigorous and in every way an admirable shrub, hardier than many others, and a rapid grower which throws out its gracefully arched wands to several feet in length in a season. The foliage is rather more sparse than in the above-mentioned, and the smaller leaves are a yellowish green. The bright, blood-red flower clusters are longer and more prominent than is usual in others of this genus, and when the arching branches are

wreathed with these in the generous manner peculiar to this hybrid, the effect is most beautiful. The individual flowers are about ½ in. in diameter, and a well grown shrub will attain to 10ft. in height and as much in width. Save when one is obliged, on account of climate, to grow *E. langleyensis* on a wall, it should always be given tree space to make a large natural mound, for in no other way is it seen to full advantage.

E. Philippiana, despite the fact that it is said to be "evergreen" in not a few books and catalogues, is here thoroughly deciduous and quite one of the hardiest of all. It makes a good-sized bush, consisting of dense growths of fine interlacing branches which, about midsummer, bear myriads of little white flowers, sweetly scented. The leaves being very small, a well flowered specimen of *E. Philippiana* will look as white as the Blackthorn in March.

Perhaps the finest white is *E. floribunda** (*montevidensis*), which is rather more tender than any of the foregoing, though it has never had more than its tender tips injured with us. *E. floribunda* attains a height of 6ft. to 8ft., the oar-shaped, apple-green leaves being glossy and inclined to be red in the midrib when young. The flowers are produced at the ends of the new shoots in August or later, in large, loose clusters of pure white blooms, very conspicuous and fragrant.

E. "Donard Seedling" is a tree-growing, vigorous variety in a pale blush, hardly producing so fine a show as "Edinburgh," said to be a hybrid between *Philippiana* and *sanguinea*. This is a first-rate *Escallonia* much after the style of *langleyensis*, very hardy and an abundant producer of vivid pink flowers. Another exceptionally striking hybrid is *E. exoniensis*, which goes up to 12ft. or more, bearing creamy-white waxen flowers; and *organensis*, with coral-red blossoms and a reddish tinted foliage, is a good species. A. T. J. N. Wales.

*According to Bean's "Trees and Shrubs" *E. montevidensis* is distinct from *E. floribunda*, and has larger flowers.—[E.]

HARDEST OF ESCALLONIAS—*E. PHILIPPIANA*.

ALPINES UNDER GLASS

THOUGH, in some quarters, a prejudice still exists against growing alpines in any other way than in the open air on the rock garden, there cannot be any doubt that Alpine house culture for these beautiful plants is gaining fresh adherents every year. Artificial? Yes. But so is the rock garden, when compared with the free open mountain and pasture land, and a system of culture which provides such a charming effect during February, March and

April as the alpine house affords does not merit much criticism. True, that everything is confined in a pot or pan and set out in rows confined within four walls; but when so displayed the plants become individuals and less one of a crowd, so that their exquisite beauty and charm appeal with far greater force and are much more highly appreciated.

Though I have singled out February, March and April for special mention, do not let us overlook the fact that this is the flower time, and that by

judiciously selecting the plants that are to be grown, the house may be crammed with interest, even as early as December, when, as a rule, the average garden has but little of interest to show. One is called upon to stoke no fire, so that cost is reduced to a minimum; one has no worry as to whether Jack Frost has nipped in and ruined the labour of months; while the house is left vacant just at the right time to fill up with tomatoes or summer flowers, as the owner's fancy may dictate.

The questions arise: "What kind of house is the best for growing these miniature gems?" "What are the other necessary accessories?" and "When is the best time to start?"

THE HOUSE.

The first essential is that it should be a span roof building (preferably running north and south), not too lofty and right out in the open, so that it will not be shaded either by trees or buildings. It must be unheated. Let there be no doubt on that point: heat, even the gentlest warmth, is not only unnecessary, but positively harmful. Many and many a house that has been used as a greenhouse and that is fitted with hot water heating can be adapted by the simple expedient of not using the fire; but no heat must be used—that is final.

The sole object of an alpine house is to afford protection against rain, snow and wind, so that the longest possible period of flower perfection can be enjoyed, so that free and abundant ventilation is of the utmost importance. Too much emphasis cannot be laid upon this; a damp, clammy atmosphere being, with artificial heat, one of the two things which the plants will not tolerate. Bottom, side and top ventilators should be provided upon the most generous lines, so that night and day, unless under most exceptional circumstances, a current of air will be passing through the house, carrying away all superfluous moisture with it. The roof ventilators ought not to be quite closed at any time, those below the stage and at the side being used according to the state of the weather. A closed staging is best, consisting of a layer of slate upon which a couple of inches of coke breeze have been spread, though proper facilities must be provided for draining this or it will produce damp.

So much for the house and its fitment, but—in addition to this—provision must be made for the happiness of the plants at other seasons of the year, while they are not occupying the house. The most satisfactory, from the cultural point of view as well as saving labour, is an ash bed in the open ground where the pans can be sunk to the rim and so kept cool and moist.

THE PLANTS TO GROW.

This leads us, naturally, to the best period at which to make a beginning, the material to use, and general cultural management. Personally, I think there is no better period than autumn, for so many plants can then be potted on, so many seedlings have made good progress and so many bulbs can be procured from the dealers, that one is sure of a very good display the first spring. Apart from the consideration of bulbs and seedlings, however, there is no season except the middle of the summer, during which a good beginning cannot be made.

Of bulbs and tubers which can be planted during the next few weeks a special note should be made of the following: Anemone blanda, with its splendid starry blue flowers; Anemone nemorosa Robinsoniana, the most and choicest variety of our Wood Anemone; Crocus species; Dog's Tooth Violets; Fritillaria aurea, and F.F. citrina, Meleagris, persica, pulchra, and recurva; Irises in a large range of species, such as alata (which flowers before Christmas) Bakeriana, orchoides and reticulata; and Muscaris in both white and blue. Among the most charming plants of all are the

A CHARMING BELL-FLOWER, *CAMPANULA TYMONSII*.

SILVER AND BLUE, *ERYNGIUM PROSTRATUM*.

This recently received an Award of Merit from the Royal Horticultural Society.

CORRESPONDENCE

A LATE-FLOWERING RHODODENDRON SPECIES.

miniature Narcissi—cyclamineus, Bulbocodium, minus and triandrus; while, as brilliant companions, the little known but interesting dwarf Tulip species provide us with a host of pans for successional purposes. Everything in the way of dwarf bulbous rooted plants is very attractive and the flowers open in spotless purity under the glass protection.

Of other plants it would scarcely be possible to write exhaustively within the limits of an article, but Primulas and Saxifrages alone (to mention but two genera) would be sufficient to furnish a large house for many weeks with such a display of lovely blossom as few who have not experimented with indoor alpiners would be disposed to credit. Just think for a moment of the various beautiful flowering "Saxies": the red "mossies," delicious alike in bud and blossom; the earliest tufted gems, such as *Bursleriana Gloria*; the *Megasea* section; and then the gracious encrusted forms. One can scarcely imagine a more dignified picture among all the wealth of the tropics than a fine example of *Saxifraga longifolia* in full flower. The great arching stem, rising 1½ ft. to 2 ft. high, smothered with myriads of its white flowers, springing from a huge rosette of silvery foliage, forms a glorious picture indeed.

With Primulas, too, the story is the same, save that here is an even greater diversity of form, colour and perfume. It is one of my dreams to possess a small house, filled entirely with hardy Primulas, in some future April and May that is to be and, when I do, I know that the result will prove that this is not the madness of an enthusiast, but that a real garden picture will result, a picture crowded with varying form, aglow with vivid colour and crammed with interest to garden lover, flower lover and botanist alike.

But even yet we have not exhausted possibilities. There is still a mighty host of Achilleas, Adonises, Campanulas, Daphnes, Ranondias, Haberleas, Scillas, Sempervivums, Statice, Trilliums, Violas, etc., that are no less interesting or beautiful. From the end of May onwards, all the plants should be taken into the open again and plunged to the rim in the ash-bed where a couple of good waterings a week will be all the care that they need. Two of these ash-beds are better than one, although both must be in an open position and not overhung by trees. One must be in shade and another in full sun so that all classes of plants can be suitably accommodated, Primulas, Cyclamens, Trilliums, etc., going into the shaded bed; sun-lovers such as the Saxifrages, Sempervivums, Irises, etc., enjoying the one in full sunshine.

The alpine house certainly provides us with one of the cheapest, most interesting spring features in the garden, and one can but hope to see an even larger extension of such a beautiful feature in the near future.

H. W. CANNING-WRIGHT.

[Mr Canning-Wright echoes the general experience in advocating a low house for Alpines. Some of the best Alpines ever grown under glass, however (and the least drawn) have been grown in tall (Palm) houses (quite drip-proof) where there is sufficient atmosphere to produce a little condensation on the foliage at night.—ED.]

satisfactory, and shall probably be faithful to in the future, are, Lady Grisell Hamilton, lavender; Mrs. Hardeastle Sykes, pink; and Nora Unwin, white.—G. J.

"SOMERS" SHIRLEY POPPIES.

IN early spring I wrote about "Annual Flowers for Old Folks," and proceeded to carry my preaching into practice, but "it is always the unforeseen that occurs," and the loveliest of all my annuals this year have been "Somers'" Shirley Poppies. He very kindly sent me some

A FINE PLANT OF THE LATE-FLOWERING RHODODENDRON AURICULATUM.

crosses, we may have a July-flowering section of good hybrid Rhododendrons, which should prove a great addition to that wonderful family.—F. GOMER WATERLER, *Bagshot*.

SWEET PEAS.

WISDOM comes by experience in gardening as in all else, though human frailty is always apt to be beguiled by enticing words. For some years I have been tempted by the descriptions of Sweet Peas in the many seed lists that come to hand, and have often been captured by the alluring qualities ascribed to the numerous novelties that are brought forward from year to year. But thinking over some older kinds, and remembering which of these have given me the most genuine pleasure, I have reduced to three the kinds that are to me the most desirable. They are beautiful, fairly sweet scented, and the colours of the three in a mixed bunch are an unending delight. All further trouble or uncertainty as to what kinds of Sweet Peas to provide is at an end, for when complete contentment is achieved there is no need to look for further perplexity, or for further experimental excursions into the unknown. My own choice excludes the colours approaching salmon, scarlet and purple, finding greater delight in some of the tenderer shades. Those I have found so

seed last year which I sowed, but only a few plants came up and soon disappeared in the drought, to my deep disappointment. But after sulking for a whole twelve months, behold! this season they came up freely and were a daily delight for about two months. Never! never! have I seen anything to equal them. Well may "Somers" dilate on them! They truly surpass any Shirley Poppies I have ever seen. Neither description nor photograph can convey their beauty. The Rev. Wilks himself would turn green with envy. Of course, I am saving seed in the hope of perpetuating them and doling out little dollops of the same to a favoured few of my chief garden chums.—ANNIE AMATEUR.

SWEET PEA ROYAL SCOT.

ON page 424 of your issue dated August 20th your correspondent "H. L." presents his experiences with several popular Sweet Peas. The article is very interesting but in its final stage-reference is made to the variety Royal Scot as requiring shading from the hot sunshine. It is quite obvious that the very rich colour of this variety suggests that some shading is necessary, but my experience is that it is not required; in fact, it seems to revel in the sunshine. In the most sunny portion of my gardens I have too plants of

Royal Scot trained on the outer side of bamboos, where they get the benefit of sunshine practically all day long, and no burning of the bloom has been noticed.

Royal Scot is such an excellent grower—nearly all four flowered spikes—that I confidently suggest to "H. L." that he give it another trial; in fact, its delightful perfume should appeal to an enthusiast like "H. L."—HARRY SCHOLFIELD, *Heysham*.

A BEAUTIFUL SALVIA.

IN *Salvia dichroa* we have one of the most beautiful representatives of the Sage family but in this part of the country it is not quite hardy and must be grown in a sheltered position, although in more favoured districts it could undoubtedly be grown in the open. The species is not common in gardens, although it is by no means new, as it was introduced in 1871 by Mr. G. Maw, of Crocus fame, who collected it at the base of the Greater Atlas, south of the City of Morocco, at about 2,000ft. below Tasmeroot. Mr. Maw flowered it in August of the following year in his garden at Brosley in Shropshire. In Nicholson's Dictionary the height is given as 2 to 3ft., but this is misleading, as it grows 6 to 8ft. high, and a good specimen, bearing its fine spikes 3ft. long, is a beautiful sight. It has quite 12ms. out at once. The corolla is 1½ms. long, the upper lip being bright blue in colour, arcuate, pubescent, the lower lip of the same length as the upper and three lobed, the lateral lobes being pale blue, oblong in shape, and recurved, the central white lobe being concave, orbicular, and pendulous. The leaves, which are from 5 to 10ms. long, are roughly corrugated on the upper surface, with hairs on the reverse. It is closely allied to *Salvia bicolor*, and in the Index Kewensis, *Salvia dichroa* is referred to as *S. bicolor*, but there are considerable points of difference. The flowers of *S. bicolor* are bright blue with yellow dots on the upper lip, and although the flowers of *S. dichroa* are chiefly blue, the centre lobe of the lower lip is white, as already stated. The leaves of *S. dichroa* at the base are oblong, acute, irregularly cut into large obtuse lobules that point to the apex, while the radical leaves of *S. bicolor* are deeply cordate, sinuate and toothed, much cut with spreading teeth and lobes, and while the hairs on the stem of *S. bicolor* are spreading, those of *S. dichroa* are reverted. The plant is not difficult to cultivate and can be

easily propagated by division, root cuttings, or from seed.

The illustration is of a plant that has grown outside at Cambridge for a number of years against an east wall of one of the cool houses, where it gives an attractive display every year, making it quite evident that it deserves to be better known than it is at present. Its free flowering and stately habit makes it a plant worthy of a place in all gardens where it can have that slight amount of protection which it requires.—F. G. PRESTON (*Bot. Garden, Cambridge*).

A FIELD OF YELLOW VERBASCUM LYCHNITIS.

IN the *Botanical Gazette*, 1850, page 251, the late Professor C. C. Babington recorded this plant "On the slope of the hill above Bossington, near Porlock . . . far above cultivation; and on the common near the mouth of the brook below that village, June, 1850."

Not only does this rare Mullein still grow in the vicinity, but a small enclosure on the steep hillside above Bossington was so yellow with it in July, 1922, that it formed a yellowish patch visible from the hills several miles away. Normally white or cream coloured, the Bossington plants are all a clear lemon yellow, with a small purple blotch at the base of each petal; and the stamens are orange. The flowers are also smaller than in the type. This is the variety *micranthum* of

THE STATELY SALVIA DICHROA.

Moretti, very rare in this country, as pointed out by Mr. S. T. Dunn in the *Journal of Botany*, 1894, page 23.

The small field above Bossington is of very stony ground and was at some recent time planted with Potatoes, for numerous Potato plants appear this year—also a considerable number of Thistles. On July 16, when I photographed the scene, I counted about 125 plants of the Mullein averaging 4ft. to 5ft. high. Many are branched to the ground, and one of the largest had about seventy branches over 6ins. long and numerous shorter branches on the top 18ins. of spike. Some of the leaves lie flat on the ground, the largest being a foot long.—H. S. THOMPSON

HOW TO TRAP MOLES.

IN your issue of August 19th is an interesting letter on the above-named subject by A. C. C., in which he says "you may tread heavily close to the spot where he is heaving up a molehill (provided you do not tread on his tunnel), without causing him to stop work." Now, I find that the best way of exterminating moles is to shoot them when they can be seen moving the earth, but the chief difficulty is in approaching softly enough for the mole not to hear or feel one's approach. If they do, they at once stop and stop for good. I see in Wood's "Natural History" that he agrees with this, and I cannot understand how A. C. C. comes to make his statement. I have cleared a whole field of moles in a few days by going out at 11 o'clock (or 12 o'clock summer time), which is the hour they will be found working. My gardener also shoots them and says the chief difficulty is to get near without their knowing.—THACKERAY TURNER.

WHERE VERBASCUM LYCHNITIS GROWS WILD.

GARDENING OF THE WEEK

FOR SOUTHERN GARDENS.

The Kitchen Garden.

Herbs.—Take the opportunity afforded by a fine day to cut those herbs required for use in a dried state during the winter. Previous to tying them into bunches for suspension in a dry, cool shed spread them out thinly for a few days to complete drying. Should Sweet Basil be required, sow some seed in a moderate temperature, and when the seedlings are strong enough prick five to seven out into 5in. or 6in. pots and keep them growing in the same heat until good bushes are secured, when they may be transferred to cooler quarters.

Spring-Sown Onions are, owing to the cold, wet July and early August showers, very slow in ripening off. Directly growth is complete pull the bulbs up and lay them on trellis to finish drying and ripening. Failing suitable conditions for them to be finished properly outside, an open airy shed or some dry cold frames must be utilised; for a thorough ripening is of great help in keeping the bulbs through the winter and early spring months. Onions having a thick neck are generally bad keepers, so should be drawn upon first for kitchen supplies.

The Flower Garden.

Lavender.—Whether the flowers have been cut and dried for indoor use or not, the plants in most instances will now be quite over and the majority of established hedges will be all the better for a good trimming back with a pair of shears. Should the plants have become large and unshapely, and perchance overgrown too, no fear whatever need be felt in cutting well into the old wood, as they generally quickly respond with an abundance of new growths. Cuttings inserted now in a cold frame in sandy soil will root readily and be available for autumn or spring planting as required.

Nepeta Mussini.—This extremely useful old garden favourite may be used in many ways with most pleasing results, and it is always advisable to have a good stock on hand. Plenty of cuttings are now available, and will root readily in light soil in a close cold frame. The old plants, too, if necessary, may be split up now into small pieces and replanted. Planted in front of a tall-growing Lavender, and linking up bold beds of the annual Delphinium in two shades of blue, it gave a most pleasing picture here this summer.

Penistemons.—Where old plants can remain and the soil and district are favourable for a fairly safe wintering the results amply repay the second season. Southgate and Newberry Gem seem particularly free the second season. It is, however, advisable to always have young stock coming along, and the present time is suitable to see to this by inserting cuttings in a cold frame about 3ins. apart. Keep close until rooted and afterwards always give plenty of air except during severe weather.

Rose Cuttings.—Quite good results are obtainable from cuttings of some of both sections, dwarf and climber. To attempt to increase all varieties of the former will probably be to court failure, and the Teas had better be omitted. Ramblers generally are easy to root so long as good firm wood is used after the tree has flowered. It is important to use a firm sandy compost and see that at least half the length of the cutting is in the ground. It is, certainly, not necessary for cuttings of the climbing section; but, if preferred, cuttings of the dwarfs may be placed in pots under a bell glass. The present is a suitable time for inserting the cuttings.

The Hardy Fruit Garden.

Apples and Pears.—Ripe and ripening fruits of the early Apples and Pears require watching carefully now, and the latter should be gathered a few days previous to becoming quite ripe. Pears, and more particularly the early ones, are most easily damaged, so should be carefully handled, and when gathered placed in a cool, airy room. Some of the very early Apples are not worth much labour and expense as regards storage, but are better to be used up as far as it is possible to do so direct from the trees, keeping storage quarters available for more profitable later varieties.

Peaches must not be allowed to get too far advanced before gathering them or they will probably prove quite second-rate in flavour. Rather gather them when it requires a decided pull to remove them, and give them a few days in the even temperature of a store room.

Fruit Under Glass.

Strawberries in Pots.—The first batch that was potted should now be well supplied with roots; and to enable the plants to build up plump, strong crowns which will respond to early forcing it will be best to feed them with diluted farmyard manure water. About once a week will be enough the first three weeks, but afterwards it may be used for every second watering. Keep all weeds and runners removed.

H. TURNER.

(Gardener to the Duke of Northumberland.)
Abury Park Gardens, Guildford.

FOR NORTHERN GARDENS.

The Kitchen Garden.

Seakale.—Give the plants every assistance so that fine strong crowns may be had for forcing purposes. An application of guano, followed with a light sprinkling of sulphate of ammonia at a later date, should be given, hoeing the dressing lightly in between the rows. Old established plantations may also be considerably strengthened at this time by copious supplies of liquid manure.

Mushrooms.—Where material has been gathered and got into the right condition for making up the beds, no further time should be lost in having the beds prepared. Spread the manure evenly and have the bed thoroughly consolidated by treading and beating firmly. The depth of the bed made upon the flat need not be so deep as will be required at a later date when the weather becomes colder, 18ins. being deep enough for present purposes. When finished, a bottom-heat thermometer will indicate when the heat of the bed has declined sufficiently to allow for spawning being done. This should take place when the mercury falls to 80°. Use fresh spawn and break into small pieces about 2ins. square. Insert them just under the surface of the bed, about 5ins. apart each way. Make the surface quite firm again, covering over with finely sifted loam. This should be moist enough to allow for beating down and leaving perfectly smooth with the back of a spade. Cover over with a light dressing of hay or short litter. If the bed retains its heat and the temperature remains steady, Mushrooms should appear in about five or six weeks' time. When the mycelium begins to run freely remove the covering.

Early Sown Carrots should now be lifted and stored in a cool dry shed, placing sufficient sand among them to keep the roots moist. If left too long in the ground the roots split readily. More especially does this happen on heavy ground.

Cucumbers.—Fire heat will now be necessary in late planted pits if a profitable crop is to be produced. Less moisture will now be required owing to the shortening days and want of sunshine. Give a surface dressing of a quick acting fertiliser to plants in bearing and thin out all unnecessary growth.

Fruits Under Glass.

Melons.—Where crops are ripening care should be taken that the fruits are not allowed to hang too long before being cut. Directly the crack round the insertion of the stalk appears the fruit may be cut. Store the fruit in a cool room for some time. Keep the house dry, but allow free ventilation during suitable weather.

Replanting Peach Trees.—If for any cause the renovation of the border has been decided upon in the early Peach house, the work may be undertaken whenever the leaves show signs of maturity, with every prospect of the work turning out successfully, as owing to the trees still carrying their foliage new roots will at once be emitted and the trees will as a result recover more quickly than if left till the foliage has fallen. Provided the required quantity of compost has been prepared, the actual lifting and remaking of the border, wholly or partly, can be quickly effected. See that the ends of all broken roots are pared smooth with a sharp knife before replanting. The new compost should be settled about the roots by giving copious waterings, and this is best done before the final or topmost layer is spread and levelled down. Care should be taken to see that the roots are kept in a moist condition during the interval elapsing between their removal from the old soil and their being spread out aresh in the new compost. Mats soaked in water and rolled round the roots will serve the purpose.

Early Vines.—The laterals of early forced vines will now be sufficiently ripened to allow of

their being shortened. Remove about one third of each shoot at the same time removing all sub-laterals from the remaining parts. This pruning proves of considerable benefit in enabling an increased amount of light to ripen the wood, and by concentrating the sap will assist the buds that are to produce fruit next season. The border should still be kept reasonably moist.

JAMES McGRAN.

(Gardener to Sir Henry H. Houldsworth, Bart.)
Coodham, Kilmarnock.

GREENHOUSE AND CONSERVATORY.

Annuals for Pots may be sown from now until the end of the month. There is quite a number of hardy annuals that are general favourites for this purpose. Mignonette should, of course, always be included. Other plants specially suited for this purpose are Godetias and Clarkias. In dealing with the former Godetia Lavender should not be overlooked, as it makes a fine plant and is distinct in colour from any of the others. Schizanthus are very popular, and there are quite a number of good strains. The following are also exceedingly useful: Larkspurs in variety, Scabions, Chrysanthemum segetum varieties Evening and Morning Star, Chrysanthemum carinatum and varieties, C. inodorum Bridal Robe, Collinsia bicolor and its variety candidissima, Viscarias, Antirrhinums (although not strictly annuals, are generally treated as such), Trachymene carulea and Gilia capitata. This by no means exhausts the lists, but it will show what a variety one can choose from. The essential points to bear in mind are thin sowing in the first instance, pricking the resultant seedlings off before they become crowded, cool treatment, with full exposure to light and air at all stages of their cultivation, ample ventilation without draughts whenever the weather conditions are suitable, prompt attention as regards staking to those plants that require it and, of course, careful watering at all times. If these annuals receive a check, it is hardly ever possible to pull them round, as they have little power of recovery compared with plants of a perennial character. Seed should be sown in pots or boxes of light rich soil. Plants like Larkspurs and Mignonette that transplant badly should be sown directly into their flowering pots, 48-sized pots being best for this purpose. After sowing stand the pots or boxes in a cold frame or cool house, and shade them with sheets of paper until such time as they germinate. As already stated, these plants require a light, rich compost, which should be made fairly firm, as this tends to produce sturdier growth. Some old mushroom-bed manure is excellent to add to the potting compost.

Violets.—To attain the best results with these plants they must be well established before winter, thus there should be no delay in lifting them and transferring them to frames. Any frames that have been used for growing vegetables are excellent for this purpose. If such are not available, the frame may be partly filled with leaves, finishing off with at least a foot of good rich compost. The compost in the frame should be allowed to settle down for at least a week before the plants are placed therein. If the weather be at all dry, the plants should be given a thorough soaking at the root the day before it is proposed to lift them. When planting they should be kept close up to the glass and well watered in and kept close for a few days, shading them for a few hours each day in bright weather. In a few days the frame-lights may be removed altogether until such time as inclement weather sets in. If it is desired to grow any in pots, they should be lifted with a good ball of soil attached and carefully potted up in 6in. or 7in. pots, standing them in cold frames and keeping them close for a few days until they become established. If infested with red spider the plants must be kept well syringed until they are clean.

Chrysanthemums.—The early varieties whose buds are forward should now be removed to a cool, airy house; others should be kept regularly tied and made secure against stormy weather. Houses required for Chrysanthemums and other greenhouse plants that have been stood outdoors for the summer should be cleaned and prepared for their reception. The glass should be washed down and all wall surfaces given a coating of linewash. The best medium for making this fast is skim milk. All permanent shading should now be washed off, as it is very essential that plants should have all the light possible, and in a general way there is far too much shading used.

Tritonia crocata, of which there are quite a number of varieties, is very beautiful and useful

for the cool greenhouse, and it is surprising they are not more generally grown. Like most South African bulbs, their growing season is during our winter, and they succeed under the same cultural conditions advised for Freesias and may be potted up any time during this month. The corms are

small, and six or eight should be put into a 48-sized pot. They can be grown in cold frames until they show their flower-spikes during the spring, when they are best removed to a cool greenhouse. J. COURTS.

Royal Botanic Gardens, Kew.

THE CULTURE OF SWEET PEAS

THE art of growing Sweet Peas has now been brought to great perfection, and those who desire to exhibit should be prepared to spend a good deal of time over them in order to ensure success.

This applies to fruits, flowers or vegetables, so that Sweet Peas are no exception to the general rule. In olden times the general custom was to sow Sweet Peas in mixture in the form of hedges, or much the same as for garden Peas, and even now one may see them so grown occasionally in rural gardens. This plan does not allow individual varieties to show what they are capable of doing, because the strong-growing varieties cripple or suppress the weaker ones. It was not till the late Henry Eckford began to sow the varieties separately and to evolve fine new ones that the Sweet Pea showed what it was capable of doing for the beautifying of gardens.

WHEN TO SOW.

Where the soil is suitable, Sweet Peas may be sown in the open at the beginning of March, and again in October or November to stand the winter and flower early. Both these plans have been superseded, whether the object is for exhibition, for adorning the garden or for home decorations. Skillful growers now sow the seeds in 5in. pots and place them in a cold frame, to be kept close till the seedlings appear and then gradually ventilated. The best time to do this for the southern half of England is from October 7 to 14. Northern growers should sow a little earlier. As soon as the seedlings are well established the lights should be drawn right off every day, except during heavy rain and hard frost or snow. In gardens that are badly infested with sparrows, it will be necessary to lay netting over the frames to keep these marauders at bay. During mild weather the grower who is on the alert will occasionally examine the frames for slugs.

The next best time to sow, perhaps, would be at the end of January or beginning of February, and at this period of the year it will be necessary to give them gentle heat and keep them as near the glass as possible. As soon as they are well up, the seedlings will require judicious ventilation and weeding, for most soils are more or less full of the seeds of weeds.

PREPARATION OF THE SOIL.

If only one long row is to be sown, the soil should be trenched 3ft. wide and deep, well manuring it at the same time. Where several rows are intended, the whole of the soil should be trenched to this depth and well manured between the different spits. Where the sub-soil is very heavy this should be well broken up and manured, to ameliorate it and enable the roots to penetrate freely. Deep working of the soil adds greatly to its water-holding power in summer, for Sweet Peas must have a continuous supply, or growth will get checked during the first period of drought. Each trench should be laid up in the form of a ridge at the top to expose as much of the soil as possible to the action of frost and rain, which crumble down stubborn soils to the powdery condition favourable to growth. When trenching has been finished, sprinkle the soil equally all over the top with slaked lime. In old gardens that have been manured for a long series of years so that the soil is black with decaying vegetable

matter, it is advisable to throw out the soil from the trenches in autumn and leave it exposed to the sweetening influence of the elements. It should be replaced in February or March.

PLANTING.

In light and friable, well drained soils planting may be done during the third week of March. Where they are heavy and not in suitable condition for the operation, planting should be delayed till a more favourable time. It has been done with success as late as May. Cut a trench of suitable depth, with the spade, alongside the garden line. Turn the plants out of the pots, shake away the soil, disentangle the roots, set the plants alongside the straight edge of the furrow, place some of the finer soil over the roots, then some of the rougher material and tread it firmly. Fill in the rest of the soil, make it tidy and put some small twigs against the plants to keep them upright. Something should be done at this stage to frighten birds away, otherwise it may be found that they have ruined many of the plants at the first opportunity. Green and tender plants put out where nothing was growing before have a great fascination for the destructive sparrow. Even where sown outdoors, Sweet Peas in some gardens get regularly pinched by these marauders. Black cotton, elevated about 3ins. above the soil on pegs, on either side of the row, is usually very effective. Tinkling pieces of tin or glass, suspended on sticks, are sometimes employed.

AFTER-TREATMENT.

Early support must be given, whether that consists of bamboo rods, stakes or Simplicitas netting. Either one of these must be made secure against wind, for it must be remembered that the wind has a great power on the side of a row when the plants are 4ft. to 8ft. or more high, and just when they are at their best it may be. Most growers know the capabilities of their soil in giving height to Sweet Peas, and should make provision accordingly.

When sown in October, the plants will make a number of shoots more than is necessary or desirable, and these should be thinned to two or three of the best, the remainder being pinched, as well as others that may subsequently arise. This should be done when the shoots have grown to a height of 9ins. to 12ins. The selected shoots should be tied to the stakes, but not too tightly. Some room should be allowed for the thickening of the stems. If grown especially for exhibition and the show does not occur till late in the season, some growers pinch the shoots in June, or at least six to seven weeks before the exhibition, to retard them. Only one shoot should be taken up from this pinching, all the rest being stopped.

Hoe the ground once a week whether it seems to require this or not. Hoeing has other purposes to serve besides keeping down weeds. In dry weather it serves to conserve the moisture, and in moist weather it sweetens the soil, and at all times allows freer access of air to the roots. Mulching is sometimes advisable in prolonged drought, but it is best to keep the hoe going as long as possible. It is often necessary to give copious supplies of water during dry weather in order to keep the plants growing steadily and vigorously to get length to the flower-stem and size to the blooms, as well as colour.

If a sufficiency of farmyard manure was unobtainable at planting-time, it will be necessary to use artificial manures. These may consist of proprietary or general fertilisers. Potash and phosphates are suitable for Sweet Peas. Whatever is used, it should be applied in small doses and often. Clear soot water makes a good stimulant, but this should never be strong. Weak liquid manure is also a safe one to use, always well diluted. Overdoses of anything are harmful, or even ruinous in some cases. After every watering or application of manures that necessitates watering, the soil should be hoed the following day. During the evenings of warm days it proves refreshing to the plants if they are sprayed with water that has been exposed to the air for twenty-four hours.

VARIETIES TO GROW.

Out of the hundreds of varieties available it is difficult to make a selection of the best for any particular purpose and yet keep within the limits of space available. There may be differences of opinion, but for exhibition the following selection is in all respects worthy: Mrs. Tom Jones (blue), Renown (carmine), Royal Scot (cerise scarlet), Picture (deep cream pink), Charity (crimson), Warrior (dark maroon), Tangerine (orange), Gloriosa (orange scarlet), Jean Ireland (picotee edge on cream), Royal Purple (deep purple), Hawlmart Scarlet (bright scarlet), Edna May Improved (white), Felton Cream, Royal Salute (deep cerise), R. F. Felton (lavender), King Mauve (mauve), Annie Ireland (picotee edge on white), Hawlmart Pink (deep pink), Sunset (rose) and Barbara (salmon). If it is desired to limit the above number, the first twelve may be grown. All the above may be grown in the open garden, without shading, except Tangerine and Barbara, which are liable to burn in bright sunshine, and should be shaded. There are other distinctive colours in the Sweet Pea, but the above are among the most telling.

For garden decoration and cut flowers, light and pleasing, but distinct and telling colours should be selected. The following, among others, are distinct, free flowering and vigorous: Mrs. Tom Jones, Royal Salute, Royal Scot, Charity, Jean Ireland, Royal Purple, Picture, Hawlmart Scarlet, Market Pink (deep pink), Helen Pierce Spencer (marbled blue), Rosabelle (deep rose) and Constance Hinton (white). J. F.

The False Lupin.—A plant that has been designated "False Lupin" on account of its flowers resembling those of *Lupinus arboreus*, *Thermopsis montana* syn. *fabacea*, is a most attractive and useful plant for planting on the margins of shrubbery borders. It grows from 2ft. to 3ft. high. It should be planted where it can remain undisturbed and will quickly establish itself. Its palmate, downy leaves and numerous bright yellow pea-shaped blossoms in terminal clusters are very attractive in the shrubbery. It may also be planted in partial shade, such as under the shade of tall trees, and is a recommendable plant for London gardens. It flowers during late spring and early summer.

Horticulture and the Hospitals.—The South-gate Allotments Federation is organising a Fête in aid of the Royal Northern and Passmore Edwards Hospitals, which will be held in Broomfield Park, Palmers Green, N., on Saturday, September 16. The Horticultural Section promises to be most successful, no less than five challenge cups being available for competition. The exhibition fee is 1s., which includes admission to the Fête and entrance fee to any two classes. Particulars and entry forms are obtainable from the Hon. Secretary to the Horticultural Committee, Mr. J. T. Chilvers, 81, Selborne Road, N.14.

BARR'S Beautiful New Seedling NERINES

The most beautiful and easiest grown of Autumn-flowering Bulbs for the Greenhouse.

For autumn decoration in the greenhouse few plants can compare with Nerines for their brilliant and attractive colours. The flowers, which are produced in umbels of 6 to 24 blooms, are borne on stout stems varying in height from 1 to 2 feet. In colour they range from dark red, vivid crimson, cerise and scarlet to salmon, coral-rose, pink, blush and white, many having a glistening lustre which in sunlight gives them the appearance of being dusted with gold or silver. They remain decorative for many weeks, and their beauty may be enjoyed in a sitting-room as well as the greenhouse, if the pots are kept in a sunny window.

12 in 12 beautiful named varieties .. 42/-, 50/-, 63/- and 84/-

AUTUMN COLOUR IN THE SHRUBBERY

AS autumn progresses the herbaceous border tends to become "draggle-tailed" and the rock garden shews to small advantage, so that the principal effects must be looked for in wild garden and shrubbery. Even here, however, forethought must be used if really good results are to be obtained.

Colour among shrubs and trees at this season is obtainable in flower, fruits and foliage. Late-flowering shrubs are comparatively few in number but, fortunately, excellent in quality. During September and often in October the varieties of *Buddleia variabilis* with immense panicles of purple or almost violet pleasingly fragrant flowers with orange throats are, if not at their best, still brilliant. The best known varieties are *Veitchiana*, *magnifica* and *Wilsoni*. The first named is the first to flower and the palest in colour. Of the three, *magnifica* is the deepest in colour, the latest and has the largest panicles, but *var. superba*, less often seen, is later still and quite as large in panicle, these being a little "fatter" and more blunt ended than in *var. magnifica*. The Spanish or Rush Broom, *Spartium junceum*, often provides welcome golden colour in September, as do many of the *Ceanothuses*, particularly *C.C. azureus* and *americanus* and their hybrids, notably the beautiful *Gloire de Versailles*, perhaps the longest flowering of all. Four rather uncommon *Escallonias* provide useful autumn blossom, namely *E.E. exoniensis*, *organensis* and the two somewhat similar white varieties, *floribunda* and *montevideensis*. The late-flowering *Hydrangea paniculata*

or its all sterile-flowered and very distinct variety *grandiflora* is to be found in most shrubberies, but *Hydrangea arborescens grandiflora* is less well known though quite worthy. It really requires and well repays a little staking as otherwise the shoots prove too weak for the heavy flower heads which, especially in wet seasons, crowd towards the ground.

The abutilon-like forms of *Hibiscus syriacus* are genuine autumn bloomers. They have, however

fragrant. Not over hardy, it should be given a fairly sheltered position.

The Venetian Sumach or Smoke Bush, *Rhus Cotinus*, with its persistent fluffy inflorescences, is one of the ornaments of the autumn garden. The inflorescence, which is largely sterile, is pinkish at first, afterwards turning a smoky grey. It is exceedingly effective when massed.

Two *Magnolias* continue to produce blossoms until far into autumn and though there are never sufficient open at one time to make a display their exquisite chalice give dignity to the shrubbery. One species is the Swamp Bay *Magnolia glauca*, with deliciously fragrant flowers, gins, or so across, either pure white turning buff with age or creamy, also going off deeper in colour. This is a rather variable, more or less deciduous species with foliage glaucous and downy beneath. It attains, at last, the stature of a small tree. *Magnolia grandiflora*, the other species, sometimes called the Laurel Magnolia,

THE SMOKE PLANT (*RHUS COTINUS*) IN AUTUMN.

several drawbacks, such as the rather stodgy shape of the bushes and the not too interesting foliage, the unpleasing colouring of most of the varieties and above all their unwillingness to flower freely except after a warm and moderately dry summer. These defects notwithstanding, the white varieties at any rate are worth growing. Another purely autumn flowering shrub is that sometimes called the "Blue Spiraea" (*Caryopteris Mastacanthus*). The trusses of bloom are of a moderately deep but rather cloudy blue and the foliage is

a larger growing and evergreen and takes some years to produce blossom. The flowers are often as much as roins, across, however, and very fragrant. There are many varieties, of which perhaps the best is known as *gloriosa*, though the *Exmouth* variety (sometimes called *lanceolata* or *exoniensis*), figured in *THE GARDEN* for September 2, page 438, is very fine also. In the North this tree is generally grown against a south or west wall. It is hardy, but liable to be broken by falls of sticky snow.

THE AUTUMN BLOOMING HIBISCUS SYRIACUS.

FRUITS OF A HYBRID CHINESE BARBERRY OF THE WILSONÆ SECTION.

CLANOTHUS GLOIRE DE VERSAILLES WHICH FLOWERS FROM JULY UNTIL SEVERE FROST.

For the fronts of shrubberies the late and long-flowering Lead Plant, *Amorpha canescens*, is useful. Its panicles of purplish flowers are often a foot long. That quaint leguminous shrub *Indigofera Gerardiana* (like the hardy Fuchsias, it is only sub-shrubby in the North) produces its pea-like rosy purple flowers until well on in autumn and should not be overlooked when ordering. Mention of the hardy Fuchsias calls to mind their very special merits for our purpose. *F. macrostemma*, with several closely allied species or (probably) forms, such as *corallina*, *globosa* and *gracilis*, and the stouter but less free to flower *F. Riccartonii*, are the hardiest, but the beautiful rose and white hybrid, *Mme. Cornelison*, is worthy of trial.

Many of the varieties of *Veronica speciosa* flower well into autumn, including the beautiful crimson *Simon Delaux*, but these are hardy only in favoured localities. *Veronica angustifolia* with long racemes of white flowers is hardier and there are many similar, probably hybrid, forms which are also autumn-flowering. Short in the raceme, but of a glorious purple colour is the rather prostrate mongrel sort called Autumn Glory, which again crosses freely with *V. angustifolia* and others to produce useful autumn-flowering varieties.

Quite a number of Heaths flower at the "back end," these including the Cornish Heaths, *Erica vagans* (several varieties), the Cross-leaved, *E. Tetralix*, and varieties, *E. ciliaris* and its variety *Mawiana* and the hybrid between this species and *E. Tetralix* (*Watsoni*), as well as *E. Mackaibii*, which comes very near to *Tetralix*. The Irish Heaths, *Daboecia polifolia* also flower well in autumn, especially the loose-growing, lantern-flowered varieties usually listed as *D. p. var. globosa*.

The shrubby Cinquefoil, *Potentilla fruticosa* and its many varieties are useful for the fronts of shrubberies. The typical plant bears butter yellow flowers, but there are varieties with flowers of almost every shade from pure white to the typical colour. The *Romneyas* are, of course, excellent for autumn flowers, but they make but a comparatively poor show in such a season as the present. The water-loving Sweet Pepper, *Clethra alnifolia*, with its spicy fragrance and the similar but rather later flowering *C. tomentosa* are valuable as late-flowering shrubs.

Other late-flowering shrubs are, generally speaking, either not conspicuous—such as for example, *Clerodendron*, *Fatsia* and *Hamelis virginica*—or not reliable, such as the larger *Yuccas*, which flower but seldom and then not always in autumn. The garden hybrid Clematises provide, however, a feast of colour in early autumn if allowed to ramble on the branches of trees and shrubs.

Coloured fruits should play a larger part in garden decoration than they do at present. The Barberries alone have fruits of many sizes with great diversity of shape and a remarkable range of colour, varying from bright clear coral, through bright red to crimson, deep purple and black, some covered with white or purple bloom, some smooth and clear as the hips of the Dog Rose.

The Conion Barberry is one of the most effective tall species and the purple-leaved form seems equally as fruitful as the green, though with the former one misses the brilliant autumn foliage colour associated with the typical plant. *Berberis Thunbergii* has rather similar berries less freely produced, but the added glory of the autumn-tinted foliage more than compensates for this. In good soil in full sunlight this shrub is for a few weeks, before the fall of the leaf, easily the most beautiful thing in the choicest shrubbery. *Berberis polyantha* is especially effective when roped with berries, but now we come to the great group of intensely spiny Barberries from the "Roof of the World." These are all beautiful and distinct enough when side by side, but difficult to differentiate in an article. There are *Wilsonæ*, *subcaulata*, *brevipaniculata*, *Prattii*, *dictophylla* (a little of the *vulgaris* or *Thunbergii* appearance lurks in this), and *Stapanna*.

Berberis Darwinii and its hybrid with *B. empetrifolia*—*B. stenophylla*—are very beautiful when laden with their deep purple fruits but, unless cottoned, the birds soon clear them.

The Cotoneasters are largely grown for autumn effect, mainly of fruit, though *C. horizontalis* is worth growing for foliage colour alone. *C. microphylla* hides its berries with foliage when grown as a bush. It is at its best growing over a wall, but is more apt than most to become busy.

(To be concluded.)

THE INVALUABLE DELPHINIUM

Its Culture, Use, and a Selection of Varieties.

WHEREIN lies the admitted charm of the Delphinium? It has no particular beauty of foliage; it does not continue overlong in bloom, although it is true that by cutting out the central spike as it passes, the flowering period may be somewhat prolonged; it does not wreath itself in blossom like, let us say, *Lavatera Olbia*—indeed, under average cultivation the length of the flower-spike is but a small fraction of the total height of the plant. Wherein, then, lies its charm?

To the writer the perennial Larkspur in its best forms has two great claims to popularity. In the first place, its spiry, erect, yet not stolid habit of growth makes it invaluable for providing very necessary variety of outline either in the herbaceous border or among round-headed flowering shrubs. Secondly, it provides a wide range of blue shades, which, after midsummer, are all too scarce among hardy flowers.

To obtain Delphiniums at the best, pains must be taken with their culture. In a dry season on shallow, undercultivated soil the spikes will be distressingly short and crowded, and the plants themselves dwarfed and miserable. In a wet, draughty season there is always the bugbear *mildew* to contend with. Sort, sappy growth obviously conduces to mildew. It follows, then, that soil for Delphiniums should be cultivated as deeply as practicable and well enriched, but not excessively, as regards nitrogenous manures. Bone-meal and, on loose-textured soils, a little basic slag should be included. Two ounces to the square yard is a fair dressing of a "slag" containing 22 per cent. soluble phosphates. The soil should be quite settled and solid before planting takes place. Whatever precautions be taken, it will certainly be desirable to apply water during prolonged drought, but one really good soak and a mulch will under such favourable conditions go a long way.

Two-year plants, that is, those which have been established one year, generally give the best results, but three and four year stools should answer perfectly if the growths are thinned when six to nine inches high. Incidentally, such sucker growths make admirable cuttings for increasing stock. Whatever the precautions in the way of good cultivation, mildew will appear most seasons, and the conditions under which these plants are usually grown make spraying, whether wet or dry, a virtual impossibility. Some varieties are especially prone to mildew and should be avoided, however desirable they may appear in other ways. Needless to say, none such is included in the short

list of varieties which concludes these notes.

If Delphiniums seem called for in a draughty corner where mildew would be likely to make itself especially obnoxious, it is best to rely upon plants raised from seed, which have, in the nature of things, more vigour and so resist the attack of the fungus better. Raising Delphiniums from seed is an interesting process, and it is remarkable how many seedlings seem, to the amateur, better than standard named varieties. Many a novice

BRIGHT BLUE, WHITE CENTRED—DELPHINIUM COLONEL SIR WYNDHAM MURRAY.

has thought that in a few scores of plants he had an army of new sorts which would revolutionise everyone's ideas of the Delphinium. Alas! after propagation the swans turn out but very ordinary geese after all, and quite inferior to the named varieties they seemed so much to excel!

All this, however, detracts not at all from the value of these seedlings as border plants, especially when it is remembered that by purchasing or saving seed of some good variety, say, Rev. E. Lascelles, for instance, the bulk of the seedlings will closely resemble the parent as regards general colouring. A few rogues can, after all, be readily weeded out. Nor is it necessary in many cases to select them to colour, for the Delphinium has this merit—that considerable as is the colour range (and different flowers contain almost every shade of blue-purple, whether strong or diluted as well as almost pure blue, pink and white, "clashing" is unknown.

It has hitherto been assumed that the Delphinium is what is commonly called a "blue" flower, but there are, of course, sorts with flowers of a shade of dirty ivory and one with blue-white flowers (Moerheim). The ivory-white sorts are frankly unacceptable. Moerheim is better, though its flowers tend to become a washy lilac in wet weather.

Were it not so, however, it is very doubtful if we want a white Delphinium. There is, after all, no shortage of white flowers. Indeed, many gardens look "cold" because white is employed to excess. Of white shrubs the name is legion. Among herbaceous plants there is certainly no shortage. We get white in *Chrysanthemum maximum*, *Verbascum*, *Hollyhock*, *Galega*, *Phlox*, *Malva*, *Sidalcea*, *Campanula*, *Anthemis* and a host of other common plants beside Lilies, *Asphodel* and *St. Bruno's Lily*. No! Of the two outstanding virtues of the Delphinium one is missing in the white sorts.

The propagation of named Delphiniums consists in dividing up the clumps periodically and in striking cuttings taken—detached with a trace of "heel"—from the stools in spring. These latter, which usually make the best plants, should be about six inches long and should be inserted in gritty soil and kept just sufficiently close to prevent flagging until rooted. A little bottom heat is beneficial and tends to hurry up what is otherwise rather a tedious process, but it must be slight or the constitution of the young plant will be enfeebled. Seed may be sown either as soon as it is ripe or about the shortest day. Ordinary seed compost is suitable, but boxes or pans are preferable to prepared beds in frames, since slugs have a great predilection for Larkspurs (both annual and perennial). The seedlings grow quickly and should be pricked out before they become drawn and weakly. They may go into their permanent quarters in autumn and should flower gloriously the following summer.

Slugs by no means confine their attention to the tiny seedlings. In old slug-infested gardens they not infrequently, by repeated grazings, entirely destroy full grown plants. This pest must certainly be kept in check if Delphiniums are to be a success. A temporary but often successful measure is to sprinkle soot, or soot and lime, around the crowns from early spring until the growths have lengthened considerably, but the elimination of such slug-harbours as box edgings and dressing the land when bare with an approved soil fumigant is at once more effectual and permanent. No! should the use of a large pair of scissors after a shower be considered unworthy.

From so many varieties it is not easy to make a selection, but the following, if not "the best," are all excellent: Rev. E. Lascelles, royal blue, white centred, 5½ ft.; The Alake, deep violet blue, 5 ft.; Queen Wilhelmina, a splendid pale blue, 4 ft.; Persimmon, "Belladonna" colour, 3½ ft.; Mrs. Thompson, clear blue, 4½ ft.; J. S. Brunton, almost sky blue, light and elegant and good for cut flower, 4 ft.; Lizzie van Veen, Cambridge blue, 6 ft.; King of Delphiniums, rich blue and plum colour, white eye, 5 ft.; Henri Moisson, deep purple, black centre, 4 ft.; Colonel Sir Wyndham Murray, bright blue, white centred, 6 ft.; Lorenzo de Medici, a remarkable variety, soft blue, pink shaded, 5 ft.; Statuaria Rude, pale heliotropic, magnificent, 6 ft.

Of recent novelties the best is unquestionably the tall and handsome Milliecut Blackmore, a pleasing shade of blue-naive, black centred. For nearer the front of the border and for grouping alone in suitable positions, the old Delphinium *Belladonna* is still unsurpassed. The plant called *Belladonna semi-plena* is also useful for the same purpose, so are Persimmon, already referred to, and Capri, of almost sky-blue colouring.

THE MUCH-ABUSED CONIFER

IN the following notes only species and varieties will be mentioned which are suitable for gardens of moderate size, say not exceeding three or four acres in extent. Some, of course, are suitable for gardens even smaller in size. The conclusions arrived at, representing as they do the writer's personal experience, mainly on a light sandy loam overlying gravel and practically lime-free in a Midland garden, are necessarily imperfect. A writer with experience of the south-west of England or the corresponding corner of Scotland, would no doubt have different ideas as to the relative values of species, but the climate and soil of this Midland garden may be taken as fairly typical of very extensive areas in South Britain.

In considering the various genera of coniferous trees, we will commence with the Cupresses, not because they are especially beautiful or interesting but because they are almost universally planted in small gardens to the exclusion of many really beautiful trees. The Cypress family is divided into two great divisions, the Cupresses proper and the so-called White Cedars (*Chamaecyparis*), which includes Lawson's Cypress (*Cupressus Lawsoniana*) in all its many forms, *C. obtusa*, *C. pisifera* and *C. nootkatensis*, each with several interesting varieties.

Cupressus Lawsoniana in anything approaching its typical form is a rather funereal tree of no special beauty of habit or colour, but some of the varieties are certainly beautiful. The very columnar and rather glaucous *Fraseri* is one. *C. L. Alluni* is rather bluer but less elegant of habit, while *Triomphe de Boskoop* is bluest of all, but is in habit very similar to the typical "Lawson." Less often seen than any of these, closely fastigate, singularly rigid of habit and small foliaged, is the variety *Wisselii*, with rich deep green foliage. This is a very distinct and handsome, though by no means solid looking tree. The much planted *ere ta-viridis* is hardly satisfactory in the Midlands

or North as snow is apt to mar its beauty. Elsewhere it needs using with discretion or its rather "Noah's Ark" formality may ruin the garden picture. There are variegated and golden colour variations of this, only mentioned as best avoided. *Cupressus Lawsoniana lutea* is an admirable close-growing golden form, perhaps a little more columnar in habit than the typical plant. *Stewarti* has paler yellow foliage and a more spreading habit. It is faster growing than *lutea* and makes a handsome tree. For those enamoured of variegation, the variety *albo-variegata* is recommendable.

Cupressus obtusa is also a variable species and one not seen in gardens as frequently as it might be. The typical form is quite good, while there are fine golden forms, such as *elegans* (not often seen), *Crippsii* and *densa aurea*, the last two somewhat alike. *Lycopodioides* and *tetragona aurea* are quaint and beautiful dwarf forms suitable for rockery or front of the shrubbery border. There are several miniature *Retinosporas* which are in fact only forms of *C. obtusa* which have failed to change their "baby coat" for the adult sail-like foliage. *Cupressus pisifera* is a broad-based shrub which, with its useful golden form, has been planted far too freely the last fifty years. It takes up a good deal of ground as it is much more spreading in habit than the Lawsons. Varieties of this are those so-called *Retinosporas plumosa*,

THE FINE INCENSE CEDAR *LIBOCEDRUS DECURRENS* AT FROGMORE.

plumosa aurea and *squarrosa*, the latter with pretty blue-grey foliage, but all with the spreading habit of the typical plant.

The Nootka Sound Cypress (*C. nootkatensis*), often still listed as *Thuyopsis borealis* is a more gracious and shapely tree than *C. Lawsoniana*. There is a very pleasing colour form in which the young foliage is pale gold and another (*pendula*) in which the branchlets droop from the main branches, giving the tree a most distinct and noteworthy appearance.

The true Cupresses are not often seen in small or suburban gardens. They are emphatically trees for the Midlands and South, as even the hardiest will not withstand the rigours of our Northern winters. Their lack of popularity is largely due, however, to the fact that except as small trees from pots, they transplant badly. To counterbalance this, however, they for the most part grow rapidly and are far more beautiful than the White Cedars. The commonest species is *C. macrocarpa*, much used in Southern England as a hedge plant and wind screen. The best and most upright form of this is called *fastigiata* and this form has a beautiful soft yellow counterpart called *macrocarpa lutea*. Somewhat similar to *macrocarpa* but glaucous in tint is *C. sempervirens*, the Italian Cypress, of which there is a very fastigate form (*fastigiata*), and a more spreading one (*horizontalis*). This seems quite hardy in the South Midlands once established, but a severe winter is apt to play havoc with young trees. Hardier than the foregoing, similar in colouring—perhaps a little brighter though—and more spreading is *C. arizonica*.

For open spaces as specimen trees there is nothing to beat the stately Incense Cedar, *Libocedrus*

A MAGNIFICENT CEDAR.

decurrens, often listed as *Thuja gigantea* in nurseries, though *Thuja plicata* (Lobbi), a quite different and inferior tree, is often sold as *T. gigantea* also. The effect produced by the Incense Cedar is often aimed at by those who, for want of knowledge, plant *Cupressus Lawsoniana erecta-viridis*, which is not really satisfactory when adult.

There are many varieties of the Arbor-vite, *Thuja occidentalis*, some of which are valuable for the browns and russets of their "winter dress." Variety *lutea* is a very good one in this respect. Var. *Vervaneana* is a pleasing garden pyramidal conifer which turns brown in winter. Unfortunately it loses its colour on some soils. *Thuja orientalis* (Chinese Arbor-vite) is not too hardy, so should not be used in Northern gardens. In its better and more compact form it is a handsome tree. *Thuja plicata* is a distinct and useful shrub though, as already stated, a poor substitute for the Incense Cedar. The best form is the tall columnar one known as var. *pyramidalis*.

The Cedar needs space for development and time for growth to be effective. Consequently of the

three species only the Deodar (*Cedrus deodora*), which is beautiful as a young tree, is nowadays often planted. There are several varieties of Deodar, but the typical plant from seed is likely to make the handsomest tree. The magnificent Cedar of Lebanon needs no description, but should be more often planted. So should the Atlas Cedar (*C. atlantica*) and its beautiful blue-grey variety *C. a. glauca*. Most upright growing of Cedars, *C. atlantica*, may be used to form a little grove to accentuate a hill-top or to form a screen.

PANDANUS-LEAVED PLANTS

Under the above title the writer discusses the merits and uses of such plants as the Pampas Grass, Yuccas, Torch Lilies, etc.

As seen in many gardens, the Pampas Grass is a pitiable object, not because it is badly grown, but because it is ill-placed. For this reason many people of taste and discrimination are now leaving it out of their garden scheme entirely. If they have any extent of ground at disposal, this is a mistake.

Plants of the formal, certainly exotic and probably somewhat tropical appearance of the Pampas Grass look best grouped together. It is a good idea to devote the borders

SMALL BUT DISTINCT AND BEAUTIFUL, YUCCA ANGUSTIFOLIA.

A STately NEW TORCH LILY—KNIPHOFIA C. M. PRICHARD.

enclosing a grassy vista almost entirely to the culture of such plants. The Torch Lilies will make there a show of brilliant, but pleasing colour in the summer months, reinforced, it may be, with creamy *Yucca filamentosa* and *flaccida* at least may be relied upon to flower year by year.

Later in the year the various pink and snow white Pampas plumes produce an entirely different but quite beautiful effect and even in winter, at least in our warmer counties, the various but harmonising foliage gives pleasure to the eye. Further north it is necessary to tie up the leaves of all three genera to prevent snow-broth from reaching the crowns and, by alternately freezing and thawing, destroying the plants. Even here, however, there is great practical advantage in having all the plants together. The front of such borders is an excellent place to display the late-flowering, all but scarlet, *Schizostylis coccinea*.

Springtime need not see such borders entirely bare of colour, for spring-flowering bulbs may readily be introduced towards the front. From the point of view of effect it is better to group one or two classes of plants at each season in each separate section of the garden, since vistas which are more or less a repetition one of another, even though not "spotty" in themselves—which they are apt to be—become, after a while, wearisome to traverse.

White is easily supplied when the Torch Lilies flower by the use of various White Lilies, such as the beautiful White Martagon or even the Madonna Lily (*L. candidum*), but blue is not readily introduced. The Delphinium is the time-honoured plant for the purpose but, despite its aspiring habit, its foliage is scarcely suitable for such a position. Some of the tall-growing but short-hyed *Echinus* would be more suitable. Soft yellow may be introduced into the background by employing that stately Mullein Harkness's Hybrid; but if the brilliant colouring of the *Kniphofias* is properly led up to few will find the effect need softening.

There are now many excellent varieties of Pampas Grass which are immense improvements on the too often dirty-coloured seedling forms, sold simply as "*Cyperium argenteum*." One of the earliest to flower, rather erect of habit and dark of stem and foliage is the rosy *Rendatleri*. An early and very beautiful white sort is called *Bertini*, while for later in the autumn there are *Rene des rouges*, *Rene des roses* and the giant silvery-plumed *Monstrosa*.

The pink forms do not long retain their colour, unfortunately, so that the silvery-white ones should be more freely planted. In Northern gardens, the late forms are spoiled by frost before they can display their beauty, so should be omitted. Indeed in the North it might be well to combine one's attention to the very ornamental *Arundo*

conspicua, to the casual eye very like the true Pampas Grass and much earlier to flower.

The list of Torch Lilies grows longer year by year and some of the newer introductions are extraordinarily beautiful. An especially beautiful new yellow sort with towering spikes is called C. M. Prichard. Yellow sorts may now, in fact, be obtained to match in stature such red giants of the family as *Kniphofia aloides* (U'varia) nobilis, which in congenial situation will reach 8 ft. to the top of the spikes. T. a. grandis is similar. T. aloides præcox is free-flowering and very early, often commencing to flower in May, but it lacks the dignity of the later sorts.

Some of the *Kniphofia* species are very interesting and have especially beautiful foliage. There is, for instance, the sub-shrubby group, of which the species form a distinct permanent stem as do most Yuccas. The best known of this section is *K. caulescens*, a happily named plant as this species produces spikes which do truly resemble the colouring of a poker heated beyond redness. As the flowers age, moreover, they change to a greenish yellow colour not unlike the straw-yellow of highly heated steel. The colouring of this plant is too harsh for the mixed flower border and even in the Torch Lily walk it is well to associate it with the soft yellow species and varieties. The glaucous foliage is, however, very distinct and beautiful.

K. Northie is nearly related to *caulescens* and has the same habit of growth, but its flowers are pale yellow tinged with red at the tips. *K. Tysoni* is another belonging to the same section, of rather less harsh colouring than *caulescens* and of stouter, more robust habit. Its only questionable point is its comparative hardiness.

Of the hybrids, the giant yellow forms are most interesting as being more recently obtained. Such are Star of Baden-Baden, a giant with straw-yellow spikes; Lachesis, deep yellow, less stately but more prolific; the orange-yellow Ophir and the magnificent Obelsk, with golden-yellow spikes. The brilliant John Benary is a well known crimson and deservedly esteemed. Many of the apricot and coral shaded hybrids have *Leichtlini* or *pauciflora* blood and are so less hardy than the sorts already mentioned. They are, none the less, beautiful for the fronts of borders. Where dwarf but hardy forms are wanted there are *K. Macowanii* and its taller hybrid *corallina*, also the rather coarse and "stubby" *rufa*.

The shrubby Yuccas are hardy only in the South and South Midlands of England, except near the sea coast, but *Y. filamentosa* and the closely related *Y. flaccida* seem quite hardy everywhere. The handsomest species, *Y. Whipplei*, is also the most tender, but the magnificent if rarely flowering *Y. gloriosa*, of which there are at least three distinct forms is hardy even in the North if snow and winter rain be kept from the crowns. Hardier still, but also requiring protection for the crowns in the North, is *Y. recurvifolia* which, almost as handsome, flowers far more frequently. The miniature *Y. angustifolia* seems about as hardy as *Y. gloriosa*. Its flowers are more open and less drooping than those of other species and the leaves are long and extremely narrow.

FORTHCOMING EVENTS.

September 19—Fortnightly Meeting of the Royal Horticultural Society.

September 20—Hertford Horticultural Society's Meeting.

September 21—National Rose Society's Autumn Show to be held at the Royal Horticultural Society's Hall.

September 23—Paisley Florists' Society's Show.

GLADIOLI AND HARDY FRUITS AT VINCENT SQUARE.

GLADIOLI again figured largely at Vincent Square, and on September 5 Messrs. Kelway and Son had a very fine exhibit of the best varieties. Most interest seemed to be centred in the sorts of brilliant colouring, and these certainly were grateful to the eye during the dull, sunless weather. The principal sorts were Colossal, J. W. Kelway, Star of Langport, Sir H. Talbot, J. L. Clucas and Nonpariel. The *Primulinus* hybrids are becoming very popular with exhibitors, and some exceedingly graceful varieties were shown by such growers as Messrs. Lowe and Gibson, Messrs. R. H. Bath and Mr. A. Edwards. The last named is a fresh exhibitor at the hall, and

hybrid tall *Lobelias*. Mr. F. G. Wood had a useful new Golden Rod in *Solidago* Ashstead Golden Spray. It is a fortnight earlier than Golden Wings, and has large branching heads of yellow flowers.

Suttons filled a large floor space with an enormous quantity of China Asters delightfully arranged. They had many colour varieties of Giant Comet, Giant French, Ostrich Plume, Mammoth and Victoria types, and also arranged large bowls of the highly decorative single-flowered varieties.

Shrubs were well represented in an interesting exhibit by Messrs. J. Cheal and Sons, who had various fruiting Crabs, shrubby Veronicas and

THE SOMEWHAT UNCOMMON COLLETIA SPINOSA WAS SHEWN IN GOOD FLOWER.

he arranged a very charming collection. The most attractive of the *Primulinus* varieties were Orange Brilliant, Yellow Queen, Valuta, J. P. Roen, Salmonea and Alice Tiplady. The finest Gladioli spikes were those of such sorts as Red Emperor, White Giant, Yellow Hammer and Pink Perfection in the exhibit by Mr. W. F. Gullick, while the collection of Dutch varieties by Mr. K. Velthuys was especially effective. The Foremarke Cup was awarded to Messrs. Lowe and Gibson for an interesting collection of spikes.

Mr. Sidney Morris showed a good selection of the *Monthrotias* in which he specialises. The outstanding variety was His Majesty, which has large, well shaped flowers of yellow colour heavily edged with dull crimson. He had other named sorts and a fascinating vase of seedlings.

The largest exhibit in the hall was that of herbaceous Phloxes and Delphiniums by Mr. H. J. Jones, and it was of such high quality and artistic value that he was awarded another gold medal. Border flowers generally were very interesting. In several collections there were vases of *Achillea Millefolium* Cerise Queen, of brilliant colouring. *Heleniums* were freely shewn, and prominent in a general collection by Messrs. B. Lathams, Limited, there were several valuable

Tamarix in flower, Maples of gorgeous foliage, the brilliant and curiously shaped fruits of *Euonymus latifolius* and some small pot plants of *Myrtus Luma* (*Eugenia apiculata*) profusely flowered. In the milder parts of the country this evergreen is quite hardy, and a glorious sight when smothered with its snow white flowers. Several Crabs, notably John Downie, were shewn by Mr. Charles Turner.

Several well-flowered sprays of that singular South American shrub *Colletia spinosa* were on view. Practically leafless, it bears its flowers on the spiny branchlets. The triangular-spined *C. cruciata* is a form of this species.

Roses were shewn in fair quantity by several growers, but there was no novelty of outstanding merit, nor is it to be expected at this season. Carnations were also very beautiful and of high quality. Clematises in a number of varieties and as plants in quite small pots bearing several flowers each were set up by Messrs. L. R. Russell, Limited, who also had brilliantly berried bushes of Firethorns and a most interesting collection of Bromeliads.

In view of the annual exhibition of the National Dahlia Society the next day, several growers, including the Dutch Dahlia Society, had fine

displays which will be found noted in the report of the Dahlia Society's Show.

Fruit was better represented than of late, and many visitors greatly admired the corner group of pot trees bearing bountiful crops of Pears and Plums. The perfectly trained fan-shaped Plums in particular evoked admiration. The chief varieties were Allgrove's Superb, upon which, after trial at Wisley, the Council confirmed the award of merit provisionally bestowed some time back. Jefferson, Althon's Gage and McLaughlan's Gage were also admirable, both on the trees and as generous dishes of gathered fruits in this fine exhibit by Mr. J. C. Allgrove. Williams's Pears and several Apples were also represented by fruits of excellent appearance.

Messrs. Daniel Brothers again had mounds of fruit and branches literally festooned with bunches of their September Black Currant. Not only is it a very late variety, but the flavour is all that could be desired, and the individual berries are as large as small Gooseberries. Mr. J. J. Kettle of Violet fame also shewed fruiting canes of his late Raspberry Lloyd George.

The Fruit Committee had several novelties to consider. Mr. T. Pateman brought forward a dish of a late Black Currant which he found in a Midland garden. It is a large well coloured berry of good quality, and the Committee recommended that it and Daniel's September be tried at Wisley next year. Messrs. Laxton Brothers brought several of their new fruits. Pear Laxton's Cropper has appearance to recommend it. It is a shapely fruit of medium size and pale yellow colour prettily flushed with rose on the sunny

side. The flavour is pleasant but not first class, but in view of its freedom it should be a good market variety. It was raised from Marguerite Marillat and Doyenné d'Été. Laxton's Supreme Plum is the result of a cross between Demaison's Superb and Victoria, and in appearance is a small pale red Victoria of good dessert quality.

NEW AND RARE PLANTS.

Centaurea Cyanus Silver Queen.—This is a silvery white variety of the well known Blue Cornflower and, no doubt, will soon become equally as popular as that elegant flower. Award of merit to Messrs. Barr and Sons.

Gladiolus Rt. Hon. Countess Beatty.—One of the most beautiful of the crimson-blotched varieties. It is a large spike of perfectly disposed widely expanded blooms. The lower segment has a large vivid crimson-lake blotch and the remainder of the flower is pure white. Award of merit to Messrs. Kelway and Son.

Primula Mooreana Improved.—In his book on the "Rock Garden" the late Mr. Reginald Farrer wrote that Primula Mooreana was quite the best of the varieties grown in gardens as Primula capitata, and with this there must be general agreement. The plant on shew was a distinct improvement, and carried numerous spikes of beautiful blue flowers on pulverulent stems. Award of merit to Lady Aberconway.

Streptocarpus Princess Mary.—Of late years there has been a great improvement in the large-flowered Streptocarpus hybrids. The colours are decidedly better, the blooms have more substance

and, what is perhaps most important, they are much more floriferous. Princess Mary is a splendid specimen of these improved giant Streptocarpuses. The rose-shaded flowers have a well marked straw-coloured throat. Award of merit to Messrs. R. and G. Cuthbert.

NATIONAL DAHLIA SOCIETY'S SHOW

THE National Dahlia Society have reason to be satisfied with their first independent show of recent years. In the old days this special flower society had big shows at the Crystal Palace and elsewhere, but of late, in common with so many other societies, it has had to be content with a smaller sphere. Although the sunless weather of the last few days was all against Dahlias opening their flowers freely, there were plenty of blooms of all types at Vincent Square on September 6 last, and their quality was decidedly the highest at any show. Such a wealth of gorgeous colour has rarely been seen in any flowers. Present-day Dahlias have gone very far from the original species which were introduced from Mexico in 1798, and it was exceedingly interesting to see the bunches of Dahlia Merckii, D. variabilis and D. coccinea which the Director of the Royal Gardens, Kew, sent to the Show. The influence of the soft lilac colour of D. Merckii was very evident in several of the new sorts, particularly

THE AMERICAN SPINDLE-TREE EUONYMUS LATIFOLIUS WITH BRIGHT ORANGE SEEDS AND CORAL BERRIES.

FINEST OF THE CAPITATA PRIMULAS, MOOREANA IMPROVED. FLOWERS VIOLET PURPLE.

in Mr. H. C. Dresselhuys, which was one of the selected varieties. In the magnificent collection from the Dutch Dahlia Society there was a most delightful bowl of it, and it harmonised well with the darker blooms of Prince of Wales and King Harold. This noteworthy exhibit of their newest sorts was the joint contribution of the chief Dutch raisers, and illustrated a number of other very handsome varieties of the large decorative type. Apple Blossom and Menr. Ballego were especially charming. Along the front of this imposing group, which received the Society's gold medal and won the unstinted admiration of all, there were several free-flowering sorts in quantity. Little Jewel and Chamois Rose were very graceful representatives of these small, dainty flowers.

The largest home-grown exhibit of Dahlias was set up by Mr. J. T. West, and it represented especially good varieties of the Decorative, Collarette and Single types. Of the first named, Victorine, Nancy, Blanche and the Prince were very prominent; while Judith and White Fox of the Collarettes, and Oberon, Dazzle and Malcolm among the singles were greatly admired in this gold medal collection.

Naturally, it was the dainty little Pompons that attracted most attention in the adjoining group by Mr. Charles Turner, as the Slough firm, although having a splendid general collection, have rather specialised in Pompons for many years. Messrs. J. Cheal and Sons are also very "strong" in Pompons, and such sorts as Phyllis, Daisy, Electra, Rufus, Little Beeswing and Garlie were very fascinating in both collections. Cactus varieties were especially noteworthy in an exhibit by Messrs. Carter, Page and Co., and of these Royal Sussex, Ivory White, Areturus and Paragon were perhaps the very best. Among their large Decorative sorts we admired Beauty, Ambrosa, Jupiter and Paul Crampel, which is almost identically the colour of the popular bedding "Geranium" of that name.

In the competitive classes Messrs. J. Stredwick and Sons took chief honours with the Cactus varieties; their sets of such sorts as Thos. Want, Valour, Supreme, Washington, British Lion and Sunbeam were well high perfect.

Mr. S. Mortimer still grows the Show and Fancy Dahlias admirably, and many visitors admired his superb first prize collections of Prince Bismarck, Standard, Arthur Rawling, Wm. Powell, Tom Jones and other sorts in the two classes. Messrs. William Treseder, Limited, were second in each case, and they won first prizes in several other classes, notably six blooms of Miss Stredwick Cactus Dahlias, six of the Show variety Arthur Harrison, six varieties each of Peony-flowered, Decorative and Collarette types. The large Collarette class was won by Messrs. Cheal and Son, who had splendid blooms of Cadet, Ustance, Diadem, Bonfire and such sorts. In this class Crimson Queen, Lilian and Peronne were also well shown. Messrs. Cheal and Sons were also first with admirable collections of Pompons, Singles, Garden Cactus and small Peony-flowered varieties, though the very best Pompons were in the amateurs' classes, where the first prizes were awarded to Mr. H. Brown and Mr. A. E. Barnes for wonderfully fine blooms.

NEW DAHLIAS.

Adorable.—This is a large, full-shaped Decorative variety. The broad orange-buff petals are tipped with white.

Arthur Bouquet. A robust-growing Decorative bloom borne on long, stout stems. The colour is a pleasing, warm orange-yellow.

Edith Page. A large-sized exhibition Cactus variety of star shape. The long petals are rolled, and their soft yellow colour is delicately flushed

STAR DAHLIA DORKING STAR.

THE RATHER COSMOS-LIKE SPECIES, D. MERCKII.

LADY GREER (PEONY-FLOWERED) AND LEONIE COBB (MINIATURE PEONY-FLOWERED.)

with pale coral pink when mature, so that it becomes a yellow-centred bloom.

Nectar.—This bright yellow Decorative variety of large size is of great merit.

Shepherdess.—A large, pure white Decorative variety of splendid form and borne on long, stout stalks. The above varieties were all shewn by Messrs. J. Stredwick and Son.

Dorking Star.—A pretty bloom of the highly decorative Star type. It is of silvery mauve colour with crimson rays in the centre.

Lady Greer.—This is a medium-sized Peony-flowered variety of fascinating rosy mauve colour.

Leonie Cobb.—A compactly formed small Peony-flowered bloom. The double row of rounded petals are of rosy-mauve colour, and the centre of the flower is dusted with golden yellow. This and the two previous varieties were shewn by Messrs. J. Cheal and Sons.

Protest.—A large Decorative variety of perfect form, borne on very long, stout stalks. The colour is an attractive shade of rosy mauve which is lighter at the tips of the florets. Shewn by the Central Gardens Supplies Company.

Crimson Glow.—This is a very beautiful small Peony-flowered bloom of vivid crimson shading. The petals are slightly incurved at the tips.

Marcella.—A dainty little Peony-flowered bloom of bright rose pink colouring.

Sophire.—A good white star-shaped small Peony-flowered variety.

Warrior.—This is a brilliant small Peony-flowered bloom of flattish shape and velvety crimson colour which is rather paler in the centre.

Zena.—A small yellow Decorative variety which is tipped with bronze. This and the four previous varieties were shewn by Messrs. J. Burrell and Co.

Border Perfection.—A handsome rich crimson-coloured, large Decorative bloom carried well above the foliage on stout stalks. This and the following varieties were shewn by members of the Dutch Dahlia Society.

Flambeau.—A large Decorative variety of bright brick red colouring.

Guineeltji.—This is a small Decorative variety of mauve colouring. It is almost a large Pompon in character, and seems to be very free flowering.

Jubilee.—This was perhaps the most uncommon-coloured variety in the Show. It is a good medium size bloom of the Decorative type, though the incurving narrow petals give it somewhat a Cactus appearance. It is beautifully shaded with lilac.

Mr. Dresselhuys.—A medium-sized Decorative variety of most beautiful rosy lilac shade which is paler at the tips of the petals.

Nelly.—The small, compact, rich crimson blooms of Decorative type are borne on almost disproportionately long stalks, though the variety would probably be ornamental in the flower border.

Misses G. Wurflein.—A very handsome, large Decorative variety of perfect shape. The colour is rich claret-crimson shaded velvety maroon in the centre of the flower.

Oranje Boven.—A beautiful orange-apricot coloured, large Decorative variety.

Prince of Wales.—Another large Decorative variety of similar shape but buff-orange colouring.

Richard Henckeroth.—This is a large Decorative variety of vivid scarlet colour.

Wake Up.—A white-tipped ruby-crimson Decorative variety of similar shape to the old variety Rosy Morn that was used for bedding-out purposes many years ago.

Zhr G. van Tebs.—A white Cactus variety which has broad petals and appears to have considerable garden value.

SOME IMPRESSIONS OF THE INTERNATIONAL SHOW AT GLASGOW

WHAT the Glasgow Corporation puts its hands to it does with the might of determination, and success seems to follow all its enterprises. The magnificent and states exhibition of flowers and fruit held in the Kelvin Hall from August 30 to September 2 was the joint production of the Corporation and the Glasgow and West of Scotland Horticultural Society, but it was also recognised in a very practical manner by the headquarters of horticulture—Lord Lambourne, the Rev. Mr. Wilks and Mr. Dykes all being present with powers to present R.H.S. honours to worthy exhibits. Kelvin Hall makes an ideal venue for a show of this sort, spaciousness and good roof lighting contributing comfort and convenience alike to exhibitor and spectator, and seldom has this country seen a more magnificent floral spectacle than that provided under such amenable conditions. Undoubtedly the most prominent feature was the informative and eye-satisfying display of the Corporation itself. For over roof of the central avenue the space was converted into a veritable botanical garden. Two extensive designs were constructed in the centre, the larger being devoted to Tree Ferns, Palms and exotic plants; the smaller built up as a rockery, from the middle of which a multitude of miniature water-spouts fed a tiny lake, the whole lit up in the evening with cleverly placed coloured lights. Banked up at either side of these groups were borders of economic and decorative plants, including many kinds of utility shrubs from tropical countries.

The remainder of the floor space of the central hall was devoted to competitive exhibits of greenhouse and stove plants, of which the finest example was shewn by Messrs. Cypher of Cheltenham, who gained first prize and the President's Cup, presented by Sir John Reid.

Ranged along the sides of this portion of the central hall were exhibits by the well known firms. Here Messrs. Sutton of Reading shewed the possibility of staging a multitude of vegetables, fruit and flowers in perfect taste as regards colour blending, the floral background comprising large vases of Gladioli and Lilies, while little groups of well chosen flowers relieved the solid array of excellently grown vegetables and fruit in the foreground.

On the opposite side, Messrs. Dobbie of Edinburgh made a flower show by themselves, a range of exhibits seldom, if ever, exceeded by a single firm at any show. A staging run of 175ft. had been used to the utmost advantage and included immense banks of Roses, Dahlias, Chrysanthemums, Phloxes, Antirrhinums, Begonias, Fuchsias and Pelargoniums, both Regal and Zonal. The firm's new Roses, Mrs. Frank J. Usher, deep yellow, flushed carmine; Lady Elphinstone, apricot; and Vanity Fair, salmon yellow, were well shewn, and another notable flower was Begonia narcissiflora, with quite a frilled trumpet, instead of the usual central row of petals. Pansies, too, were here in perfection, as they can only be grown in Scotland. Terminating this long run of staging was a group of the famous Dobbie Potatoes, three new varieties being shewn, Di Vernon, a first early, immune; Katie Glover, a new pink-eyed second early; and Crusader, a grand main crop, yielding many tubers of moderate size and of high cooking quality.

Perpetual-flowering Carnations made a brave show staged by Mr. Engleman, his newer sorts, Laddie, Tarzan and Topsy being in excellent form. The last named is a glorious deep crimson and an

excellent vase flower. Messrs. Allwood, too, had a large exhibit, including the ever-flowering, bright crimson-scarlet Carnation, Edward Allwood, Marion Wilson, maize with scarlet flake, and Wivelsfield Apricot, were also prominent, and the well known Allwoodii Pinks made a good display. In spite of the late season, Messrs. Blackmore and Langdon had a fine range of Delphiniums, secondary spikes doubtless, and the different tones of blue threw up the warm and glowing colours of a choice lot of double Begonias which were staged in the front of their exhibit.

Orchids were well represented by groups from Messrs. Charlesworth and Co. of Hayward's Heath,

GLADIOLUS PRIMULINUS GOLD DROP, SHAWN BY MESSRS. LOWE AND GIBSON.

Gladioli were an important feature of the Show.

Messrs. Sanders of St. Albans and Mr. D. McLeod of Chorlton, Manchester. Apart from the well grown exhibits of Gladioli shown by Messrs. Ryder of St. Albans and other firms who used them as specimen vase plants, one was pleased to see the glorious spikes of these flowers shewn in competition by Messrs. Mair of Prestwick and Mr. Airdrie of Dumfries. The Scottish climate suits the Gladiolus very well and we have seldom seen flowers in such magnificence of size and colour as these two exhibitors put up. Messrs. Lowe and Gibson of Crawley Down also had a collection of choice and rare Gladioli, in which they seem to specialise, their flowers including some of the ruffled type which has taken such a hold of the American flower-loving public. Particularly attractive in this exhibit were the vases of beautiful Gladioli produced from seed sown in February of this year.

Sweet Peas were, naturally, in great force as the season in Scotland has been suitable for strong growth and late flowering. We were pleased to see

a beautiful group staged by the time-honoured firm of Eckford of Weir, who, we hear, are again making great preparations for raising new varieties. The mass of colour supplied by these flowers came however from the competitive classes which were numerous and keenly contested.

It would be an endless task to notice even briefly all the individual exhibits in such an exhibition, but a few notes jotted at random may be worth chronicling. In Messrs. Forbes' stand, for instance, there were examples of the quaint inflorescence of *Poterium obtusum* among an admirable group of hardy plants, while on the Donard Nursery stage, among a representative lot of flowering shrubs and dwarf conifers, there were several hybrid forms of *Dierama pulcherrima* shewn under numbers, considerably deeper in colour than the ordinary form. Here, too, was *Eucryphia pinnatifolia*, seldom seen at flower shows and not quite hardy in these latitudes.

The Glasgow firm of Messrs. Austin and McAJan placed a very important group of conifers among which the steel blue of *Abies pungens glauca*, Koster's variety, rose prominently. In another exhibit they displayed vegetables and cut fruit, backed by tall vases of Gladioli, Perpetual Carnations, Lilies and Asters. Fruit trees in pots were capitally staged by Messrs. Learmont, Hunter and King of Dumfries, the Apples being in prime condition under good cultivation. It is interesting to record that Messrs. Samsons, Limited, of Kilmarnock, established their business so long ago as 1759 and that Burn's "Ode to Tam Samson" referred to the then principal of the firm. That prosperity still marks their efforts was shewn by the lovely collection of Roses, herbaceous plants, hardy fruits and fruit trees, and stove plants put up by them in a tasteful exhibit. We noted a very excellent strain of *Primula Littoniana* and the rarer *Primula glycosma* among a group of hardy plants from Messrs. Oliver and Hunter of Moniaive.

Another Scottish firm, Messrs. Laird and Dickson, had a representative selection of hybrid forms of hardy Ericas and a wide range of rockery plants.

Messrs. Storrie and Storrie, of tiny seedling repute, shewed fruit trees in pots—Apples, Pears, Figs and Grapes principally—and they were as well cultivated as any we have seen at the London shows. The flower department was represented by a good collection of greenhouse and hardy plants in pots.

Mr. J. Dobson, Glasgow, trading as "Leightons," whose business slogan is "Say it in Flowers," makes a speciality of sending cut flowers for any purpose to any address. He had a nice collection of hardy British Ferns, also a noteworthy plant in fine flower—*Begonia Martiana grandiflora*, very bright rose in colour.

A pretty feature of the exhibition was a competitive class for window boxes, some of which were most ornamental and ingeniously planted for colour effect.

Although Border Carnations are over in the South of England, some very fine specimens were seen in the classes for these flowers, Scotland this year being quite a month behind the usual period owing to lack of sun and warmth. The yellow ground Picotees were better than we have seen all the season in any part of the country, and the selfs and fancies quite up to the average standard of July in the South.

At the main entrance an excellent rockery was set up by Mr. David King of Edinburgh, an ambitious project backed by tall conifers and planted with appropriate shrubs and flowering plants.

The Show was an unqualified success and a strong feeling prevailed that the function should become an annual event.

CORRESPONDENCE

CARPETING THE ROCK GARDEN.

I AM sending you herewith two photographs of my rock garden. One shows a little valley clothed with *Festuca Crinum-Ursi*, that splendid Pyrenean Grass. Here it scarcely ever flowers. On a hot, dry site it maintained its fresh greenness right through the heat and drought of the summer of 1921. I have never seen *Lucarvillea grandiflora* so beautiful as when growing in this short natural turf. Such plants as *Anthericum* (*Paradiſea*) *Liliastrum*, *Ranunculus amplexicaulis* and *R. gramineus*, *Dianthus Carthusianorum*, the common *Gentianella* and *Adonis vernalis* are happy in this *Festuca*, which never requires

INTERESTING STEPS IN THE ROCK GARDEN.

A LITTLE VALLEY CARPETED WITH THE DWARF GRASS *FESTUCA CRINUM-URSI*.

cutting. Even *Gentiana verna* and *Primula nympha* have flowered beautifully this last spring in the same *Festuca* carpet.

The other picture shows *Cotula squalida*, *Thymus lanuginosa* and two dwarf Spruces, *Picea excelsa*

Maxwelli and *P. e. nidiformis*, in steps.—AKSEL OLSEN, *Kolding, Denmark*.

IS THE HOLLYHOCK DECLINING?

NOTES on the Hollyhock are interesting to me, as my apprenticeship days were passed with Messrs. Webb and Brand, Saffron Walden, Essex. As successors to the business of Mr. Chater this firm continued to make the Hollyhock a speciality and raised very large quantities of plants annually, there being a big demand for seed also. Propagation was effected by grafting, by cuttings, by division and from seed. At this time the rust (*Puccinia malvacearum*) was giving con-

siderable trouble, and numerous fungicides were tried to combat the disease, with varying degrees of success. The disease being seated within the tissues of the plant, remedies are difficult to apply. The rust is nursed by malvaceous weeds and often by the Musk Mallow (*Malva moschata*). Eventually a specific was prepared in the form of a dry powder, which was applied by means of specially constructed bellows, care being taken that the undersides of the leaves were thoroughly dusted. By efficient cultivation and the continued use of the powder throughout the season, the fungoid growth was to a great extent prevented. Beds containing many hundreds of plants with large healthy leaves from the ground upwards were a conspicuous feature of the nursery. Exhibitions of the flowering spikes and blooms gained many awards in London and the provinces. The Hollyhock is a gross feeder. Deep cultivation and rich soil are essential. In addition to liberal mulchings of manure, frequent applications of manure water should be applied during the early summer when growth is very active and a large amount of tissue is being produced by the plants. As an aid to the production of large, perfect flowers, and also to simplify the work of spraying, all offshoots that shew from the base should be removed. Strong stakes must be provided to which the plants must be carefully secured as they develop. If large blooms are desired, the buds may be thinned, also the top rains, or rains, (according to the strength of the plants) cut away. I believe that it has become the general rule with growers to treat the Hollyhock as a biennial.

Strong plants may be raised from seed sown very thinly in rich soil during May or early June. The seed should be covered lightly with sifted soil. If dry, a soaking of water should be given and the bed kept dusted over with soot until the seedlings are well established. The seedlings should be thinned to six in. apart. Some growers transplant straight to their flowering quarters in September. Others prefer to winter them in frames. In heavy loam or wet clay the latter plan may be advisable. In the southern counties and on light land, however, it is quite safe to winter Hollyhocks in the open, providing merely a light shelter of bracken or litter should severe weather occur. That the present proprietors of the Saffron Walden nursery—Messrs. J. Vert and Sons—continue to cultivate the Hollyhock with great success is shewn by the honours gained by their exhibits alike in London and the provinces.—C. RUSE.

THE SKUNK CABBAGE.

THERE seems to be a lot of disagreement about what is Skunk Cabbage. As a matter of fact, both *Lysichitum* and *Symplocarpus* are known as Skunk Cabbage, but in the West in British Columbia it is *Lysichitum camtschatense* that is called Skunk Cabbage and east of the Rockies it is *Symplocarpus foetidus*. In J. K. Henry's "Flora of Southern British Columbia" it reads "*L. camtschatense*, Schort. (Skunk Cabbage). Leaves often 1 metre long, acute, spathe yellow, 1-2 dm. long with a sheathing base." I may say that I have found leaves 4ft. long and 20ins. wide, but Henry makes no mention of the *Symplocarpus*, which apparently does not occur in British Columbia. On the other hand, in Schuyler Mathews' "Field Book of American Wild Flowers" it gives "Skunk Cabbage, *Symplocarpus foetidus*. Dark purple-red and green," and there is no mention of *L. camtschatense*, which apparently does not occur in the East. Both belong to the Arum family and both smell offensively, so naturally the inhabitants of their several localities call them Skunk Cabbage, as that animal has a continent-wide reputation for smell.—C. T. HILTON, *Port Alberni, B.C.*

PARIS AUTUMN SHOW.

THE National Horticultural Society of France will hold its International Autumn Exhibition of Chrysanthemums, Fruit, Vegetables, etc., in the Palmarium of the Jardin d'Acclimatation. In conjunction therewith the French Chrysanthemum Society will hold its Annual Conference. The Exhibition will open on October 27 and close on November 5.

Having received several enquiries from possible English exhibitors and also being in receipt of a very pressing invitation from the Chrysanthemum Section to induce English exhibitors to enter for competition, I shall be pleased to furnish any particulars that may be required.—C. HARMAN PAYNE, Foreign Secretary, National Chrysanthemum Society, 105, Wellmeadow Road, Catford, S.E.10.

THE ATLAS CEDAR.

VISITING Woodstock Park near Sittingbourne recently, attention was arrested by the beautiful cones freely borne by two aged Cedars, survivors of a group of three, growing at a distance of only a few paces from each other. Standing upright on the flat branches, these large, curiously marked green and red cones shew to great advantage. Though not rare, such fruiting of the Cedar is far from common and is of great natural interest. This ancient park, beautifully undulating and commanding a magnificent prospect over the historic country of the Lower Medway, contains many other arboricultural features. A Spanish Chestnut, whose

branches have reached to the ground, rooted and grown to a considerable size, covers an area of about 120 paces circumference. There are several other ancient Chestnuts, but the Walnuts are the characteristic of the park. Many are three centuries old and isolated, and have an immense and symmetrical reach of branches. A Copper Beech before the carriage entrance of the mansion about equals the width of the house. Woodstock Park is a survival of the old England of tradition and story which is fast passing away and without which England is the poorer.—HURSTCOT.

SOME POINTS ABOUT DAFFODILS.

I WAS simply amazed to see *Narcissus Ornament* (THE GARDEN, April 22, page 191) described as "a glorious Barrii." It was sent me from England when a comparative novelty about five years ago, if I remember rightly, as a substitute for *Heroine*. It has bloomed here under varying circumstances and soils, but always with the same result—a small and poor flower, lacking form and with a sort of nondescript orange cup. The much-vaunted *Homespun*—which we had many years ago and have tried from several different lots of bulbs in all sorts of soils and situations—has also proved a disappointment, as it has always flowered as a small thing of washy yellow, and of form which I need not hesitate to describe (if slangily) as rotten. Both of these varieties, if appearing in seedling beds, would be promptly discarded here. On the other hand, *Princess Mary* and many of her seedlings are uncertain doers here but, when they do well, are really magnificent. *Whitewell*, too, for some obscure reason rarely does itself justice, though a good flower.

I have had the same experience with *Bernardino* as Mr. H. G. Hawker (May 20, page 242). Last season almost all *Bernardino* and many *Ivorine* were deformed and many *Bernardino* went "blind." As to this "blindness," it seems to me that out here it is very largely (but not wholly), due to lack of sufficient moisture during the growing period prior to flowering time. In dry seasons many varieties suffer in this way, so now, when the weather is dry (especially in autumn), we always water the beds to be on the safe side. Varieties very prone to go "blind" are *Bedouin*, *Bernardino*, *Lulworth*, *Kittiwake*, *Lord Kitchener*, *Diana*, *Minnie Hume* (worst of all), *Queen of the North*, *Thistle*, *Sailor*, *Lavender*, most of the doubles and several *Poets* and *Barris*, but no *Trumpets* and very few *Incomps*. *Plenipo* has never flowered yet, though it grows strongly every year—can anyone give a reason for this? At present we miss *Maximus* very much, as it is "on strike" again, its shyness of flowering being its greatest failing.

As regards abnormal seasons (Mr. Pearson's letter on the same page), the vagaries of season, it must be admitted, are somewhat of a trial, though here we would never have a series of frosts such as recorded by Mr. Pearson, as frosts in this locality are extremely rare by mid-season, which normally may be reckoned roughly as about August 23 to September 7. I well remember the freak seasons of 1916 and 1919. In 1916 the season was normal till about August 20, that is, only the very early and the early flowers in bloom. I was called away from home for about a week and on my return to my surprise found that almost all were in full bloom except the later varieties! After that the season was soon normal again. In 1919 we had the shortest season I have ever known, September being unusually mild, the blooms after about the second of that month simply rushed into flower and about the twentieth the season was completely over. The present season is late by at least a fortnight, although the tazettas opened at their usual time, end of May and early June. AUSTRAL, *Geelong*, *Victoria*, *Australia*.

A BEAUTIFUL SHRUB.

THE shrub shown in the photograph is growing in the garden at Nuthall Temple, Notts, and is, I think you will agree, a very fine specimen of *Eucryphia pinnatifolia* (the Brush Bush), a native of Chili, which has pinnate leaves and large white flowers about 3 ins. in diameter. It is 17 ft. 6 ins. high.—R. H.

[The chaste, somewhat *Rose-of-Sharon*-like blossoms of this glorious tree will be familiar to most readers, but there can be few British specimens of the size of the one illustrated.—ED.]

ANEMONE-FLOWERED DAHLIAS.

FROM a passing allusion on page 438 it seems that some persons are under the impression that *Anemone*-flowered *Dahlias* are a new type. The one figured on that page, *M. C. Dupont*, may be in some points, but it is quite certain that the *Anemone*-flowered form of *Dahlia* was produced by growers at a very early stage in the European history of that flower. Want of time just now prevents my making anything like a systematic search among my old *Dahlia* records, but when I turn up "*Sweet's Florists' Guide*," Vol. I (1827-29), I find on plate 110 a very good example of the type then known. It is called the "painted lady *Anemone*-flowered *Georgina*." The text tells us "the present handsome variety belongs to a new tribe, known by the name of *Anemone*-flowered amongst cultivators, the flowers having their centre composed of narrow radiated florets, like the small petals in the centre of a double *Anemone*." It is more than probable that in the subsequent fever for the show and fancy varieties, the *Anemone*-flowered *Dahlias* fell into disfavour and were but little esteemed by our exhibitors.

They were, however, known in Germany, for *Jakob Ernst von Reider*, a most voluminous writer on floriculture in that country, tells us in one of his little manuals, "*Die Beschreibung und Kultur der Georginen*, etc.," Ulm 1834, that the *Dahlia* was then divided into four classes, of which the third is given thus:—

III Klasse: *Anemonenartige Georginen*.

It is not necessary, perhaps, to explain to the reader interested in the *Dahlia* that about the date mentioned florists in England, France and Germany had to a great extent adopted *Willdenow's* name of *Georgina* for *Dahlia*.

Anemone-flowered *Dahlias* may have remained in cultivation on the Continent ever since they were first obtained from seed, but to make sure of that conjecture necessitates time. At any rate, fifteen years ago, when *Rivoire* of Lyons published their little book "*Le Dahlia*," they included a section of what they called "*Dahlias Gloria*" (ou à fleurs d'*Anemone*), in which twenty-one varieties are included.

A MAGNIFICENT *EUCRYPHIA PINNATIFOLIA*.

Although my old friend *George Gordon* makes no reference to the *Anemone*-flowered *Dahlia* in his work on that flower in "*Jack's Present-day Gardening Series*" in 1913, it is worthy of note that *Wroe* in "*Dahlias and Their Cultivation*," five years before, does refer to them and says they were then a recent introduction from the Continent, dating to the year 1901.

They are certainly known in America, for they are mentioned in *Circular No. 43* of the *New York Agricultural Experiment Station* (1915), and in *Mrs. Stout's* new work, "*The Amateurs' Book of the Dahlia*," recently noticed in your columns.—*C. H. P.*

AN EXPERIMENT WORTH MAKING.

THAT pretty blue flowered shrub, *Clerodendron ugandensis* has recently become popular in this country. Curiously enough here it is looked upon as a climber and in the greenhouse at *Kew* it certainly has such a habit. In its wild state, however, it is a low shrub, not more than a few feet high.

It is a sun lover, growing only in grassland, or open bush country. In parts it is burnt off annually during the grass fires, which take place in the dry season. The woody stems of the plant, however, do not appear to suffer, for it grows up again in the rains, and it is particularly abundant in such situations.

I have seen this species growing at an elevation of 7,000 ft. in *Kenya Colony*, so it appears worth while trying as a summer bedding plant out of doors. At the high elevation the species was particularly floriferous. Judging by the rapidity of its growth after a grass fire, our English summer should be quite long enough for it to flower in if strong plants were put out in June.—*E. BROWN*

GARDENING OF THE WEEK

FOR SOUTHERN GARDENS.

The Kitchen Garden.

Maincrop Potatoes.—Make the best use of available time during dry weather to get all Potatoes lifted, as there is nothing to be gained by their being left longer in the ground. Where the work is unavoidably held up for some weeks, the haulm should be cleared away so that all light and air possible may reach the ground.

Tomatoes.—The present season has proved once again the futility of placing much reliance upon outdoor Tomatoes, for in the majority of cases, according to the reports, they are a poor lot. Cut off all the bunches as soon as they commence ripening and finish in a slightly warm building, such as a greenhouse, and thus allow the small fruits to have all the encouragement possible to swell up to a usable size for pickling and chutney purposes.

Brussels Sprouts.—These, in common with the majority of the Brassica family, have made an abundance of growth. It may prove advisable—indeed necessary—where the crop is in an exposed position to secure some of the taller-growing plants by staking. The bottom leaves should now be removed so that light and air can penetrate more freely.

Endive.—Plants raised during the latter part of June and early July will need treatment for blanching. The moss-leaved ones should have a flower-pot placed over them for the purpose, but the other varieties may be tied up in similar manner to Cos Lettuce. See that the late plants, which are now being got out to stand the winter, are given a light soil and a warm border.

The Flower Garden.

Pæonies.—From now until the latter part of October is the most favourable time for planting these beautiful spring-flowering plants. There are two groups, namely, the herbaceous and the "tree." The herbaceous are much more extensively grown, and may be used with good results in several ways. Unquestionably the most effective results are when they are planted by themselves in bold beds about the grounds in semi-shady spots or by the side of the pathways in the woodland garden. When preparing the site for them incorporate some well rotted manure and afterwards only disturb them when they need redividing, for the less disturbance the more flowers. The tree Pæonies do not appear to mind a great deal what the soil is, but as they flower quite early in the season a cold retentive soil cannot be expected to enable the plants to give such returns as a warm sandy soil would. Where it is necessary to have something in flower later than the Pæonies it may easily be provided by planting bulbs of Lilies, the large-flowering type of Gladioli or Hyacinthus caudicatus. A very pretty early spring effect may be obtained where there is a large bed or border devoted to the herbaceous Pæonies by planting yellow Narcissi among them. Flowering, as they frequently do, just when the Pæonies are unfolding their first leaves, the many delicate tints of foliage help to make the picture quite a pleasing one.

The Hardy Fruit Garden.

General Notes.—In addition to the gathering of early Apples, Peaches and Pears, care must be taken of the late Plums, which are often of great use for dessert purposes, but must not be gathered too soon. Particularly does this apply to Coe's Golden Drop. Mulberries where grown and required for bottling purposes should not be too ripe for the purpose or they may present a bruised and pulpy appearance in the bottles. The cold, showery and sunless weather has been all against Fig fruits finishing in a proper manner, so where the removal of an unnecessary growth or the tying aside of a few leaves will be of benefit to finishing fruits let it be done at once. The gathering of Nuts will soon call for attention, but this is essentially a crop which must not be collected until quite ripe and the Nuts ready to drop from their husks, or a goodly number will shrivel. The harvesting of all kinds of fruits offers a good opportunity to get doubtful names verified or corrected, as the case may be.

Fruit Under Glass.

Early Peaches and Nectarines growing in tubs and pots which will be called upon to supply the earliest fruits should now be taken in hand and receive the necessary repotting. Assuming the plants are now occupying receptacles as large as intended for them, a small portion of the old ball of soil should be gently liberated with a

pointed stick. The tree can then be replaced in a clean receptacle of similar size and the compost very evenly and regularly worked around it, to do which the aid of a somewhat thin and flatish potting stick will be required. The compost should be good fibrous loam to which a little bone-meal, wood-ash and old mortar rubble has been added, and it is important that the soil be made very firm. When all the trees are dealt with, stand them fairly close together on a bed of ashes, giving a couple of syringings a day for about a fortnight, unless the weather is showery. See that a thorough watering is given so that all the new soil is nicely settled round the roots.

H. TURNER

(Gardener to Sir Henry H. Houldsworth, Bart.),
Albury Park Gardens, Guildford.

FOR NORTHERN GARDENS.

The Kitchen Garden.

Potatoes.—Mid-season varieties should now be lifted at the first favourable opportunity and stored in a cool cellar or clamp. A sunny day should be chosen for the work and the tubers be left lying on the surface for a few hours to dry before finally storing. Tubers that are a suitable size for seed purposes should be laid aside and boxed. The seed boxes should be placed in an airy loit where the tubers will be free from frost.

Celery.—As growth advances, earthing up must be attended to. The stalks should be tied together with raffia to prevent the soil from working into the centre of the plant. Where the soil is lumpy it should be broken into a fine condition before placing round the plants.

Late Peas.—Owing to the dull and wet weather experienced in northern gardens this autumn, late Peas are slow to swell their pods and in many gardens considerable anxiety is felt regarding the success of the ordinary late sowings. Swelling may be assisted by pinching the tops, while a good watering of liquid manure may be given in cases where the ground is not over rich.

Turnip-rooted Beet.—All Turnip-rooted Beet from ordinary sowings should now be lifted and stored in an open shed, working sand freely among the roots so that they may keep in fresh condition through the winter months.

Spinach Beet.—Late sowings should now be thinned freely and the ground between the lines loosened with a cultivator or hoe.

Tomatoes.—A little more heat should be kept in the pipes to help the later trusses of fruit to attain good size and flavour. Care must be taken at this time to accord reasonable ventilation, since a close atmosphere tends to cause the fruits to drop before ripening.

Fruit Under Glass.

Vines.—In vineries where the Grapes are ripe, free ventilation must be given at all times when the weather is favourable in order to keep a buoyant atmosphere. Just sufficient heat should be maintained in the pipes to warm the air. Too hot a temperature not only encourages red spider, but also causes the berries to shrivel. Immediately the Grapes are cut, give the inside border a good soaking of diluted liquid manure. On vines carrying healthy foliage this feeding will materially assist bud development. An important point in Grape culture is to keep the foliage in a perfectly healthy state till it falls naturally.

Orchard-house Trees.—The general re-potting of all pot fruit trees cleared of their crops should now receive attention. Some may for this year only require top-dressing and this may also be done now. Trees re-potted at this season emit new roots and recover quickly before wintry conditions set in. Loam of good quality should be employed, adding a fair sprinkling of ½-in. bones and bone meal. Pick out as much of the old soil as possible from the roots, using a pointed stick for the purpose. Pot firmly by ramming and stand the trees outdoors for a month or two. For stone fruit the addition to the compost of some lime rubble from an old building will prove of benefit.

The Flower Garden.

Hardy Borders.—To maintain tidiness in the hardy borders extra attention should be given them at this time, cutting away all withered seed tops from plants that are past flowering; this will allow such late-flowering plants as Michaelmas Daisies, Phloxes and perennial Sunflowers more light and air to develop their blooms.

Rambler Roses.—Immediately these pass out of flower opportunity should be taken to cut out

as much of the old wood as possible, tying in the strongest shoots of the present year's growth.

Border Carnations.—Rooted layers should now be lifted and put into 4in. pots, half plunging the pots into ashes for the winter. A part of the frame ground should be chosen where a light may be placed over them during severe weather. In favourable districts many of the more hardily constituted sorts may be planted out direct into their flowering quarters.

JAMES McGRAN

(Gardener to Sir Henry H. Houldsworth, Bart.),
Coolham, Kilmarlock.

GREENHOUSE AND CONSERVATORY.

Sweet Peas.—Where it is desired to grow Sweet Peas in pots, they should be sown towards the end of the month. Although they transplant readily, it is best, where only small quantities are required, to sow them directly into large "sixties" or "48" sized pots, placing five seeds in a pot. The compost should consist of a good rich loam with the addition of a very little thoroughly decayed leaf-soil and enough coarse sand to keep the whole porous. It is advisable to file or chip some of the varieties that have a hard outer coating. After sowing stand the pots in a cold frame, covering the pots with pieces of glass to protect from mice, or the seeds may be coated with red lead. After germination they should be given full exposure to light and air, drawing off the frame lights on every favourable occasion, as it is not desirable that they should make much visible growth during the dull days. Although making little top growth, they will, if properly treated, make quantities of roots. Early in the new year they may be transferred directly into their flowering pots, which may be 10in. or 12in. in size. With so large a shift watering must be carefully done until the roots get a good hold of the new soil. As soon as they require it, they should be carefully staked and be kept regularly secured to their supports. They should be given perfectly cool treatment at all times with full exposure to light and air. Apart from their value for supplying cut flowers, well grown specimens are always much admired in the conservatory.

Oxalis floribunda (syn. rosea) and its white variety and *O. purpurata* (syn. *O. Bowiei*) are all beautiful greenhouse plants. Although once very popular, they are by no means so generally grown at the present day as they should be. They make pretty and useful pot plants for the cool greenhouse and very elegant basket plants. The dry tubers can be purchased at this time. Where stocks already exist they should be turned out of their pots and the largest tubers selected for potting up. They grow well in any good potting compost, and 6in. or 7in. pots are the most suitable size for them. After potting they may be stood in a cold frame and watered sparingly until they commence to grow. They may remain in the frame until they show signs of flowering, when they should be given a light position in a cool greenhouse. They flower during the early summer months. After flowering, water should be gradually withheld as the foliage dies down. They should then be kept dry in a cold frame until it is time to repot them.

Ixias and Babianas are both natives of South Africa. The corms should be potted towards the end of the month or early in October. The former can be had in a great variety of colours, many named varieties being offered for sale. They are very elegant plants, and are excellent for a supply of cut flowers. The corms are small, and six or eight may be put in a 5in. pot. They enjoy a light rich compost, and some well decayed mushroom-bed manure may with advantage be included in this. In common with all South African bulbous plants, they must have good drainage. After potting they should be stood in cold frames and given very little water until they have started into growth. In every respect they require the treatment from time to time suggested in this column for other South African bulbous plants.

Vallota purpurea is another beautiful bulbous plant, also South African, which one seldom sees in good condition in gardens, although it is commonly seen growing to perfection in cottage windows. Where fine well established specimens are flourishing it is a great mistake to disturb them, as this is by no means an easy plant to establish. Established specimens often get overcrowded with offsets, which should be removed and may be potted up if it is desired to increase the stock. About this time dry bulbs may be purchased. According to size, four or five may be put in a 7in. pot. They do best in a good

medium loam with very little leaf-soil added, but plenty of clean coarse sand to ensure perfect drainage. Very little water should be given until plenty of new roots are produced. It is probably at this stage that most cultivators fail, for if too much water is given the soil gets sour, in which condition it is impossible for new roots to develop. On the other hand, some growers

dry them off, which is a mistake, as the plant is really evergreen, although when it has completed its growth the plants may with advantage be kept on the dry side for a time. They are subject to attacks of mealy bug, which must be carefully guarded against. Quite cool treatment is essential at all times.

Royal Botanic Gardens, Kew. J. COURTES.

SOME SUPERLATIVE SWEET PEAS

ALTHOUGH I cannot claim to have had the long experience with Sweet Peas that the writer of the article on page 424 has, I have grown all the best of the modern varieties during the last ten years, so that I venture to give an opinion on the merits of the most important kinds.

It is true that one cannot name, say, a dozen varieties and term them "The Best Sweet Peas," for individual tastes regarding colour differ so much and different growers require their blooms for different purposes, but there are certain varieties that invariably succeed in most localities, and these eventually become the popular kinds.

Unfortunately there are certain varieties that are not sunproof, but as these embrace some of the loveliest of the shades, it is worth while to protect them from the strong sunshine if the somewhat unsightly appearance of shading material can be allowed. I have tried, this year, a neater plan of shading. My Sweet Peas are grown on wire netting secured to strong posts and all the varieties which are not sunproof are planted together. Above these, tanned cord netting (such as is used for protecting fruit) is stretched tightly and secured to the top of the wire netting and the posts that come between. Then strips of white calico are cut to such a width that there is a space of about six inches on either side to allow the rain to reach the roots of the plants and prevent them from becoming drawn. This is fastened to the cord netting and the whole is made secure from being blown about by strong winds by tying canes across, which rest just below the shading material. This is not unsightly, and it is the most effective way of shading that I have yet found out.

I will deal with these exquisite shades that need protection first. Tangerine Improved is the best orange and *Gloriosa* the best orange-scarlet. The latter is much superior to *President*, a variety that will soon be out of date. In a summer like the present, when the sunlight has not been so strong as it was last year, *Gloriosa* is practically sunproof, but it will lose a little of that rich orange fire in the standard when the sun is very hot. *Royal Flame*, a novelty for 1923, is an even more vivid colour, having the flame tint in the wings as well as the standard. These three varieties do best if a little leaf mould is added to the trench. *Royal Salute* and *Royal Scot*, mentioned as being "burners" in the article on page 424, are both perfectly sunproof, in fact the more sun they get the more brilliant is their colour. It is only in cold unsettled weather that the flowers lose their colour (or more correctly do not develop it) near the edge of the petals, and this may give rise to the mistaken idea that they "burn." In the salmon shades nothing is quite equal to *Salmon Queen*. It is most vigorous for a variety in this colour and produces blooms on very long stems, many of which are duplex. I have a fine patch of it this year, its first season out, and in 1920 and 1921 (when I was privileged to grow it for trial before its introduction) I found it equally good. *Mignonne*, which makes its appearance this autumn, is another lovely bit of colour and, when shaded comes the cleanest and softest of shades of pale cerise, resembling the pure tone of the *Cottage Tulip* *Cassandra*, the *Rose Cherry Page* and the new *Dahlia* *Norah Bell*,

but possibly a little more delicate than any of these colours. I have been pleased with *Mignonne* both in the heat of last year and in the cooler conditions of the present season.

The best scarlet that needs shading is *Burpee's Scarlet Duplex*. It is a more vigorous grower than *Hawmark Scarlet*, and gives more double standards. It has fine stems and altogether is a variety well worth growing.

One cannot leave the non-sunproof varieties without mentioning the orange-pinks. In this class *George Shawyer* and *Eva* are the two best. They are not identical, the latter having a very decided orange sheen in the standard, while in the former, the pink seems to be more flushed with salmon. Both are vigorous growers, and have long stems.

It must not be supposed that rich colours can only be found in the varieties that will not stand the sun. There is a sunproof scarlet in *Scarlet Glow*, a little different in tone from *Burpee's Scarlet*. *Doris* is most a beautiful cherry-pink, and *Glory* and *Hawmark Cerise* are both of similar colouring. All are sunproof. Then there is *Royal Scot*, scarlet-cerise, and, more vivid still, the new variety *Wonderful*, which glitters like rubies in the sunlight.

As a rich pink, *Hawmark Pink* provides a fine bit of colour, but it has not quite come up to expectations. I grew five stocks of it this year, the best that could be obtained, and although the colour is glorious, the habit of the plant is not vigorous and the stems soon begin to shorten. Even the best stocks give a few paler tinted blooms. *Hawmark Salmon Pink* is perhaps a little more stable in colouring, and generally a little richer, but I should like to grow this another season before coming to a definite decision.

Picture is undoubtedly the finest of the deep cream pinks, a giant flower of superb colouring. In the pale cream pinks there are several superlative sorts. *Mrs. Arnold Hitchcock* (Messrs. E. W. King and Co., have a very fine stock of this), *Cecily*, *Bessie* and *Fair Lady* are all extra good. This colour is exquisite for decorative purposes. *Mrs. Hardcastle Sykes* must now take second place to *Valentine*, one of the finest varieties in commerce and a beautiful shade of blush pink.

John Ingman must be grown from a very select stock, and there are but few of these about now, to equal *Renown* and *Mascott's Ingman*, two very fine new varieties. *Mrs. Tom Jones* is not as good as it was two or three years ago and I have seen one or two very fine blue seedlings that may possibly supersede it. *Colne Valley* is the best of the pale lavender-blues, *Elsie Dene*, the best pure light blue (under glass it inclines to lavender), while there is very little to choose between *Commander Godsall* and *Jack Cornwall V.C.*, in the dark blues. In lavenders, *R. F. Felton* still makes good and it has been a wonderful variety, but *Austin Frederick Improved* seems destined to lead the way among the rosy lavenders. It is tremendously strong, has huge stems and gives big blooms mostly in fours. The new variety *Powercourt*, which Messrs. Alexander Dickson's hope to introduce this autumn, will probably lead the way in pure lavenders. Mr. G. T. Dickson sent me a box of lovely blooms the

other day, almost the last word in Sweet Pea perfection, every spray a four, all the stems long and stout and the flowers proportionately large and well frilled.

I am still convinced that *Constance Hinton* is the largest white. I grew three of the best stocks of this, but they required the sunshine of last year to make them equal in purity to *Edna May Improved*. A lovely frilled white is *Innocence*, which I recommend for those who like a pure white that is really white in all weathers. *Matchless* is the best cream till another from the same raiser beats it, but that will not be yet. In the dark shades *Warrior*, *The Sultan* and *Splendour* will supply three different colour tones for those who like these shades. The picotee-edged varieties are very beautiful, *Anne Ireland*, white ground, and *Improved Jean Ireland*, cream ground, are the only ones required. The latter is a novelty for the coming season, which Mr. Woodcock hopes to distribute. I have grown it this year and it is a decided improvement on the old variety, having exceptional vigour and giving a larger proportion of four bloomed sprays. With the exception of these daintily edged varieties, self shades are the most popular, and there are now so many fine varieties that it becomes increasingly difficult to decide which to omit in making selections.

NORMAN LAMBERT.

THE ROYA VALLEY IN THE MARITIME ALPS.

THE long valley ascending from *Ventimiglia* and leading to *Tenda* is one of the richest in the Maritime Alps. Perhaps this is due to the fact that it is better known than others, as the Rev. Bicknell has written largely about it as well as Dr. Mader. It is one of the most picturesque and curious of them all. At its foot along the *Roya* one may see thousands of *Nerium Oleander* flowering from May to October, and the common *Myrtle* and *Rosemary* springing up from every rock. Near *Tenda* one finds the alpine flora (*Saxifraga lingulata*, *S. diapensioides*, *Lilium pomponium* and *L. Martagon*, *Alyssum halimifolium*, *Globularia nana*, *Iberis*, *Primula marginata* and *latifolia*, etc.) The valley is 50 kilometres long and the road passes through the most remarkable gorges imaginable.

I am just returning thence, and am still under the charm of its rich and beautiful vegetation. Let me tell your readers about it. At *Tenda* between the hardest rocks one finds the very rare *Moehringia papulosa*, whose silver leaves are the most curious of all that grow. Then near the old town may be found the very fine *Linum viscosum* with rose pink flowers and *Lilium pomponium*, the most brilliant of all the *Martagon* group. This *Lily* is the glory of the South with its vermilion crowns, which shine in the landscape as stars in the dark. It grows—very curiously—between rocks and stones, as no other *Lily* does, and goes very deep in the ground. The underground stalk is often covered with little bulbules which reproduce the plant as well as do the seeds, but more quickly, of course.

Sempervivum calcareum and *Saxifraga cochlearis* var. *minor* (*S. Probyni*) adorn the slopes, along with masses of *Campanula macrorrhiza* in sunny places. And then, if one turns into the small valleys, there is to be found the rare and curious *Eryngium Spinalba*, which is to the south-western Alps what *E. giganteum* is to the Caucasus, *E. alpinum* to the central Alps and *E. Bourgati* to the Pyrenees. *Micromeria piperella* with its pink flowers adorns every rock, and the dwarf *Globularia* extends its masses of grey foliage on the driest

places together with that of *Saxifraga cochlearis*. Above St. Dalmazzo the rocks are at the highest altitudes covered with big tufts of *Primula Allionii*, which is not so rare as is often thought, for the whole of the cliffs of red rock are covered with it. The thing, however, is to go high enough to reach it. The plant is there in such quantities and in such inaccessible places, growing always on the face of steep cliffs which no man can traverse, that there is no need to conceal its station. The plant's nature protects it against vandals. There are, besides, masses of *Moehringia sedoides* (= *dasyphylla*) and of *Potentilla Saxifraga* growing on these perpendicular walls, adorning them jewel-like. A very curious *Daphne* (*Thymelæa dioica*) forms large tufts of grey foliage together with the orange discs of *Plagius Allionii*. What a display all these flowers together provide and how sweet is the scent of all the various herbs—*Satureia*, *Hyssop*, *Lavender*, *Thyme*, *Rue* and *Nepeta*.

The Lady Maidenhair (*Adiantum Capillus Veneris*) and the curious climbing shrub called *Ballota spinosa* hang in shady and damp places, and the rare and curious *Pinguicula longifolia* can, or rather could, be found in masses on damp rocks near Fontan. I say "could be," as now the rocks where once it grew are all obliterated by the engineers who constructed the railway. It is to be hoped that the plant has higher stations on which it has carried on; near the road every bit is destroyed.

Fontan is the first French village when descending from Tenda. Quite a little place, it is the best centre anywhere about for botanising expeditions. The walls and red rocks are the best home for *Primula Allionii*, and the slopes are rich in *Lilium pomponium*. Above the high rocks Bicknell found the rarest of all the Campanulaceæ, *Phyteuma Balbisii*, and I myself found there *Woodсия hyperborea* and *Aquilegia Reuteni*. *Hypericum Coris*, *Micromeria piperella*, *Lilium viscosum* and *gallianum*, and *Saxifraga cochlearis* are everywhere, and if one follows the beautiful Val Cairois to the Col de Raus, one comes to fields of *Lilium pomponium* growing as thick as the grasses in our meadows.

The little town of Saorge, hidden among the Olive trees, is quite a picturesque one. There grow *Saxifraga cochlearis*, *Ruta bracteata*, *Lavandula officinalis* and *Stoekas* in masses. And on the rocks which command the town *Primula Allionii* can be found. *Salvia Sclarea* and a great many odoriferous herbs are growing along the roadside, and under the Olive trees in the earliest spring there are myriads of *Aneuroles* and of *Gladioli*. Here the colours are brighter than I remember noticing in any cultivated garden.

There is, high above the village of Fontan (three hours' walk), a little peak called La Cèva. It is reputed to be the richest in vegetation of the whole chain, and has been compared to the famous Lantaret, above Grenoble. I went there last month and found the most brilliant flora I could imagine (*Lilium pomponium* and croceum, St. Bruno Lily, all kinds of Orchids, four different *Gentians*, *Phyteumas*, *Campanulas*, etc.). It may be considered as an epitome of the flora of the Alpine meadows, but contains nothing of exceptional rarity. H. CORREYON.

The National Rose Society. We understand that during the past two months the number of new members joining the National Rose Society is 200 per cent. greater than for the corresponding period of last year. Compared with pre-war year, 1913, the increase is even more remarkable, being more than 400 per cent. A record number of fifty-four new members joined at the last meeting. The present membership is close upon 9,000.

OBITUARY

MRS. R. V. BERKELEY.

It will be with a sense of almost personal loss that many readers will hear of the death of Mrs. Berkeley of Spetchley, who, like her sister, Miss Ellen Willmott, has done so much for horticulture. Not so much by what she had actually achieved in plant breeding, though her successes in this field were very considerable, but by the enthusiasm which she brought to bear on all matters connected with gardening, did Mrs. Berkeley make her influence felt. Great as was her love for beautiful flowers and the adequate arrangement of the growing plants, her influence and example in food production and distribution was equally remarkable when, five or six years ago, the danger of a serious food shortage was only too real. None who saw and admired her beautiful strain of coloured *Primroses* at Vincent Square only a few months ago had any inkling that that was the last time they would be shewn by their raiser.

JOIN MORGAN.

With the death of Mr. John Morgan, partner in the well known seed and nursery firm of Thompson and Morgan, Ipswich, which occurred on August 12 after a short illness, there passed away yet another of the select few who have a really comprehensive knowledge of hardy plants and their seeds.

Mr. Morgan, who had devoted his life to horticulture, was of a retiring nature and did not appear much in public, but he was an enthusiastic worker in the Ipswich and District Gardeners' Association, frequently presiding in a vice-presidential capacity at their meetings, while for the current year he was president. The business will, we understand, continue to be carried on under the old and well known name.

ANSWERS TO CORRESPONDENTS

QUESTIONS AND ANSWERS.—All communications should be clearly and concisely written on one side of the paper only, and addressed to the Editor of THE GARDEN, 20, Tavistock Street, Covent Garden, London, W.C.2. When more than one query is sent, each should be on a separate piece of paper. Plants for naming should be clearly numbered and securely packed in damp grass or moss, not cotton-wool, and flowering shoots, where possible, should be sent. It is useless to send small scraps that are not characteristic of the plant.

FLOWER GARDEN.

GLADIOLI FAILING (O. C. S., Warmminster).—The *Gladioli* appear to be attacked by the leaf-spot fungus *Heterosporium gracile*. The corms seem healthy and may be planted again next season, spraying the foliage with Burgundy mixture from June onwards to protect it against future attack. The diseased foliage should be burnt.

CHRYSANTHEMUMS, ETC., WITHERING (E. H., Surrey).—Something has been amiss with the water supply. Has the root been damaged in any way?

CHINA ASTERS DYING OFF (T. H. S., Andover).—Without seeing a specimen it is most probable that the Asters have succumbed to *Phytophthora* to which this plant is very subject. All affected plants should be removed and destroyed and the soil be well limed in autumn. The soil of the beds in question will be affected and our correspondent will be well advised to reconsider his decision to grow Asters in these beds next year. As plants in other parts of the garden are not affected there would appear to be no infection in the compost in which the young plants were raised.

ERYNGLIUM PANDANIFOLIUM (W. E. C., North Notts.).—This plant is moderately hardy in the south and should succeed in our correspondent's locality if it can have shelter from the north and east and, preferably, the partial shade of a tall tree. The light soil is quite suitable.

BLUE HYDRANGEAS (J. W. M., South Devon).—The applications should be commenced in the spring soon after growth has commenced. In addition to the substances named, it has sometimes been found that top-dressing the *Hydrangeas* with lawn mowings has had the desired effect.

AUTUMN CROCUSES IN THE GRASS (Beginner, Berks.).—The true autumn *Crocuses* are not at all likely to thrive if planted in the grass; these are decidedly bulbs for the border. But the *Colchicums*, which are sometimes termed "Autumn *Crocuses*," are eminently suitable and very beautiful when grown in grass. The best purple and purplish varieties are *C. autumnale*,

C. Bornmülleri, *lilac*, with white centre; *C. byzantinum*, pale mauve feathered with white; *C. giganteum*, dark lilac; and *C. speciosum*, rosy purple. The corms should be planted about 3 ins. deep in July or early August. It would be well to cease cutting the grass at the end of July as, occasionally, they flower early. The leaves appear in the spring-time, so the grass should not be cut until the foliage of the *Colchicums* has died down. Winter *Aconites* and spring *Crocuses* may well be planted in association with the *Colchicums*.

FRUIT GARDEN.

APPLE DISEASED (C. L., Petworth).—The Apple is attacked by the apple scab fungus, *Fusicladium dendriticum*. This fungus also attacks leaves and shoots and passes from one to the other by means of its spores. It is therefore important to destroy all diseased fruits and to prune out all shoots showing swellings between the leaf buds or cracks in the bark, in order to lessen the risk of disease next year. Just before the buds burst and again after the petals fall, spray the trees with Bordeaux mixture.

THE RIPENING OF APPLES (C. W. C., near Hertford).—Juncating is in season at the end of July; Duchess of Oldenburg and Grenadier during August and September; Worcester Pearmain during September and October; Warner's King, December to February; Rosemary Russet, January and February; Sturmer Pippin, March to May. Early Apples are best gathered as wanted from the tree. They rapidly lose flavour and crispness when gathered. Late Apples should be left as long as possible until the approach of rough weather or severe frost makes picking necessary. Sturmer Pippin may often be left on the tree until mid-November.

FIG TREE UNSATISFACTORY (G. G., Hassocks).—The tree has undoubtedly had a check to growth, probably owing to the exceptionally dry weather of last year. At the end of August, or not later than the middle of September the tips of the growing shoots should be pinched off. Embryo fruits will swell, but all half an inch long or more must be removed, as, if retained, they would partly swell towards maturity and then fall off; the smaller fruits are the ones to retain at the end of the season—October. If this work is done the tree will, no doubt, be quite normal again next year.

KITCHEN GARDEN.

CURLING BRUSSELS SPROUTS ("Brussels Sprouts," Surrey).—The leaves sent appear to have been attacked by aphids. Soap-suds sprayed on the plants will be the safest treatment to adopt. White fly seldom does any real harm outdoors, certainly not on Cabbages or their kindred.

MISCELLANEOUS.

STRAWBERRIES UNSATISFACTORY (R. J. W., Broughtly Ferry).—Your plant is *Phormium Cookianum* (New Zealand Flax). The Strawberries sent appear to be old plants, and this would account for their failure. No Strawberry bed should be left beyond three years. The soil appears to need a dressing of lime.

PLANTS ATTACKED BY INSECTS (Austral, Geelong, Australia).—The insects referred to are doubtless spring tails (*Collembola*), but if so they have only six legs, not many. They rarely do much harm unless they are very numerous and food is scarce. They appear to feed mainly on decaying vegetable matter, but may sometimes attack living plants. Where it can be applied water at 110° Fahr. will kill them, but if this cannot be used, a very weak solution of potassium cyanide (one-tenth of 1 per cent.) may be tried, or forking some naphthalene into the ground about the plants that need protection.

ACETYLENE GAS REFUSE (E. E. B., Frimley).—The refuse from an acetylene gas plant may be used on the kitchen garden as a substitute for lime, but it is not nearly so valuable bulk for bulk, so should be used in greater quantity.

NAMES OF PLANTS.—E. H., Wimborne—*Marrandia crubescens*.—M. E. P., Wellingborough.—1, Probably *Berberis vulgaris*; 2, *Selaginella Willdenovii*; 3, *S. Kraussiana*; 4, *S. Emiliana*.—J. W. R. B., Warmminster.—*Campanula Ljansomana*.

NAME OF FRUIT.—H. H. C., Caversham.—Pershore Plum.

Useful Garden Accessories.—We are informed that in deference to a distinct public demand the House and Garden Sundries Company are making their "Everyman's" netting brackets for wall fruits double sided to meet the case of walls with fruit trees on both sides. This is a particularly neat and satisfactory arrangement, forming when fixed practically a cantilever. The netting is readily fixed and taken down and the brackets themselves are quite neat and unobtrusive. At the present season for protecting ripening fruit, in early spring for safeguarding the buds from birds and still later for warding off spring frosts, these simple wall brackets should prove an unmixt blessing. The House and Garden Sundries Company also supply a particularly useful pin for securing the netting to the ground with a handle which, projecting just above ground level, makes it easy to find the pin when it is desired to remove it. Those who have tried their well known excellent layering pins, will appreciate the construction, for these netting pins are exactly similar, but one size larger.

A VEGETABLE GROWER'S HANDBOOK

BY

Mrs. FANNY BENNETT, F.R.H.S.

*Author of "The Best Way" Flower Garden Book," etc.
Gardening Expert to Amalgamated Press.*

AND

ELEANOUR SINCLAIR ROHDE,

Author of "A Garden of Herbs."

This Manual has been practically written by two practical gardeners.

Mrs. FANNY BENNETT needs no introduction to those who delight in gardens, as her admirable articles on horticulture in the *Daily Mail* and other journals are appreciated by a very wide public.

This Handbook is written for those who wish to ensure success in the growing of vegetables, and should be specially useful to beginners and the many thousands who are planning a kitchen garden on uncultivated ground for the first time.

The writers have given extra space to the potato, onion, pea and bean crops, because these are of the highest food value; each vegetable is the subject of a separate section.

The Calendar, showing the gardener's work for each month in the year, is useful for reference. The whole book is full of valuable hints gathered from many sources and proved by personal experience.

WRITTEN IN SIMPLE NON-TECHNICAL LANGUAGE.

BARR'S Beautiful New Seedling NERINES

The most beautiful and easiest grown of Autumn-flowering Bulbs for the Greenhouse.

For autumn decoration in the greenhouse few plants can compare with Nerines for their brilliant and attractive colours. The flowers, which are produced in umbels of 6 to 24 blooms, are borne on stout stems varying in height from 1 to 2 feet. In colour they range from *dark red, vivid crimson, cerise and scarlet* to *salmon, coral-rose, pink, blush and white*, many having a glistening lustre which in sunlight gives them the appearance of being dusted with gold or silver. They remain decorative for many weeks, and their beauty may be enjoyed in a sitting-room as well as the greenhouse, if the pots are kept in a sunny window.

12 in 12 beautiful named varieties .. 42/-, 50/-, 63/- and 84/-
6 in 6 " " " " .. 18/-, 24/-, 30/- and 42/-

ALPINES

To Flower in Winter and Early Spring

Use your Conservatory or Greenhouse as an Alpine House; no heat required. The following suitable plants—

- Adonis amurensis fl. plena, yellow
- Androsace Chumbyi, pink
- Cethionema Warley, rose pink
- Gentiana acaulis, deep blue
- Omphalodes cappadocica, rich blue
- Primula frondosa, lilac
- " Wardi, mauve
- Ramondia pyrenaica, lilac blue
- Saxifraga apiculata, pale yellow
- " Boydi alba, white
- " valdensis, white
- Sedum obtusatum, yellow

Sent Carriage Paid for 10/6. Smaller orders 1 - extra carr.

WISTARIAS AND THEIR TRAINING

EVEN those who have least love for Japanese gardens and Japanese gardening must admire the Wistaria. Like the Japanese Cherries it is "everybody's tree," and yet how many houses does one see smothered in various, more or less effective, climbing plants, but destitute of Wistaria? Why is this? For a house with any pretensions to architectural interest the Wistarias are surely the best of all climbing plants. (Climbing plants they are, though they cannot climb on a flat surface, needing something comparatively thin round which to twist the young wood.) The growth of both the commonly-grown species—the so-called Japanese, *multijuga*, and the Chinese, *chinensis*—is vigorous without being overpowering, so that they may be readily trained to adorn rather than to smother the front of the building against which they are planted.

The "Japanese" Wistaria, as we know it, has doubtless been considerably improved by the Japanese florists, but it is really a native of North China and probably not indigenous to Japan. It is magnificent for training over tall pergolas or on an elevated trellis. For walls it is really less suitable than *W. chinensis*, though by training main laterals horizontally and a sufficient distance apart, it may be shewn to advantage there also.

The association of various habited "furnishing" plants to architecture receives much less attention than it should. A bald uninteresting expanse of wall is caused by want of appropriate detail. If a cornice would have filled the bill in the original design, the bad effect can be at least greatly mitigated by training a Wistaria horizontally to replace the missing element. Similarly, living pilasters of *Cratogeomys*, for example, will provide upright features where desirable.

If the wood of the past year is reduced each winter to three or four eyes, the Wistaria will make a satisfactory self-supporting bush. Indeed, plants which have been stunted in pots in the nursery often retain the bushy habit. If they are

wanted to climb, care should be taken to purchase healthy young trees with an abundance of young wood. The pruning of a climbing Wistaria is (or should be), similar to that of a trained Pear tree. Laterals are taken off where required and allowed to extend reasonably each year until their allotted space is filled. The sub-laterals are summer pruned to ten or a dozen leaves—if this is not done there will be yards of thin growth tangled all together—and in winter spurred back to the flowering wood. With plants trained on

wires to give the "floral bell tent" effect so well known to visitors to Kew Gardens, the training may be more informal, but the same principles will apply.

The common form of the Chinese Wistaria has flowers of a delightful mauve tone, so distinct as to be a commonly used colour shade. The "Japanese" species is, in commerce, a much more variable plant, but if one can but obtain them, its best forms are darker and even more desirable as regards colouring than the Chinese. The length of the racemes in this species is extraordinary. The rosy form—*rosea*, is well known, but less beautiful than the mauve purple ones and there is a pure variety which is rather shorter in the raceme, though still long, and later to flower. The white form of the Chinese species is, strangely enough, earlier to flower than the typical plant. The general experience is that it is less free to flower than the typical mauve.

Like the Grape Vine the Wistaria develops quite a trunk and butt with age. A diameter of more than 18 ins. is not uncommon for the trunk of an old specimen. The Wistaria, fortunately, is comparatively long lived. Its introduction to English gardens dates back just over a century (1816), and some specimens now in existence must be close upon a century old. The oldest specimens, however, almost invariably shew signs of decrepitude with hollow trunk and diminishing foliage, so that the effective age of the plant may be placed at from eighty to hundred years.

In some seasons there is quite a good second crop of blossoms on *W. chinensis* in August. This has been very noticeable this summer when some plants were almost as laden in high summer as they had been previously at the end of May. This has also been a remarkable year for the amount of seed produced. Probably the hot summer of 1921 and the consequent ripening of the wood made for fertility. The velvety and singularly shaped seed pods are distinctly ornamental when produced in quantity.

There seems no reason why, in the south of England, the Wistaria should not be planted to overrun

WISTARIA MULTIJUGA¹ ALBA ON A HOUSE WALL.

trees just as one plants various *Clematis* species or *Rosa moschata* for the purpose. The long-racelled *W. multijuga* would seem best suited for the task as being more effective.

Bush *Wisterias* are, as a rule, planted to associate with water which, of course, redoubles their charm by reflecting the glorious trails of blossom. One feels that had these beautiful woody climbers been known in Tudor days, many of the pleached avenues of Lime and such like would have been

carried out in *Wisteria*. There really seems no reason, therefore, why those with old gardens (or with gardens to an old house), should not plant *Wisteria* to be trained in this manner. They would ultimately become almost, if not quite, strong enough to stand alone. It is not quite evident why, when reconstructing an old garden, we should be bound by the limitations which handicapped our forefathers. Surely it is better to build upon the past with whatever

of old or recent introduction will best serve the end in view! The *Wisteria* is assuredly an old-fashioned flower. Even though it has been cultivated for a mere century in Britain, it has been grown no doubt by the gardeners of Japan since long before Tudor times and it has that peculiar sophistication characteristic of plants long in cultivation.

As previously stated, both the *Wisterias* commonly cultivated in this country are of Chinese origin. Though sufficiently distinct, they are obviously closely related. There are, however, other species in existence of which two at least are Japanese. Of these the only one of which much is known, *W. japonica*, was introduced for Messrs. James Veitch as long ago as 1878. Compared with *chinensis* or *multijuga*, this species is a pigmy with numerous small white flowers in racemes 6 ins. to 12 ins. It is said to provide a wonderful spectacle when smothering a large bush or small tree, but is seldom seen in cultivation in this country. It is probably not over hardy unless in favoured situations, otherwise it would be particularly valuable, as it flowers in July and August.

The American species, *W. frutescens*, bears its flowers in short terminal racemes, often held erect. The flowers are pale lilac in colour, but it never gives a very striking display because the racemes do not display their beauty simultaneously. Commencing to blossom in June, it continues more or less in flower until the end of summer. A form of this or, possibly, a distinct species, variously called *W. frutescens magnifica* and *W. macrostachya*, bears larger racemes and is in every way a better plant. It is not readily procured in nurseries or would be well worth planting in southern gardens. It is an admirable tree climber.

The propagation of *Wisterias* is relatively easy. They may readily be layered or cuttings of the current season's wood, if removed with a heel as soon as moderately ripe (usually in August), will root satisfactorily.

As purchased, the plants are almost invariably grafted. Where grafting is carried out on to roots of the same species, it is comparatively innocuous, but plants on their own roots are safer. Grafting is easily carried out in spring under glass with a little bottom heat. It is truly astonishing, however, how grafting persists as a means of propagation for many plants which increase readily, not only from layers, but from cuttings.

In favourable seasons, seeds ripen freely and are easy to germinate. The seedlings do not, however, as a rule, produce very good forms. Seedlings of *W. multijuga*, in particular, are apt to be exceedingly "washy" in colouring and comparatively short of trail. If a good type be secured from seed, it has naturally abounding vigour. Seedlings serve the nurseryman for stocks on which to work better types.

WISTERIA MULTIJUGA ALBA AND *W. CHINENSIS* (TYPE).

A WISTERIA BOWER AT KEW.

NOTES FROM A SEPTEMBER GARDEN

IN a garden where the drainage is sharp, the soil porous and the aspect hot, the experience of an average summer does not lead one to expect very much in the way of colour in August and September. But the fierce heat of the earlier months, followed by sunless, rainy weather, has had the effect of giving us a garden that is now a gay medley of spring and autumn.

Most noteworthy, perhaps, is the rock garden, usually so bare just now, where such good old Aubrietias as Mrs. Lloyd Edwards, Dr. Mules and Perry's Seedling, are all bearing a fine crop of blossom on growth that would, under more ordinary conditions, not flower until next spring. That wonderful ally of theirs, *Arabis Sundermannii* is equally well covered with its delightful rose-pink blossoms. Indeed, it has not been out of flower since April and reached the height of its display in the drenching days of early August.

Among the smaller *Hypericums*, *H. polyphyllum*, which is almost a miniature olympicum, has surpassed itself as an autumn bloomer, a large plant being to-day (September 10) a silvery mass blazing with yellow. As chance would have it there is near this a mound of *Raoulia australis*, which loves a wet late summer as much as it detests a muggy winter. Its countless little leaves are so closely set and so silvery that it might be mistaken for a lichened rock, while over its frosty hoariness there is creeping, like a fungus, an eruption of tiny golden flowers. Yet another yellow planting, *Oenothera pumila*, is here and doing its best, a midget Evening Primrose no more than about 4ins. high.

Though autumn is the season of most of the Evening Primroses, such well known and admirable species as the yellow *macrocarpa*, *taraxacifolia* and *marginata* in white and *Arendsii* in blush have this year responded to the weather conditions with a more liberal succession of flowers and these of larger size than we have seen for years. This also applies to those pernicketty creatures, the rock garden *Erodiums*, for although some of them looked like saying goodbye to the grey skies six weeks ago, they have cheered up amazingly and are now growing well. One of the daintiest of these (also one of the most fretful), is *E. chrysanthum* which raises above its silvery leaves little fragile sprays of flowers in the most delicate citron yellow. Of *E.E.* *cheilanthifolium*, *trichomanefolium* and one or two more of a type whose foliage is more or less like the fronds of Parsley Fern in silver, and whose flowers are dotted or veined, plain or blotched "pink butterflies" poised on airy stems there is one which seems to possess the

charm of pure loveliness to a degree scarcely attained by others and that is *E. supracanum*. One's September garden need seldom be without the delightful china-white blossoms of *E. Reichardi*, standing about an inch above its deep green,

THE FREE-FLOWERING CLEMATIS COMTESSE DE BOUCHAUD.

prostrate foliage, but this year they have been more numerous than usual. *E. corsicum*, in rather a fierce pink, has also done tolerably well for what is ever a hypochondriac with us. As for the big and splendidly healthy *E. Manescavi*, let those who will find fault with its magenta blossoms. A plant that will, under almost any circumstances, produce a mass of rich green, ferny foliage and an unbroken succession of gorgeous *pelargonium* in bold heads from spring to Christmas and yet never prove aggressive or troublesome, is a possession to be thankful for.

Fuchsia procumbens (?) has been especially happy this summer. It seems to enjoy plenty of moisture, for the more it rained in August the further it crept and the more numerous its weird little flowers to-day. The latter look like antique candle-snuffers in a glistening, waxen, golden-yellow, with triangular, reflexed adornments in chocolate and a shrill green. These will be followed by dull red fruits as big as hazel nuts. Another curiosity which came here labelled *Lobelia Cavanillesii*, and of which I know nothing, has expressed its satisfaction with the weather by producing tubular flowers in a startling scarlet with a yellow throat which yawns into the semblance of the beak of some strange bird. *Cyananthus lobatus* has also done well and is still giving us its rich blue

bells in brown furry cups. With red stems and glossy green leaves, *Polygonum sinu-capitatum* is spreading over a wide area and for many weeks has maintained a succession of club-like clusters of blood-erimson flowers, curiously dull and heavy in comparison with the beautiful rose-pink of little *Spirea digitata* hard by and the still more elegant and airy plumes of diminutive *Astilbe simplicifolia* in white, faintly suffused with a hint of blush.

Although conditions have been so advantageous for most of the rock garden *Violas*, the incomparable *gracilis* carrying on until well into August, none of these have maintained such a long period of blossoming as *Lady Crisp*, which is still a mass of bloom. This charming thing, in a cool blue-lavender, suggests in foliage and flower a near relationship to *gracilis* and the same must be said of the pale yellow, exceedingly chaste, *Perry's Yellow*, which has only just ceased flowering. *V. bosniaca* is also repeating the earlier brilliance of its vivid crimson blossoms and *Papilio*, of the *Cornuta* type, but much less rampant, is faithful to its traditional all-season blooming and the estimable habit that it has of never inter-marrying with its neighbours, though it reproduces itself so freely by seed.

Among the *Thymes* and divers others after their kind, *T. erectus* is now covered with white flowers, while among several *Micromeris* (or is it *Satureia*?) the confusion of whose names is beyond me, there are none which are other than perfectly satisfied with the aftermath of our hapless summer. *Calamintha grandiflora* has entered upon a second flowering, the fine rich purple blossoms being even finer than before. It is noteworthy how these and other *Labiates*, like the shrubby *Salvias*, *Peroyskii*, *atriplicifolia* and others, though usually considered suitable plants for dry, warm land, do so much more satisfactorily in our soil when the weather is wet during the flowering period.

Many of the *Cistus*, notably *cobariensis*, *lusitanicus* and *salvifolius* in white and crispus in rose are still in full flower, having produced an entirely new set of flowering shoots after their normal blooming season was over. As for *C. lalmifolius*, with its 12in. sprays of blossom, it is a blaze of yellow and looks like continuing well into late autumn. Where the greater space that is essential can be afforded, this is a freer and hardier species than *C. algarvensis*, which it somewhat resembles. Another shrub which has given us a good second crop of flower, despite the fact that it set seed freely at midsummer, is *Fremontia californica*. *Dendromecon rigidum* is at its best, and its beautiful rich yellow and fragrant poppy flowers never look quite so attractive as they do in autumn. *Desfontainia spinosa* could scarcely carry a heavier burden of its wonderful scarlet and yellow trumpets and it will flower well into late autumn. *Clethra almitolia* and *acuminata* have responded to the wet season by blooming with exceptional liberality, and another shrub which is always especially fascinating at this season is *Diplacus glutinosus*. *Solanum crispum* var. *autumnale*, which commenced flowering in May, is preparing for a second display of its pretty blue-lavender flowers, but *Sollya heterophylla*, on a south wall, having had insufficient sun, is only just about to open the first of its belated blue bells.

The *Clematis* season has been greatly prolonged, but I must confine my notes here to two plants. The one is the elegant *C. tangutica*, its graceful foliage clinging to an Ivy-clad wall and covered with not only a generous late crop of its rich yellow flowers, but the delightfully silky and iridescent seed pappus of the earlier blossoming. The other is *C. Comtesse de Bouchaud*. This is a large-flowered hybrid in an uncommon bright satiny rose, but it is notable not only for its colour, but the

abundance of its flowers and long period of blooming. Though now about ten years old the plant referred to (and illustrated) has every season borne an enormous mass of blossom from June to the present time. This year it is especially good, it is now full of flower and still has succulent buds coming

on to carry its season to the last days of autumn. Many other hybrids may be as early and as late as Comtesse de Bonchard, but no other hybrid Clematis here has maintained such a long succession of heavy flowering without a lapse as this one.

N. Wales.

A. T. JOHNSON.

Anemone-flowered one turns naturally to the Collarette type which, though it photographs badly, is, in its better forms, an attractive garden flower. The new semi-double Collarette variety called Novelty is particularly bright and pleasing, the contrast between the brilliant crimson of the main petals and the clear yellow of the collar being very attractive.

The full garden value of the Dahlia is even yet not fully appreciated. It has two drawbacks which have hitherto restricted its popularity. Perhaps raisers may in the near future do something to minimise both. They should certainly bear them in mind. These weak points are lateness to flower, and an inelegant foliage. Lateness to flower, remembering their vulnerability to frost, is a big disadvantage and the purchasing public would, in a garden plant, forgive a little imperfection of form if the colour were right and the plant were noticeably more early flowering than the average. Much has been done to improve the Cosmos, which suffered from the same neglect. Surely it is the Dahlia's turn now!

As regards foliage, improvement is likely to be a long business, since one cannot safely predict what sort of foliage the produce of a certain cross will display.

All the Star Dahlias so far produced are beautiful. Their selection is largely a matter for individual preference, but the new Dorking Star, silvery mauve, with a crimson eye (illustrated in last week's issue, page 466), is a distinct and beautiful addition. Quite indispensable are White Star, Yellow Star, Infield Star (pale pink), Cuckfield Star (soft yellow and rosy buff), Mauve Star, and Crimson Star.

THE EVER-IMPROVING DAHLIA

THOSE florists who worship the goddess size, whether in Gladiolus or Sweet Pea might, if they would, learn a lesson from the Dahlia. Is there anything more clumsy and ugly in appearance, despite, in many cases, its charming colouring, than the old Show or Fancy Dahlia so much in favour less than three decades ago? Yet, how beautiful and decorative a flower it is when reduced to a mere fraction of its bloated size, equipped with an adequate stalk and called a Pompon! In every respect, except in size, the two types of flower are the same, yet what a difference! Even the purely formal triangles of blossom used for exhibiting the Pompons at the Dahlia Show cannot hide their grace and beauty. It seems strange that these little gems are not more grown.

Unquestionably the greatest advance in public favour of recent years has been made by the light and graceful Star Dahlias. This is not to be wondered at. It would be singular had they not become increasingly popular. There is now a very wide range of colour in this beautiful type. Probably a good deal of this popularity has been achieved at the expense of the more "set" looking

exhibition singles, but a deal has certainly been won from the heavier Cactus and Decorative types. These latter are "feeling the draught" in another direction. The Peony-flowered Dahlia is being steadily improved, especially as regards strength of stem and poise of flower. In its present form it is particularly welcomed for use in the mixed (but mainly hardy) flower border, which has largely superseded the herbaceous border pure and simple. The new Miniature Peony-flowered type is another instance of the difference which comparative size of flower affords. The Miniatures are hardly likely, however, to supersede the typical large Peony-flowered sorts. They are far more likely largely to replace for garden purposes the Garden Cactus and Decorative varieties. The latter, indeed, must expect a menace in another direction, as the new Camellia or Miniature-Decorative class becomes more numerous.

There would seem to be an opening, too, for the Anemone-centred type which, though by no means of recent introduction, seems not, hitherto, to have made much progress. With the Dahlia as with the Chrysanthemum, new additions to this class should be assured of a warm welcome. From the

A TYPICAL STAR DAHLIA, MAUVE STAR.

SEMI-DOUBLE CRIMSON AND GOLD, DAHLIA NOVELTY.

AUTUMN COLOUR IN THE SHRUBBERY

(Continued from page 460.)

OF the newer Cotoneasters of more erect habit probably *pinnosa* and *applanata* are the best, but *acutifolia* and *Francheti* are both interesting and beautiful. So, for that matter is the old and sometimes despised *C. Simonsii* and the old but not often seen *C. rotundifolia*. *Cotoneaster frigida* makes a handsome small tree with multitudes of berries. There is a yellowish fruited form which is interesting but not striking in the shrubbery. *C. Henryana* has the merit of rather large evergreen foliage.

Few berried plants are more effective than the Sea Buckthorn, *Hippophaë rhamnoides*. Nor is its value confined to fruit laden beauty in autumn. The silvery-grey foliage is admirable as a background for many shades of brilliant colour, some of them not too easily accommodated in the garden. It should be borne in mind that this plant is dioecious, so that at least one male tree should be included in every group, or if massed largely, to every half dozen or so of female specimens. Unhappily groups of this have been known to be planted which ultimately turned out to be *all* male trees. Hardly a testimonial for the firm which supplied them.

Valuable for their jelly as well as for their intrinsic beauty, no garden is complete without some of the large fruited Crabs. Transparent, Red Siberian, Yellow Siberian, John Downie, Fairy, Transcendant and *cerasifera*, all are beautiful.

Visitors in autumn to the Scottish Highlands cannot but be impressed by the beauty of the Rowan, which we English, illogically enough, too often call the Mountain Ash. On the fat lands of the South, the Rowan is less effective, though still valuable, but it is seen to best advantage on sweet, but rather poor land. It is worth a little trouble to secure a good coloured form as this tree varies considerably in berry colour. Indeed, there is one quite useful variety with orange-yellow berries. Nearly related to the Rowan is the beautiful *Pyrus Vilmorini*, which was illustrated in *THE GARDEN* of October 8, 1921, page 501.

Of fruiting shrubs surely the most brilliant is the Spindle Tree, *Euonymus europæus*, with its coral fruits and bright orange exposed seeds. Probably more graceful and even quaintier is the American representative of the family, *E. latifolia*, but it is hardly so showy as the Spindle Tree. It should be borne in mind that both species are practically dioecious.

Writing of dioecious trees brings to mind the *Pernettyas*, so valuable on light soils for berried effect. These are readily raised from seed and shew a considerable diversity in colour and size of berry, but, on an average, about 75 per cent. of the plants so raised turn out males. Seedlings, however, are very prodigal with offsets and a good stock of female plants may quickly be worked up. The pure white *Pernettya* is valuable as a contrast to the crimson and rosy forms.

White berries are certainly effective because of their contrast with foliage. Herein lies the value of the Snowberry, *Symphoricarpos racemosus*, which otherwise is rather a weedy-looking shrub.

The value of berried Holly needs no elaborating, though its effect is more in winter than in autumn. The common green Holly usually berries best and it has a counterpart with yellow berries. This season all female variegated Hollies are bearing berries freely, which reminds us that Golden Queen is a male Holly! Sufficient attention is not usually paid to the beauty of the Weeping Holly, especially the green one. Observant people will have noticed

that this form—sometimes male and sometimes female—is not uncommon in hedgerows.

Very beautiful effects can be achieved with the great variety of Rose hips, always provided

The brilliant colour and wonderful gloss are outstanding. All the coats of paint and varnish of a first class coachbuilder could not hope to rival it. The single white form seems to fruit

BERRIES AGAINST EVERGREEN FOLIAGE, COTONEASTER HENRYANA.

THE WHITE FRUITS OF THE WOLFBERRY, SYMPHORICARPUS OCCIDENTALIS.

that the birds will allow them to remain awhile when mature. This, in many districts, however, they will not. Despite the many new introductions, the most handsome species in cultivation, from the point of view of its fruits, is the Japanese Rose, *Rosa rugosa*. It is not merely the size of the fruits which makes this species so effective,

equally as well as the typical purplish mauve. The Sweet Briar, *R. rubiginosa* and the Penzance hybrids, fruit freely and the fruits are handsome, though less so, perhaps, than those of the Dog Rose of our hedgerows. The clusters of hips on that beautifully foliaged Rose, *R. rubrifolia*, are lovely, though being deep crimson, less showy

than some, while the singular fruits of many Asiatic species, such as *R. R. macrophylla* and *Movesii*, attract by their singularity.

The Butcher's Broom, *Ruscus aculeatus*, is very beautiful when covered with its brilliant berries, but this again is a dioecious plant and it is necessary to have both male and female plants if fruits are to set. The fruits of the Laurel and Aucuba are showy enough in themselves, but not effective in the shrubbery, those of the Mezereum perhaps more quaint than beautiful. Of fruits, beautiful but not particularly showy, the following deserve mention: those of various Araliads, such as *Fatsia japonica* and the *Acanthopanaxes*, with ivy-like berries, green or black, and also of the tree *Jvies*; of the various Privets, *Ligustrum*, lustrous black; of the Honeysuckles, mostly red, but sometimes blue-black; and of the Elderberries, *Sambucus nigra*, black, and *S. racemosus*, red.

Many *Viburnums* have handsome fruits, but none surpasses and few equal our two native species in this respect. These are the Guelder Rose, *Viburnum Opulus*, and the Wayfaring Tree, *V. Lantana*, the former with red and the latter with black berries; these are red when partly ripe and the black and red berries side by side are effective. When procuring the Guelder Rose, care should be taken to procure the wild form, not the bloated, unfertile Snowball Tree (*V. Opulus sterile*). The brilliant berries of the *Skimmia* are fine for the American garden, but a sufficiency of male plants must be provided. Foliage colour is a subject worthy of a special article.

THE EVOLUTION OF THE GLADIOLUS—II

More about Primulinus Hybrids.

FOLLOWING my comments on the American and English hybrids of *G. primulinus*, it remains to describe a few of the best emanating from Holland. To the credit of the Dutch growers it must be said they adhere to the true characteristics of the *primulinus* type, but against that virtue many of the firms selling Gladioli have a nasty knack of mixing up their stocks with the result that one is never certain of varieties being wholly true to name. Last year I purchased a batch of a new yellow self hybrid which evoked such a peon of praise from its raisers that I was drawn, almost against my colder reason, into a deal. Out of a dozen bulbs one came true to what I take to be the variety itself, a nice deep yellow, fair in form, nothing else. The other eleven were pathetic looking weeds, whose latter end was the rubbish heap. The one specimen, true to name, was not cheap!

Of all the Dutch group I like the *Krelage* issues best. They, like all the worth-while sorts from that country, make no sacrifices on the altar of size. Neat in shape, well placed on the spikes and full of colour, few raisers have done better work along this line than the firm of *Krelage*. *Adonis*, brilliant scarlet, effective for vase work or for border decoration, is one of the newer ones and still a little expensive, but *Alante* is cheap and is

also a remarkably pretty flower in salmon orange, with a small gold blotch. *Daphne* and *Niobe*, introduced, like *Adonis*, last year, are great favourites with all our visitors and I think I like them best of the lot. The former is fiery orange red with purple blotch, and the latter, brilliant orange scarlet in the wings, has a very tetching suffusion of lurid bronzy yellow in the lower segments, giving the flower a distinct and attractive appearance. *Letitia*, salmon pink, and *Latonia*, soft rose, come within range of the more delicate tints, but in *Psyche*, *Sphinx*, and *Scarletta*, we have a grand trio in strong tones of salmon rose, scarlet red and dazzling scarlet respectively. *Salmonea* is self-descriptive, but there is an orange glow in it which makes it something more than mere salmon in colour and it is a gem under artificial light.

The name of *Grullemans* must always stand high among Dutch growers if only for their introduction of the three beauties whose price puts them within reach of the pauper almost. *Maiden's Blush*, *Orange Brilliant* and *Sunrise*.—*Maiden's Blush* is of loveliest, softest pink. What more beautiful could a description be than just its name! and it maidens do not blush much in the twentieth century, you can still find the colour in the cheeks of the healthy tennis girl. *Orange Brilliant* is small flowered, dainty, *chic*, robed in

A BEAUTIFULLY RUFFLED PRIMULINUS GLADIOLUS—LINTON.

BRILLIANTLY COLOURED—ALMOST SCARLET, *G. ZENOBIA*.

a garment as glorious as a sunset off Cape Sparte and a deal cheaper to obtain for residents in these isles. This little one, and Nydia from America, are the two most exquisite flowers for room decoration one can well imagine to exist. Sunrise is a larger flower as may be gathered by the picture of it here, but there is nothing heavy about it. Its colours, in fact, suggest something of the buoyancy of sunrise as against the restful depth of sunset glow. This particular Sunrise augurs fine weather—a radiance of sulphur yellow and pink; and it, too, makes a very nice centre to the dinner table, so it serves the useful and double purpose of keeping

GLADIOLUS SUNRISE.
SULPHUR YELLOW AND PINK.

up the spirits and giving a whet to the appetite. Gralleman also gave us Insurpassable, a word of some *naïveté*, but the Britisher can none the less imagine its meaning and it hints at the quality of a very fine flower, a different kind of pink from Maiden's Blush, a Caroline Testout pink, bright and clear. Kitty Gralleman and Tea Rose are both of very softly blended colours, with yellow and orange predominating, the former almost passing into a buff shade. From the same source too, Rose Luisante, another happy name, carrying the picture of the flower into the mud at once. Another Dutch introduction worth having is Souvenir, real golden yellow, with just a little of the frilled edging that lends an "air" to so many of the American sorts.

Touching the other two varieties illustrated I wrote appreciatively last autumn in these pages about Linton, one of the frilled or ruffled hybrids from America. This flower caught the eye of Mr. Wallace of Tunbridge Wells at one of our earlier exhibits this season at Vincent Square. He considered it one of the best of its type and it certainly

is a fascinating flower with a very beautifully marked throat. Zenobia I mentioned in my last notes as being a hybrid of richest colouring, an orange red, approaching scarlet, but I might

substantiate that by saying that it forms a beautifully proportioned tapering and slender spike which makes it very adaptable for decorative purposes. J. L. GIBSON.

ESSENTIALS OF GARDEN DESIGN

IV.—Restfulness.

TO great extent Restfulness in a garden is not in itself a principle of design. Rather is it the end of other principles, the ultimate aim to which all sound principles of design tend. So important an end is it, however, that it may be wise briefly to consider what makes for repose in a garden.

In nine cases out of ten an "uneasy" or "restless" garden derives some of its unfortunate quality from "spottiness." Such spottiness may be brought about by bad general design or by bad detail in planting. We have all of us seen the herbaceous border, probably the apple of its owner's eye, and with the plants quite well grown and yet which produced in our minds only feelings of repugnance and regret that excellent materials should be so badly and distractingly employed. There is no necessity to labour the point. The planting of herbaceous borders in bold groups has become the correct thing to do and, like the "mason's yard" rockery, the spotty border will soon become extinct. Again, we have all seen the herbaceous shrubby border laid out by the man who, "abhorring straight lines" and not having the wit to employ bold and gracious curved ones, finished his border with little meaningless rounded teeth like those on a worn scythe blade. This latter is perhaps further from utter extinction because people without the slightest constructive ability will attempt to lay out their own gardens. To "lay out" a garden or to design *anything* for that matter, something more is needed than critical ability. There is all the difference in the world between knowing what looks right or seems wrong and being able to design correctly. Nothing is more astonishing than the ease with which educated people who would frankly admit their inability to lay bricks, for instance, "because they had not been taught," will take it for granted that they can, without any special knowledge, satisfactorily lay out their own gardens and, permission granted, their neighbours' also!

Spottiness is usually brought about by senseless repetition. The more beautiful and important the plant or material employed, the less it will bear repetition. Ribbon borders of *Violas* in their place look quite restful and satisfactory, but *Lilies* treated in the same way lose more than half their attractiveness. The *Viola* is a beautiful flower enough, but in some way one realises its subservience and its fitness for producing a continuous mass of colour. With the gracious *Lily* it is quite otherwise. Even the *Rose*, beautiful and graceful though in some forms it be, may well be used for producing massed colour. Not only the dwarf *Polyanthas* with no special beauty of floral form, but some of the most exquisitely shaped and coloured *Teas* and *Hybrid Teas* may be used in formal beds to produce masses of crimson, pink, white or yellow. Yet no one could contemplate with equanimity a double or treble row of giant bushes of *Alister Stella Gray*, for example! Wherein then lies the difference? Surely it is mainly one of height. By close pruning those *Roses* usually employed for bedding may be kept quite dwarf. They may then be treated as subservient, though a close inspection will reveal the individual beauties of the flowers.

Speaking very generally, monocotyledonous plants are less suitable for subservient massed effects than the dicotyledons. *Lilies*, *Gladioli*, *Irises*, *May-flowering Tulips*, *Torch Lilies*, *Yuccas*, *Pampas Grasses*, *Arundos*, *Bamboos* and *Palms* should all be used in comparatively small groups, so that graceful habit or elegant blossoms may be seen to greatest advantage. Exceptions to this rule are early-flowering and dwarf genera and species such as *Crocuses*, early-flowering *Tulips*, *Hyalanthus*, *Narcissi*, and such *Irises* as *reticulata*, *pumila* and the dwarf ones of the *Bearded* group. Even so, *Iris reticulata* is too beautiful in itself to use merely as an edging or foil to other plants. Though grouped boldly, it should be treated as the effect in itself, not as a means to its attainment.

Of dicotyledons of the highest class the number is smaller, and the list would include few truly herbaceous families or species, though obviously such sub-shrubby plants as *Romneya* or *Lavatera Olbia* would hardly be employed in a subservient capacity.

Leaving plants quite on one side for the instant, the repetition of ornamental features in stone or wood will be distracting and displeasing, always supposing the objects referred to *have any particular individual beauty*. We may safely use a pleasing stone paving to any extent which seems called for by comfort or convenience, but the repetition of statuary, fountains, sundials, pergolas or what not can only be unsatisfactory. Not only does such overuse make for lack of repose, but it prevents proper appreciation of the individual specimens. The use of statuary at intervals along the top of an important terrace wall is a possible exception to this rule, but the writer has doubts as to its legitimacy, and in any case it is a question of little more than academic interest in these days of comparatively small houses and gardens. The abuse of noble materials by using them for entirely subordinate purposes is one of the commonest causes of want of repose. It is the old disadvantage of marble halls which were surely built rather to admire than to live in!

Speaking generally, a hillside garden is less restful than a moderately level one. Not that, unless the garden be absolutely cliff-like, it need be otherwise than entirely satisfactory in this respect, but to produce a reposeful effect it must be adequately terraced and the general up and down contour of the garden should be concave, otherwise unsatisfactory, badly arranged and unrestful glimpses will take the place of what should be a comprehensive view of the lower levels from above. The breaking of the terraces by belts of trees to define vistas or to frame more distant views is, of course, quite a different matter and bears no relationship to this viewing of part of a scheme of planting with the foreground left out.

Almost everyone will have remarked the restfulness which appears to attach to the average sunk garden. To great extent this is due to the hollow (concave) outline such a feature imparts to the garden as a whole. Certainly nothing is much more unfortunate than a garden which is constructed around a mound, unless, of course, the house cap the mound, when by suitable terracing magnificent effects can often be attained.

Too much colour, particularly a surfeit of garish colour, will make the best designed garden uninteresting, especially if it be badly placed. The present fashion for the brilliant orange, apricot, hot salmon and other similar shades is good in itself. There is no harm in pure strong colour, so it be properly used, but it must be confessed that a little of such colouring goes a long way. In a garden an abundant setting of green and, in addition, some preparation of cooler colouring is needful properly to appreciate it. Colouring need not be strong to be pure, let it be remembered; indeed, some exceedingly brilliant colour is anything but pure, witness Crimson Rambler Rose and the Rock Purslane (*Calandrinia*),

for instance. Real crimson as seen in such flowers as *Lobelia fulgens* or crimson Snapdragons is at once rich and restful, but the colouring of *Geum Mrs. Bradshaw* or of some Torch Lilies (almost brick-red) is difficult to arrange without clashing, and in any case, unless used in strictest moderation, very tiring to the eye. Properly used there is no harm in the colouring of Paul Crampel *Pelargonium*, though in combination with blue *Lobelia* and white *Marguerites* it produces a harsh "starched collar" effect anything but pleasing to an educated eye. Yet for lighting up what might otherwise be a drab and uninteresting corner this plant has few equals, and its colour, though brilliant is not garish.

NOTES ON DAFFODILS

The late Mrs. Berkeley of Spetchley.—Giant Leedsis.—Carnation.—Bernardino.

I SIMPLY cannot begin these notes after having read the account of Mrs. Berkeley's (of Spetchley) death without writing a few words to express the deep sorrow which I and all who were privileged to know this singularly quiet and lovable woman must feel at this sad event. I little thought when I saw her in her car outside the Hall in Vincent Square this spring that I would never see her again, and that it would be the last season for her beloved Polyanthus to have her to tend them. Under her own guidance I have seen the long wide borders in which they grow in the old kitchen garden at

Spetchley Park. I have seen, too, the stretch of choice Daffodils in another part of the grounds which told of the persistent interest of one of our earliest "amateurs" in these flowers. Of the ancient trees of historic interest; of the newest of the new plants to be met with in the woodland; of the fame of the gardens and their "ingenious" owner in the distant days of John Evelyn (Evelyn's "Kalendarium," eighth edition, 1691, page 68); of *Ribes Jessoniae*; and of many other matters it would be out of place to say more in a Daffodil article. I will just remind readers that in the years 1902 and 1903 Mrs. Berkeley won the first

prize in the fifty class at the Midland Show, following these successes up by winning the first prize for twelve new varieties in 1904. The varieties shown were *Silhou*, *Rhymster*, *Earl Grey*, *Sir Francis Drake*, *Robert Berkeley*, *Great Warley*, *Eleanor Berkeley*, *Aurora*, *Countess Grey*, *Charles Wolley Dod*, *Incognita* and *Noble*. In 1922 she got an award of merit for the exquisite white trumpet *Robert Berkeley*. It is a big jump 1904 to 1922, but it shows that she had still an eye for a good flower, and that her early enthusiasm and interest had not abated. The Daffodil has lost one of its earliest and best friends, and the human world is the poorer, for of her it may truly be said in the self-same words with which Jean Ingelow describes "my some's wife, Elizabeth" in her pathetic description of the devastation caused by "The High Tide on the Coast of Lincolnshire" in 1571, a "sweeter woman ne'er drew breath." *Requiescat in pace.*

GIANT LEEDSIS.

How is it that all the Giant Leedsis keep so dear? I see the old *White Queen* offered in one

THE BEAUTIFUL DOUBLE NARCISSUS CARNATION.

NARCISSUS BERNARDINO, A GIANT INCOMPARABILIS.

GIANT LEEDSIS NARCISSUS PHYLLIDA.

catalogue at five shillings a dozen and in another at six and six, but after that there is a jump to ten and six, ending up by a sovereign for *Kingdom* (Sydenham) and a guinea for *White Pearl* (Barr). We want more of the five shillings. They would then go off like hot cakes. This type of Daffodil is one of our modern creations and was unknown until Engleheart suddenly produced *White Queen* before an astonished world. The whole tribe, more especially the taller ones like *The Fawn* and *Kingdom*, make grand garden plants, and I feel sure when the drop comes they will be, as undoubtedly they ought to be, planted as freely as that grand old hybrid Emperor, *Phyllida*, which was raised by Mr. W. F. M. Copeland, received an award of merit for show in 1916 along with *White Pearl* and *White Pennant*, both Giant Leedsis. In my notes I see I classed it as an *Incomparabilis*, but Bath's, who now hold the stock, class it as a *Leedsis*. There are several of these border-line varieties which are

as difficult to place as a horse in the Grand National. Phyllida has the look of a glorified Minnie Hume with a gramophone shaped lemon cup, which with age fades to a primrose. The perianth segments are pure white, and are alternately rounded and pointed.

CARNATION.

One is glad to have the opportunity of saying a good word for an old friend. It came from the highly favoured county of Cornwall, where atmosphere and tempered sun work together for the Daffodil's good. It can live and flourish elsewhere though, and a prettier double no one need wish to see. The palest of buff-coloured petals with the little orange-red tongues of flame at their base form a happy combination which experience has proved to be constant. The flower has in well grown specimens a diameter of 4ins.

BERNARDINO.

In a Bernardino year there is very little doubt about Bernardino being one of the most beautiful

of all Daffodils. If only the exquisite ruddy apricot of its large cup had the staying power of the red in the cup of Lucifer, the ointment would have no fly. This last season I am told our few flowers here lacked colour. No doubt it was the result of the cold inclement weather that everyone seems to have had during March and April. So to anyone who only knows Bernardino from seeing it in 1922, I say, "Please do not judge it by what you saw then," and Bernardino itself says, "I am not a politician and my order habits are good." Character paper.—Health and constitution: Excellent. Shape, size and height: All that could be desired. Perianth: White and imbricated without stiffness. Behaviour in the open: Splendid. Behaviour under glass: Indifferent. Any other remark: Buy it even if it costs you half a dollar. The above facts are true to the best of my knowledge and belief—Narcissus incomparabilis, foster-parent of the above-described Bernardino incomparabilis major. JOSEPH JACOB.

is omitted and we get, as in the heading of this note, simply *Ixiolirion tataricum*, *Ixiolirion Pallasii* or *Ixiolirion Ledebourii*. It only means a difference in shade. I grow them in 5in. or 6in. pots in an all but cold frame; but they are very nearly hardy, as in a made bed of light soil they have survived a mild winter. They are much of a muchness with *Freesias* in their height of flowering stem, but they have not the sun-stiff, small, sword-like foliage. Their leaves are long, linear and arching. All the same, a friend seeing a vase in my study exclaimed, "I say, what have you got here, blue *Freesias*?" He might better have said "pretty purple," but *Freesia* is a trifle nearer the mark than *Ixia*.—JOSEPH JACOB.

A TINY GOLDEN-FOLIAGED BEDDER.

THOUGH the Sandworts are rightly regarded as rock garden plants, the golden variety of *Arenaria caespitosa* can be utilised in quite another way, as may be seen in the make-up of the floral clock that attracts its thousands daily in West Princes Street Gardens, Edinburgh. Although carpet bedding is all but a thing of the past, this pretty little plant is quite suitable for a dwarf edging plant on well drained soils; it is easily increased by division.—CALEDONIA.

SWEET PEA ROYAL SCOT.

I CRAVE a small amount of space to acknowledge Mr. Harry Scholefield's courteous correction (page 455) of an error which lead me to

do an injustice to one of the most beautiful and useful of Sweet Peas. I have proved Royal Scot to be one of the kindly varieties in that it grows vigorously in almost any soil, flowers profusely provided that it is closely gathered, and it does not burn in the least—on the contrary, it shines out in full glory only when the bright sun is shining directly upon it.—H. L.

THE FLORISTS' RANUNCULUSES.

REFERRING to Mr. Jacob's remarks on the subject of Ranunculuses (page 451), I agree with him that they are difficult. Even when grown in soils and situations that suit them they seem to be very sensitive to unfavourable climatic conditions, the character of the weather during the time

would have been called *Campanulolirion* or the Bell-flower Lily. In both form and colour the *Ixiolirions* remind me so much of *Campanulas*. Very likely if I had a wider acquaintance with this huge family I could get a perfect match as far as the individual flowers go, but their umbel arrangement is the peculiar adjunct of the Lily. It, however, lacks the measured stiffness of a *Nerine* or the Wild Garlic of our hedgerows. It has a slightly dishevelled look, and this gives it a charm akin to that of the ideal flower-seller of the street as against that of the stately flower-wearer at a "swell spread." Catalogues confine themselves to some variety of the species *montanum*, all of which are of some shade of campanula purple. Usually *montanum*, the specific name,

they are making growth determining success or failure. Although fond of sunshine they seem to dislike the cold, dry atmospheric conditions which frequently go with it in springtime, and a spell of east wind is very bad for them, even if the plants are sheltered from it. I am so fond of them that I always plant a few every year, although I have frequent failures with them. Has Mr. Jacob tried them in pots? If not, I can recommend him to do so, for they make charming little specimens grown with three tubers in a 48. I pot mine late in autumn in light, rich soil, keep in a cold frame until about the end of February, and then put them in a cool greenhouse near the glass until the flower buds are ready to open. I am more successful with them in this way than when trying to grow them in the

CORRESPONDENCE

THE TAMARISK.

I WONDER why that interesting and beautiful shrub, the Tamarisk (*Tamarix gallica*), is so conspicuous by its absence in our gardens? I have visited a large number of gardens, great and small, in the East of Scotland and I have only come across this plant in three of them, viz., the Edinburgh Royal Botanic Garden, a villa garden in Portobello and another in Musselburgh. In all three the soil is of a sandy nature, to which the plant is undoubtedly partial, but I fancy it would succeed quite well in any loamy soil, in fact, Nicholson says: "It will thrive under almost any conditions." It is a very suitable plant for the shrubby or wild garden, its catkin-like spikes of pink flowers being very attractive.—CHAS. COMFORT.

THE "CLOVE" REDIVIVUS.

THE old dark crimson Clove is dead: long live the Clove." Mr. James Douglas is "following in the footsteps of his dear old dad," and Great Bookham is still a most important centre for the choice border Carnation. Not the least service that the son has rendered to his fellow-gardeners is his evolution of the new race of Bookham Cloves. Just when we were bemoaning the loss of our old grandmother's plant—the dark sweet-scented crimson Clove—Mr. Douglas comes along and places before us this new race. One and all have that same spicy aroma which the old plant had so abundantly, but they have not all got it in the same degree. From personal observation I should place White Clove first and Blush Clove second. The perfume of the white is very strong. There is, however, another pure white variety called Crystal Clove which, as far as looks go, might be chosen in preference: but it would be a mistake if it is scented, more than perfection of form, that is the great desideratum.—MAELOR.

A SPLENDID CUT FLOWER.

HOW seldom one comes across that ideal flower for cutting, *Ixiolirion tataricum*, in the gardens of our friends, and yet a nicely arranged vase is bound to please the most fastidious unless, ladies, it is that Moloch of a drawing-room which imperiously calls upon you to sacrifice so many beautiful flowers before his coloured altars. Alas! drawing-rooms, bedding out and colour schemes have many plants to answer for. One that I hope will escape the holocaust is this *Ixiolirion*

A VASE OF IXIOLIRION TATARICUM.

open ground, probably because the conditions are more under control. Both the Turban and French sections do well in pots. I have not tried the Persian kind, but see no reason why they should not succeed also.—A. D. FORT.

THE LIGURIAN HAREBELL.

WHY is *Campanula isophylla* reserved almost entirely for greenhouse and conservatory? In the rock gardens of Raby House, near Chester, it blooms profusely, forming long streams of starry blue and white, the typical lilac blue *isophylla* being mixed with the white variety. It is also flourishing on the walls, which are built somewhat differently from the usual stone wall, the stones being set decidedly on the slant and so catching a liberal amount of moisture. Among other plants that have bloomed remarkably well is *Sisymbrium Bermudianum*, which is situated in a semi-shady position beside the stream. This charming plant commenced flowering early in June and still opens its petals to the sunshine. *Primula involucreata* and *P. kewensis*, after a short rest, both again attract the eye.—GERRY.

FROM JAPAN.

TO Japan we owe many of our most attractive flowers and it is from that land that the subject of this note, *Anemonopsis macrophylla*, has come to rejoice the hearts of flower-lovers who are devoted to hardy plants. It must be many years since first I saw the *Anemonopsis*, and it must be some seventeen or eighteen years since it was added to my garden. Yet it is not by any means a common plant, although I have always found it quite hardy and moderately free-flowering. I say "moderately" free-flowering advisedly, as it is not a plant which covers itself

with bloom, after the manner of many plants. Yet it gives a fair number of its pleasing flowers for a considerable time in late summer and autumn. In appearance it affords some justification for the generic name, as it is really "Anemone-like," and many take it to be one of the charming race of Windflowers. The blooms, which are of a form resembling in a far-off way those of a Japanese Anemone, are much smaller than those of *A. japonica*, and are of more substance. They are in some plants white and in others tinged with lilac, but I have never come across a plant with flowers of lavender blue, such as is described by the late Mr. Farrer. But that departed writer is correct in drawing some resemblance from the glossy foliage to that of an *Actaea* or *Cimicifuga*. Mr. Farrer apparently considered it rather difficult, but the present writer has found it easy to cultivate on ordinary loam, and the other day he saw a good plant in a rock garden, flowering freely and apparently quite happy. It was one of the forms with lilac-tinged blooms. A height of 14 ins. is given in some works, but I have seen it rather more and as little as 6 ins. or so.—S. ARNOTT.

HARDY CRINUMS.

OF the behaviour of *Crinum Powellii* in heavier soils I have no experience, but in a light sandy soil that is always well drained, it thrives amazingly. Some clumps that had stood for a number of years were lifted last November. The closely compacted masses of great bulbs were something like 2 ft. through and so heavy that after digging all round and loosening them, it was a two-man job to roll them out of their holes. Their main place, a border facing south backed by a 7 ft. wall, was freshly prepared and some of the bulbs replanted. Now, after nine months they are well in flower. Formerly I thought they were tender and gave them a winter covering of dried bracken, but this has proved to be unnecessary. The bulbs, planted at a good spade's depth, go down, so that when lifted they have a white neck a foot or more long. They are wonderfully tenacious of life. A heap of damaged bulbs, some of them chopped in half in dividing the clumps, were thrown aside, on to an open border in the kitchen garden. Within three months they were all trying to grow. Roots were pushing, wounds had closed and looked perfectly healthy, and, where a bulb had been badly gashed, a quantity of young growth was forming, that looked as if it would become a cluster of small bulbs, just as a *Hyacinth* does when slashed across.
